Despite the fact that conserved currents have dimensions that are determined solely by dimensional analysis (and hence no anomalous dimensions), Nature abounds in examples of anomalous diffusion [1–2] in which $L \propto t^\gamma$, with $\gamma \neq 1/2$, and heat transport in which the thermal conductivity diverges as $L^\alpha$ [3–7]. Aside from breaking of Lorentz invariance, the true common link in such problems is an anomalous dimension for the underlying conserved current, thereby violating the basic tenet of field theory. We show here that the phenomenological [8–10] non-local equations of motion that are used to describe such anomalies all follow from Lorentz-violating gauge transformations arising from Nöther’s second theorem. The generalizations lead to a family of diffusion and heat transport equations that systematize how non-local gauge transformations generate more general forms of Fick’s and Fourier’s laws for diffusive and heat transport, respectively. In particular, the associated Goldstone modes of the form $\omega \propto k^\alpha$, $\alpha \in \mathbb{R}$ are direct consequences of fractional equations of motion.

I. INTRODUCTION

Although Lorentz symmetry is a fundamental organizing principle of the universe, it is oftentimes violated. For example, any collection of particles, complicated enough for a center of mass to be well defined, has a preferred reference frame and hence violates the boost-invariance of the Lorentz group. The lack of boost-invariance rarely occurs as a solo act. The continuity equation, derived from the continuity equation, is imposed. Substituting (3) into the continuity equation (1) results in the well known diffusion equation

$$\partial_t n - D \Delta n = 0. \quad (4)$$

The propagator for this equation has solutions even for space-like separations. Such growth is inconsistent with special relativity and hence must be associated with a massless mode, in this case $\omega = -iDk^2$. Arguments of this sort have motivated an extensive literature [13–15] on squaring standard diffusion with special relativity. A promising solution [16] appears to be random walks based on non-Markovian processes, as relativistic Markov dynamics in space is a misnomer. The inconsistency of diffusion with special relativity is also known in the context of linearized relativistic hydrodynamics where it manifests itself as the violation of causality – superluminal propagation. A famous resolution to this problem was given by Israel and Stewart[17] and it can be reformulated as an upper bound for the diffusion constant $D < \nu^2 \tau$ [18], where $\nu$ is the lightcone speed and $\tau$ the equilibration time at which diffusion obtains.

What the previous derivation lays plain is that the form of the current imposed by Fick’s law fixes the diffusion equation. However, Fick’s choice is not unique and, as a result, neither is the diffusion equation. In fact, there is an extensive literature, on replacing either the time derivative [10, 19] or the spatial Laplacian [8, 9, 20–23] in the diffusion equation with a pseudo-differential operator such as the fractional Laplacian. What results from such analyses are non-local diffusive transport or Lévy processes that are capable of describing the numerous experimental realizations of anomalous diffusion [1, 2, 24, 25] in which $L \propto t^{\delta}$, $\delta \neq 1/2$. Subdiffusion corresponds to $\delta < 1/2$, whereas superdiffusion arises when $\delta > 1/2$.

Anomalies also occur for heat transport which is derivable immediately from the continuity equation by substituting Fourier’s law for the gradient of the temperature profile

$$J_H = -\kappa \frac{\partial T(x,t)}{\partial x}, \quad (5)$$

where $\kappa$ is the thermal conductivity. From dimensional analysis $J_H \propto L^{-1}$ and $\kappa$ scales as $L^0$. However, since the pioneering

\* matteo.baggioli@uam.es
\† lanave@illinois.edu
\‡ dimer@illinois.edu
paper of Fermi, Pasta and Ulam [26] showed that even in an anisotropic harmonic solid \( \kappa \) diverges, numerous physical systems [27–30] as simple as single molecules [7] and nanotubes [3–6, 31] have been shown to violate Fourier’s law as they exhibit a thermal conductivity diverging as \( \kappa \propto L^\alpha \). Such a divergence of \( \kappa \) implies that the heat current scales as \( J_H \propto L^{\alpha-1} \). Only \( \alpha = 0 \) corresponds to standard diffusive transport. As in anomalous diffusion, fractional equations of motion [32–34] are also invoked to explain a heat current that scales with an anomalous power, \( J_H \propto L^{\alpha-1} \). What is surprising with the heat current is that the scaling \( \kappa^\alpha \) applies [35] even to the archetypal 1d diatomic hard-point gas implying that a fundamental non-locality underlies the heat transport even in this simple case. From the Weidemann-Franz law, any anomaly in the heat transport is passed onto the electrical transport. Equivalently, heat transport in charged fluids is governed by \( U(1) \) invariance and the derivation presented in the first section applies. The standard folklore [36] is that any current tied to a \( U(1) \) gauge field cannot acquire an anomalous dimension under any amount of renormalization. Hence, squaring any of the non-local schemes [27, 32–34] that have been devised to treat anomalous heat transport, that is \( \kappa \propto L^\alpha \) [3–6, 31, 35] or anomalous diffusion [8, 20–23, 32–34] must account for how they get around the standard argument that the dimension of the conserved current is fixed solely by dimensional analysis.

It is precisely this problem that we address in this paper. In previous work, we have shown [37, 38] that Nöther’s second theorem (NST) allows for non-traditional scaling of the current only if the action of the gauge group is changed fundamentally. However, all of our extensions of Nöther’s second theorem presented previously [37, 38] preserve Lorentz invariance and hence are not directly applicable to anomalous heat or diffusive transport. What we do here is generalize these arguments to the non-Lorentzian case. We focus on the minimal constraints that must be placed on the action of the gauge group to derive anomalous diffusive transport equations. We show that the phenomenological diffusion equations [8, 20–23, 32–34] have a rigorous basis in Nöther’s second theorem. This theorem stems from the simple observation that the continuity equation \( \partial_\mu J^\mu = 0 \) is unique up to any operator, \( \hat{Y} \) that commutes with the exterior derivative resulting in

\[
\partial_\mu \hat{Y} J^\mu = \partial_\mu \hat{P}^\mu = 0
\]

being an equally valid equation of motion (EOM). To be consistent, the operator \( \hat{Y} \) must also be present in the gauge-invariant condition. Stated succinctly, the second theorem finds that the full family of generators of \( U(1) \) invariance determines the dimension of the current not just the linear derivative term used earlier. In general, the second theorem applies anytime there are either a collection of infinitesimal symmetries or one symmetry parameterized by an arbitrary number of functions. More recent examples that fall into this category are fractons [39], exotic excitations with confined mobility [40]. Such anomalous behaviour was connected to the conservation of higher-order charges such as the dipole moment and to new tensorial symmetries [41–44] and follow necessarily from NST.

We have exploited the degeneracy implied by Nöther’s second theorem to show [37, 38, 45] that the most general formulation of electricity and magnetism is one with fractional equations of motion with full Lorentz symmetry. However, to describe diffusion, we need to restrict ourselves solely to a subset of operators that ultimately breaks Lorentz invariance explicitly. From our formulation, we see that the associated Goldstone is now \( \omega \propto k^\alpha \) with \( \alpha \in \mathbb{R} \). Goldstone modes with fractional powers have been observed previously as ripplon modes in a 2D Wigner crystal [46, 47], which have the same dispersion as plasmons in a 2D electron gas, and domain-wall fluctuations at superfluid-superfluid interfaces [48] as they obey \( k^{1/2} \) and \( k^{3/2} \) dispersions, respectively. In the context of the latter, a non-local action [49] containing the fractional Laplacian acting on the displacement field for the interface was proposed to generate the corresponding gapless boson dispersion. The appearance of the fractional Laplacian was justified based on an integration of gapless degrees of freedom [49]. We show here that such fractional dispersions result quite generally from Nöther’s Second theorem.

II. BACKGROUND

The power of NST in gauge theories can be understood from a simple degeneracy argument. Consider the Maxwell action,

\[
S = \frac{1}{2} \int \frac{d^4 k}{2\pi^2} A_\mu(k) \left[ k^2 \mu^{\mu\nu} - k^{k^\nu} \right] A_\nu(k)
\]

\[
= \frac{1}{2} \int d^4 k A_\mu(k) M^{\mu\nu} A_\nu(k).
\]

(7)

All gauge transformations appear as zero-eigenvalues of \( M \). For example,

\[ M^{\mu\nu} k_\nu = 0, \]

(8)

which yields the standard gauge-invariant condition in electromagnetism because \( i k_\nu \) is just the Fourier transform of \( \partial_\nu \). The ambiguity that leads to NST comes from noticing that if \( k_\nu \) is an eigenvector, then so is \( f(k)k_\nu \), where \( f(k) \) is a scalar which depends on the momentum itself. Whence, there are a whole family of eigenvectors,

\[ M^{\mu\nu} f(k) k^\nu = 0, \]

(9)

that satisfy the zero eigenvalue condition, each characterizing a perfectly valid electromagnetism (EM). It is for this reason that Nöther [50] devoted the second half of her paper to the consequences retaining all possible integer derivatives,

\[ A_\mu \to A_\mu + \partial_\mu \Lambda + \partial_\mu \partial_\nu G^{\nu} + \cdots, \]

(10)

in the gauge-invariant condition for \( A_\mu \) has on the conservation laws for the current. All higher-order integer derivatives generate new constraints on the current and correspond to new conserved conserved quantities for the current. To determine \( f \), we note the following. We now take \( \mathbf{p} \) to the the full 4-momentum. 1) \( f \) must be rotationally and Lorentz-invariant. 2) \( f \) cannot change the fact that \( \Lambda \) is dimensionless; equivalently it cannot change the fact that \( A \) is a 1-form. 3) \( f \) must commute with the total exterior derivative; that is,
we break the Lorentz-invariant condition on $f$, $p_d = 0$ just as $[d, \hat{Y}] = 0$. Hence, finding $f$ is equivalent to fixing $\hat{Y}$. A form of $f$ that satisfies all of these constraints is $f = f(p^2)$. In momentum space, $k^2$ is simply the Fourier transform of the Laplacian, $-\Delta$. As a result, the general form of $f(p^2)$ in real space is just the Box operator raised to an arbitrary power, and the generalization in Eq. (9) implies that there are a multitude of possible electromagnetisms (in vacuum) that are invariant under the transformation,

$$A_\mu \rightarrow A_\mu + f(p^2) i p_\mu \Lambda,$$

(11)
or in real space,

$$A_\mu \rightarrow A_\mu + (-\Box)\gamma \partial_\mu \Lambda,$$

(12)
resulting in $[A_\mu] = 1 + 2[f] = \gamma$. The definition of the fractional Laplacian and fractional Box operator we adopt here is determined by the general form of a differential operator $L$.

$$(L_c)^{\gamma} f(x) = \frac{1}{\Gamma(\gamma)} \int_{0}^{\infty} e^{-tL} f(t) \frac{dt}{t^{1-\gamma}}$$

(13)
where $e^{-tL}$ is the "heat" flow of the operator $L$, i.e. $\beta := e^{-tL} f$ is the unique solution to $\partial_\beta + L \beta = 0$ with Dirichlet boundary condition $\beta |_{x=0} = f$. In the case of the Laplacian acting on functions, one can prove this coincides with the standard Riesz definition

$$(-\Delta)^{\gamma} f(x) = C_{\alpha,\gamma} \int_{\mathbb{R}^n} f(x) - f(\xi)$$

(14)
for some constant $C_{\alpha,\gamma}$. Note, rather than just depending on the information of $f(x)$ at a point, the fractional Laplacian requires information everywhere in $\mathbb{R}^n$. For the Laplacian acting on differential forms, there is a similar formula which holds componentwise, as it was shown by the authors in [37]. The standard Maxwell theory is just a special case in which $\gamma = 1$. In general, the theories that result for $\gamma \neq 1$ allow for the current to have an arbitrary dimension, not necessarily $d - 1$, without spoiling its conservation nor violating Gross’ argument [36]. Identifying $\hat{Y}$ with the fractional Box operator yields the conservation law

$$\partial^\mu (-\Box)^{(\gamma-1)/2} J_\mu = 0.$$  

(15)
As expected, this ambiguity shows up at the level of the Ward identities. The current-current correlator for the photon

$$C^{ij}(k) \propto (k^2)^\gamma \left( \eta^{ij} - \frac{k^i k^j}{k^2} \right)$$

(16)
does not just satisfy $k_\mu C^{\mu\nu} = 0$ but also $k_\mu C^{\nu\mu} = 0$. This translates into either $\partial_\mu C^{\mu\nu} = 0$, the standard Ward identity, or

$$\partial_\mu (-\Box)^{\gamma-1} C^{\mu\nu} = 0$$

(17)
which illustrates that the current conservation equation only specifies the current up to any operator that commutes with the total differential. Conservation laws such as the one in Eq. (15) are in some sense more fundamental, as one can infer the standard ones from them, but more importantly they can occur earlier [37, 38] in the hierarchy of conservation laws that stem from Nöther’s first theorem.

### III. NON-LORENTZ INVARIANT THEORY

We start by discussing the form of the effective Lagrangian of a non-boost invariant theory (which may or may not preserve Galilean transformations). Such an effective Lagrangian can be written as

$$L = \frac{1}{2} \int d^4 x \left( C_{ij} F_{ij} C^{ij} F_{ij} + c F_{\mu0}^2 \right) + L_m,$$

(18)
where $C_{ij} F_{ij} = \int C_{ij}(x,y) F_{ij}(x) - F_{ij}(y) dy dx$ with $C_{ij}(x,y)$ a function of the 2 vector variable $x$ and $y$ (and we assume, naturally, that $C_{ij}(x,y) = f(|x-y|^2)$ in case the Galilean symmetry is not broken and there is no loss of generality in assuming that $c$ is constant. The matter-field Lagrangian $L_m$ also has to be of the form

$$L_m = \int \left( \int \left( c_1(s,t) (\partial_\phi^2)^2(x,s) \right) ds \right) d^4 x dt + \int \left( c_2(s,t) (\partial_\phi^2)^2(y) - c_3(s,t)(\nabla^2 \phi)^2(y) + \ldots \right) dy d^4 x dt + F_1(\nabla \phi - \phi) + F_2(\phi_0 - \phi),$$

(19)

and again without loss of generality, we can assume

$$\int \left( c_1(s,t) (\partial_\phi)^2(x,s) \right) ds = (\partial_\phi)^2$$

that in the case that Galilean symmetries are preserved, $c_\phi(x,y) = f_\phi(|x-y|^2)$. Further, the condition that boost symmetry be broken, is equivalent to requiring that the pseudo-differential operators $\int (c_1(s,t) (\partial_\phi^2)^2(x,s) ds$ and

$$\int (c_2(s,t) (\partial_\phi^2)^2(y) - c_3(s,t)(\nabla^2 \phi)^2(y) + \ldots) dy$$

be of different order.

Although most of our discussions apply to the general setting, nonetheless, for the sake of clarity, we will focus our attention on the case that the pseudo-differential operators are fractional Laplacians. To apply this framework to diffusion, we break the Lorentz-invariant condition on $f(p^2)$. In order to define the corresponding Lagrangian, we discuss a more general setting at first. We thus concern ourselves with the context in which we are given a mixed tensor $\Omega$ which for clarity of exposition we think of as being represented by a pair of tensors $A$ and $B$. In fact, since we are concerned with EM (or Yang-Mills theory more generally) we think of our mixed tensor $\Omega$ as being the sum of 2 differential forms $A$ and $B$. We assume that the underlying manifold separates as $M = M_1 \times M_2$. In this application, such a decomposition arises from the the switch from the Einsteinian to the Galilean perspective as a result of symmetry breaking. Correspondingly, $M = \mathbb{R} \times M_2$ in this case (in particular this occurs for globally...
hyperbolic spacetimes). This results in a decomposition on r-forms \( \Omega^r(M) = \bigoplus_{p+q=r} \Omega^p(M_1) \otimes \Omega^q(M_2) \). Our notation here corresponds to regarding \( \pi_i^* \Omega^r(M) \) (for \( i = 1, 2 \)) with \( \Omega^r(M_i) \); that is an element of \( \Omega^r(M) \) is understood as a linear combination \( \alpha_{1-i} dx^{i_1} \wedge \cdots \wedge dx^{i_r} \), where the \( \alpha_{1-i} \)'s are functions on the entirety of \( M \) and \( dx^{i_1}, \ldots, dx^{i_r} \) arise from coordinates on \( M_i \) only. Letting \( A \) and \( B \) be represented in coordinates as \( A = A_i dx^i \) and \( B = B_j dx^j \), we use a multi-index notation, where \( I = (i_1, \cdots, i_p) \) and \( J = (j_1, \cdots, j_q) \), so \( A = A_{i_1, \cdots, i_p} dx^{i_1} \wedge \cdots \wedge dx^{i_p} \), etc. The work horse of the non-Lorentzian picture will be the operator \( D_\gamma \).

\[
D_\gamma \Omega = d_1 \Omega + d_2 \Delta_\gamma \Omega = d_1 A + d_2 \Delta_\gamma \Omega, \quad A = A_{i_1, \cdots, i_p} dx^{i_1} \wedge \cdots \wedge dx^{i_p},
\]

where \( d_1 \) is the differential coming from \( M \), and \( \Delta_\gamma = d_2 d_2^* + d_2^* d_2 \) is the Hodge Laplacian on forms, where \( \ast_2 \) is the Hodge star operator on \( \Omega^r_2 \). This is clearly linear with respect to the decomposition of \( \Omega \) when \( \Omega = \alpha A + B \). Thus we analyse it in terms of its coordinates for a given form. Let us indicate coordinates \( x^i \) according to a separation arising from the split \( M = M_1 \times M_2 \). So we write the coordinates \( \{ x^i \}_{i=1}^n \) for those coming from \( M_1 \) and \( \{ x^{i_1} \}_{i_1=1}^m \) for the ones coming from \( M_2 \). Whence, in terms of coordinates, for \( A \) (and analogously for \( B \)), we have

\[
D_\gamma A = \sum_{i=1}^n \frac{\partial}{\partial x^i} A_i d x^i \wedge d x^i + \sum_{i=1}^n \frac{\partial}{\partial x^i} \left( \Delta_\gamma^{-1} A_i \right) d x^i \wedge d x^i + \sum_{i=1}^m \frac{\partial}{\partial x^{i_1}} \left( \Delta_\gamma^{-1} A_{i_1} \right) d x^{i_1} \wedge d x^{i_1}.
\]

In the special case (that we care about here) of breaking boost symmetry,

\[
D_\gamma A = \frac{\partial}{\partial x^0} A_0 d x^0 \wedge d x^i + \sum_{i=1}^m \frac{\partial}{\partial x^{i_1}} \left( \Delta_\gamma^{-1} A_{i_1} \right) d x^{i_1} \wedge d x^{i_1},
\]

where \( \Delta_\gamma^{-1} A_i \) is the fractional Laplacian on the spatial coordinates. In other words,

\[
D_\gamma A = d_1 A + d_2 \gamma A
\]

where \( d_2 \gamma = d_2 \Delta_\gamma^{-1} A \) is the fractional differential introduced in [37] and can be computed using Eq (14).

If we denote by \( \ast \) the usual Hodge Laplacian associated with a product metric \( ds^2 = ds_1^2 + ds_2^2 \), it is a straightforward matter to show that

\[
D_\gamma := \ast D_\gamma \ast
\]

is an operator that takes a \( p \)-form to a \( (p-1) \)-form and it is the (formal) adjoint of \( D_\gamma \) with respect to the standard scalar product on forms. We can show

\[\text{Theorem III.1.} \quad \text{For any } p-\text{form } A = A_i dx^i \text{ we have}
\]

\[
(D_\gamma^* D_\gamma + D_\gamma D_\gamma^*) A = (\Delta_\gamma A_i) dx^i + (\Delta_\gamma^* A_i) dx^i
\]

and in Lorentzian signature

\[
(D_\gamma^* D_\gamma + D_\gamma D_\gamma^*) A = (\Delta_\gamma A_i) dx^i - (\Delta_\gamma^* A_i) dx^i
\]

In particular if we start with the mixed form \( A = A_0 dt + A_{ij} dx^i \wedge dx^j \),

\[
(D_\gamma^* D_\gamma + D_\gamma D_\gamma^*) A = (\partial_0 A_0 - \Delta_\gamma A_0) dt + (\partial_0 A_{ij} - \Delta_\gamma^* A_{ij}) dx^i \wedge dx^j
\]

We now define a non-local \( U(1) \)-Gauge theory for a multi-form \( \Omega \)

\[
D_\gamma \left( \ast D_\gamma \Omega \right) = \ast J,
\]

where \( J \) is a mixed-form. We will specialize to the case that \( \Omega = A_0 dt + A_{ij} dx^i \wedge dx^j \) and then \( J \) will be the form dual to the current (\( d + 1 \))-vector \( (\rho, J^i) \).

Equation (27) is readily seen, after determining the Gauge fixing condition \( D_\gamma \Omega = 0 \), to be equivalent to

\[
(D_\gamma^* D_\gamma + D_\gamma D_\gamma^*) \Omega = \ast J.
\]

Writing as usual \( A_{ij} \) for the vector corresponding to the spatial components of \( A \), Eq. (27) is thus seen to be equivalent to

\[
\left( \frac{\partial^2}{\partial t^2} - \Delta_\gamma \right) A_0 = \rho
\]

\[
\left( \frac{\partial^2}{\partial t^2} - \Delta_\gamma \right) A_{ij} = \dot{J}^i
\]

the non-Lorentzian equations of motion for the conserved currents.

The action of the gauge group that yields such currents is easy to express in the case that \( A \) is a Lie-valued 1-form. We briefly described this without proofs since it follows from a simple generalization of what the authors did in [37]. We describe it in the \( U(1) \)-case only. First, we note that the \( U(1) \)-action is determined by a diagonal action on a multi-form \( \Omega = A_0 \times A_1 \) (here \( A_0 \) and \( A_1 \) are both 1-forms, so the decomposition is only meant to evoke the decomposition \( M = M_1 \times M_2 \)), meaning that given an element \( e^{iA} \in U(1) \), it will act on the individual components of \( \Omega \) separately. We establish the following fact about our \( U(1) \)-Gauge action, denoting by \( \Box_{(s_1, s_2)} := \Delta_\gamma^{s_1} - \Delta_\gamma^{s_2} \) and in fact, as we argued, the most significant case is when \( s_1 = 1 \) and \( s_2 \) is arbitrary (as we can always reduce ourselves to this up to fields redefinitions). In what follows, we then write \( \Box_s \) for \( \Box_{s_s} \).

\[\text{Theorem III.2.} \quad \text{We define an action of } U(1) \text{ on local sections of the principal bundle corresponding to } A \text{ as}
\]

\[
e^{i\Lambda} \Box_{\Box_{(s_1, s_2)}} \left( e^{i\Box_{(s_1, s_2)}} \phi \right).
\]

and we define the non-Lorentz invariant covariant derivative as

\[
\nabla \gamma A \phi = (d + i\Box_{s_s}^\gamma A) \Box_{s_s} \phi.
\]
The corresponding curvature will be
\[ F_{\gamma A} = (d + \Box^{-1} A) D_{\gamma A}. \]  
(33)

Then the equivariance condition
\[ D_{\gamma A} (\omega \Phi \Theta) = e^{\frac{1}{2} \Box^{-1} \Lambda} D_{\alpha \beta A + \gamma A} \Phi \]  
(34)
holds.

The proof here is a straightforward generalization of the equivariance condition presented in Sec. 4 of [45]. For the more general case of a multiform \( \Omega \) which is not comprised of 1-forms, it is easy to write the infinitesimal action of the Gauge group. In case \( \Omega = A_0 dt + A_i dx^i \wedge dx^j \) the infinitesimal action is given by
\[ A_0 \rightarrow A_0 + \frac{\partial \Lambda}{\partial t} \quad A_{ij} \rightarrow A_{ij} - \partial_i \partial_j \Lambda \]  
(35)
Writing the global (not infinitesimal) action in general is more complicated. One difficulty we mention is the fact that if \( \Omega \) is even just a \( p \)-form with \( p \neq 1 \), there is no construction of a \( G \)-principal bundle of which \( \Omega \) is the connection (or no covariant derivative obviously associated with it). We leave this for later considerations.

We now specialize to the context where \( \Omega \) is in fact a mixed tensor \( \Omega = A_0 dt + A_i dx^i \wedge dx^j \). We then use the transformation
\[ \partial_i \rightarrow \partial_i - A_i \quad \partial_i \partial_j \rightarrow \partial_i \partial_j - (\Delta)^{-\frac{1}{2}} A_{ij} \]  
(36)
and the coupling
\[ \sim \int \left( -\Delta^\frac{1}{2} A_{ij} \right) f^{ij} = \int A_{ij} (\Delta)^{-\frac{1}{2}} f^{ij} \]  
(37)
having integrated by parts so that \( A_{ij} \) couples with \( (\Delta)^{\frac{1}{2}} f^{ij} \). By Noether’s first theorem
\[ \partial_i \rho + \partial_i \partial_j \left( -\Delta^\frac{1}{2} \right) f^{ij} = 0, \]  
(38)
meaning the "current" is
\[ f^i = \partial_i \left( -\Delta^\frac{1}{2} f^{ij} \right). \]  
(39)
Given that no equation for the current of the form
\[ J_{ij} = f(\rho) \delta_{ij} \]  
(40)
is valid as it is inconsistent[37, 38] with \( U(1) \) symmetry, the next term is
\[ J_{ij} = \Box \partial_i \partial_j \rho \]  
(41)
oequivalently
\[ (-\Delta)^{\frac{1}{2}} J_{ij} = \Box \partial_i \partial_j (\Delta)^{\frac{1}{2}} \rho. \]  
(42)
Eq.(41) is a direct generalization of the standard Fick’s law. From this we infer
\[ \partial_i \rho + \Box \Delta^\gamma \rho = 0 \]  
(43)
and therefore we find the associated diffusive mode,
\[ \omega = -i \Box k^2 \gamma, \]  
(44)
which for \( \gamma = 1 \) reduces to the standard diffusion equation corresponding to the conservation of the total charge \( Q \) associated to the standard \( U(1) \) invariance. We see then that Nöther’s Second Theorem entails a wide variety of modified diffusive behaviour indicative of anomalous diffusion [8–10].

IV. CONSERVED CHARGES AND GOLDSTONE EFFECTIVE ACTION

Given the most general Lorentz violating Gauge principle, we can now investigate which are the corresponding conserved charges and the effective action for the Goldstone massless modes. Let us start with the example of subdiffusive dynamics
\[ \langle x^2 \rangle \sim B t^{3/2}, \]  
(45)
which corresponds to the anomalous diffusive mode \( \omega = -i \Box k^3 \). This dynamics stems from the higher-order constitutive relation
\[ J^i = \partial_j J^{ij}, \quad J_{ij} = B \partial_i \partial_j \rho \]  
(46)
where \( J^i \) is the spatial current and \( \rho \) the charge density. It is simple to see that this modified constitutive relation follows from the conservation of the electric dipole,
\[ p = \int d^3 x \ x \rho(x,t). \]  
(47)
Moreover, it can be derived by gauging the following scalar effective action
\[ L = c_1 (\partial_i \phi)^2 - c_2 (\partial_i \partial_j \phi)^2 - c_3 (\nabla^2 \phi)^2 + \ldots \]  
(48)
where terms \( (\partial_i \phi)^2 \) are absent because they do not conserve the dipole (47). We gauge the action (48) by introducing the covariant derivatives
\[ \partial_i \rightarrow \partial_i - A_i \quad \partial_i \partial_j \rightarrow \partial_i \partial_j - \partial_i A_{ij} \]  
(49)
The tensorial current we just discussed comes directly from the minimal coupling with the gauge field, \( \sim A_{ij} J^{ij} \). Notice that the conservation of the dipole implies that the dynamics of the emergent quasiparticles is confined along a subspace, in this case a line.

Borrowing from this simple example, we want to find now the general conserved charges and effective actions arising from the non-Lorentz invariant gauge symmetry defined in the previous section. Let us consider a field theory in which the generalized momentum of order \( (\gamma - 1) \) of a certain "charge" distribution \( \rho(t,x) \) is a conserved quantity,
\[ \frac{\partial}{\partial t} m^{(r)} = \frac{\partial}{\partial t} \int \sum_i a_i x_i^{r-1} \rho(t,x) dx = 0, \]  
(50)
where we remark that if \( f(x) \) is a function of the sole variable \( x \), then \((-\Delta)^\gamma f(x) = (-\Delta_x)^\gamma f(x) \) where \((-\Delta_x)^\gamma \) is the (fractional) Laplacian in the variable \( x \). If \((\gamma - 1)\) is an integer, then, \( m^{\gamma_n} \) are the standard momenta, e.g. \( \gamma = 1 \) corresponds to total charge \( Q \), \( \gamma = 2 \) dipole \( p \), etc. The continuity equation, giving rise to our anomalous diffusive mode, is simply a mathematical re-statement of the principle of conservation in Eq. (50). More precisely, the conservation of \( m^{\gamma_n} \) can be re-written in differential form as the anomalous continuity equation,

\[
\partial_t \rho + \Delta x \rho = 0.
\]  

(51)

In the same way, the effective action for the low-energy degrees of freedom takes the following form,

\[
L = D_x \left( \sqrt{D_x} \phi \right) + \ldots
\]  

(52)

and it represents a formal generalization of the example shown in Eq. (48).

V. CONCLUSIONS

It was the purpose of this paper to put under a single umbrella the myriad of diffusive-like equations that have proliferated recently [51, 52] and in the past [8, 20–23, 32–34] to describe anomalous diffusion. What we have shown is that NST makes possible a myriad of diffusive-like equations of motion that only reduce to the traditional diffusive limit in special cases. The source of this multiplicity is the high degeneracy of the eigenvalues of Eq. (9) which generate a hierarchy of conserved charges. At play here is the fact that Fick’s law is not at all general. Our work applies equally to Fourier’s law for heat transport for which exceptions are well catalogued [26]. The key to this generalization is the non-Lorentzian formulation of the gauge symmetries and hence this work completes the fractional formulation of gauge theories we started previously [37, 38, 45].

As a result of the work of Caffarelli and Silvestre [53] who have shown that second-order elliptic differential equations in the upper half-plane in \( \mathbb{R}^{n+1}_+ \) reduce to one with the fractional Laplacian, \((-\Delta)^\gamma \) at \( \mathbb{R}^n \), where a Dirichlet boundary condition is imposed, our work here has demonstrated that anomalous diffusion can be thought of as a problem in which collective excitations arise in a lower-dimensional subspace. While it has been noticed that models requiring higher-rank \( U(1) \) gauge theories [41, 54–56] lead to restricted particle motion in lower dimensional subspaces, the connection to fractional diffusive equations has not been made. The work presented here suggests that for modes with dispersions (ripplons at superfluid interfaces[48, 49]) of the form

\[
\omega = -i D k^{2\gamma},
\]

(53)
a deep connection exists between the parameter \( \gamma \) and the dimensionality of the space for the confined motion in which the effective action is inherently non-local.

APPENDIX: PROOF OF THEOREM III.1

Proof. The proof is a simple generalization of the standard fact that holds for the normal Laplacian on forms. For simplicity (and without loss of generality) we may assume that $M_1 = \mathbb{R}^n$ and $M_2 = \mathbb{R}^{d-n}$ with Euclidean metrics. We then calculate

$$D_p A = \sum_{j_k \in \{1, \ldots, d\}} \frac{\partial}{\partial x^{j_k}} A_{i_1, \ldots, i_p} dx^{j_k} \wedge \cdots \wedge dx^{i_p} + \sum_{j_k \in \{n+1, \ldots, d\}} \frac{\partial}{\partial x^{j_k}} ( \Delta_2^{n+1} A_{i_1, \ldots, i_p} ) dx^{j_k} \wedge \cdots \wedge dx^{i_p} \quad (54)$$

whence

$$\star D_p A = \sum_{j_k \in \{1, \ldots, n\}} (-1)^{p+k-1} \frac{\partial}{\partial x^{j_k}} A_{i_1, \ldots, i_p} dx^{j_k} \wedge \cdots \wedge dx^{i_k} \wedge \cdots \wedge dx^{i_p} + \sum_{j_k \in \{n+1, \ldots, d\}} (-1)^{p+k-1} \frac{\partial}{\partial x^{j_k}} ( \Delta_2^{n+1} A_{i_1, \ldots, i_p} ) dx^{j_k} \wedge \cdots \wedge dx^{i_k} \wedge \cdots \wedge dx^{i_p} \quad (55)$$

which yields

$$D_q \star D_p A = \sum_{j_k \in \{1, \ldots, n\}} (-1)^{p+k-1} \frac{\partial^2}{(\partial x^{j_k})^2} A_{i_1, \ldots, i_p} dx^{j_k} \wedge \cdots \wedge dx^{i_k} \wedge \cdots \wedge dx^{i_p} + \sum_{j_k \in \{n+1, \ldots, d\}} (-1)^{p+k-1} \frac{\partial^2}{(\partial x^{j_k})^2} ( \Delta_2^{n+1} A_{i_1, \ldots, i_p} ) dx^{j_k} \wedge \cdots \wedge dx^{i_k} \wedge \cdots \wedge dx^{i_p} \quad (56)$$

and also

$$\star D_q \star D_p A = \sum_{j_k \in \{1, \ldots, n\}} (-1)^{p+d-p} \frac{\partial^2}{(\partial x^{j_k})^2} A_{i_1, \ldots, i_p} dx^{j_k} \wedge \cdots \wedge dx^{i_p} + \sum_{j_k \in \{n+1, \ldots, d\}} (-1)^{p+d-p} \frac{\partial^2}{(\partial x^{j_k})^2} ( \Delta_2^{n+1} A_{i_1, \ldots, i_p} ) dx^{j_k} \wedge \cdots \wedge dx^{i_k} \wedge \cdots \wedge dx^{i_p} \quad (57)$$
A similar calculation shows that

\[
D_\gamma \star D_\gamma \star A = \\
\sum_{j_k \in \{1, \ldots, n\}} \sum_{k=1}^{d-p} (-1)^{p(d-p)+d-p+\ell-1} \frac{\partial^2}{(\partial x^j)^2} A_{i_{k}, \ldots, j} \, dx^{j_1} \wedge \cdots \wedge dx^{j_p} + \\
\sum_{j_k \in \{n+1, \ldots, d-n\}} \sum_{k=1}^{d-p} (-1)^{p(d-p)+d-p+\ell-1} \frac{\partial^2}{(\partial x^j)^2} (\Delta_{2}^{-1} A_{i_{k}, \ldots, j}) \, dx^{j_1} \wedge \cdots \wedge dx^{j_p} + \\
\sum_{j_k \in \{n+1, \ldots, d-n\}} \sum_{k=1}^{d-p} (-1)^{p(d-p)+d-p+\ell-1} \frac{\partial^2}{(\partial x^j)^2} (\Delta_{2}^{-1} A_{i_{k}, \ldots, j}) \, dx^{j_1} \wedge \cdots \wedge dx^{j_p} 
\]

and therefore

\[
(D_\gamma^\ast D_\gamma + D_\gamma D_\gamma^\ast) A = (\Delta_1^{-1} A_I) d^I - (\Delta_2^{-1} A_I) d^I 
\]

as we wanted to prove.

\[\square\]
