SYMPLECTIC GEOMETRY OF A MODULI SPACE OF FRAMED HIGGS BUNDLES

INDRANIL BISWAS, MARINA LOGARES, AND ANA PEÓN-NIETO

ABSTRACT. Let $X$ be a compact Riemann surface and $D$ an effective divisor on $X$. Let $\mathcal{N}_H(r,d)$ denote the moduli space of $D$-twisted stable Higgs bundles (a special class of Hitchin pairs) on $X$ of rank $r$ and degree $d$. It is known that $\mathcal{N}_H(r,d)$ has a natural holomorphic Poisson structure which is in fact symplectic if and only if $D$ is the zero divisor. We prove that $\mathcal{N}_H(r,d)$ admits a natural enhancement to a holomorphic symplectic manifold which is called $\mathcal{M}_H(r,d)$. This $\mathcal{M}_H(r,d)$ is constructed by trivializing, over $D$, the restriction of the vector bundles underlying the $D$-twisted Higgs bundles; such objects are called framed Higgs bundles. We also investigate the symplectic structure on the moduli space $\mathcal{M}_H(r,d)$ of framed Higgs bundles and also the Hitchin system associated to it.

1. Introduction

Since their inception in [Hi], Hitchin systems have been a rich source of examples of algebraically completely integrable systems. In [Hi], Hitchin proved that the moduli space of Higgs bundles on a compact Riemann surface is a holomorphic symplectic variety which admits an algebraically completely integrable structure provided by what is known as the Hitchin fibration. The symplectic structure of the moduli space arises from the natural Liouville symplectic structure on the total space of the cotangent bundle of the moduli space of vector bundles; this cotangent bundle is in fact a Zariski open dense subset of the moduli space of Higgs bundles.

Let $X$ be a compact connected Riemann surface. Fix an effective divisor $D$ on $X$. A Hitchin pair, or more precisely a $D$-twisted Higgs bundle, on $X$ is a pair $(E, \theta)$, where $E$ is a holomorphic vector bundle on $X$ and $\theta$ is a holomorphic section of the vector bundle $\text{End}(E) \otimes K_X \otimes \mathcal{O}_X(D)$ with $K_X$ being the holomorphic cotangent bundle of $X$. Let $\mathcal{N}_H(r,d)$ be the moduli space of stable $D$-twisted Higgs bundles on $X$ of rank $r$ and degree $d$. It is known that $\mathcal{N}_H(r,d)$ carries a natural holomorphic Poisson structure [Bo], [Mak]. This Poisson structure coincides with the symplectic structure on the moduli space of stable Higgs bundles of rank $r$ and degree $d$ (constructed in [Hi]) when $D$ is the zero divisor. It is also known that this Poisson structure is not symplectic when the divisor $D$ is nonzero.

Given a holomorphic vector bundle $E$ on $X$ of rank $r$, a framing of $E$ over $D$ is a trivialization of the vector bundle $E|_D$ over $D$, meaning a holomorphic isomorphism $\delta$ of

\[ 2010 \text{ Mathematics Subject Classification.} \quad 14D20, 14H60, 53D05. \]

\[ \text{Key words and phrases.} \quad \text{Framed Higgs bundle, holomorphic symplectic form, Poisson map, Hitchin pair, deformation.} \]
A framed bundle is a holomorphic vector bundle equipped with a framing. A framed Higgs bundle is a triple \((E, \delta, \theta)\), where \((E, \delta)\) is a framed bundle and \(\theta\) is a holomorphic section of \(\text{End}(E) \otimes K_X \otimes \mathcal{O}_X(D)\). Let \(\mathcal{M}_H(r, d)\) be the moduli space of semistable framed Higgs bundles on \(X\) of rank \(r\) and degree \(d\). It is known that \(\mathcal{M}_H(r, d)\) is a smooth quasiprojective variety defined over \(\mathbb{C}\) \([\text{Si1, Si2}]\).

We investigate the local structure of \(\mathcal{M}_H(r, d)\). The tangent space to \(\mathcal{M}_H(r, d)\) at a point \((E, \delta, \theta)\) is given by the first hypercohomology of the complex

\[
\mathcal{C}_\ast : \mathcal{C}_0 = \text{End}(E) \otimes \mathcal{O}_X(-D) \xrightarrow{f_\theta} \mathcal{C}_1 = \text{End}(E) \otimes K_X \otimes \mathcal{O}_X(D),
\]

where \(f_\theta(s) = \theta \circ s - s \circ \theta\) (see Corollary 2.8).

It turns out that \(\mathcal{M}_H(r, d)\) has a holomorphic symplectic structure, and moreover the symplectic form is exact (Theorem 3.4). We prove that the forgetful map from the stable locus \(\mathcal{M}_s(r, d)\) of \(\mathcal{M}_H(r, d)\) to \(\mathcal{N}_H(r, d)\),

\[
(E, \delta, \theta) \mapsto (E, \theta),
\]

is compatible with the Poisson structures on \(\mathcal{M}_s(r, d)\) and \(\mathcal{N}_H(r, d)\) (see Theorem 4.1). This means that the pullback, by this forgetful map, of the Poisson bracket \(\{f, g\}\) of two locally defined holomorphic functions \(f\) and \(g\) on \(\mathcal{N}_H(r, d)\) coincides with the Poisson bracket of the pullbacks of \(f\) and \(g\).

We finally study the complete integrability properties of the Hitchin system \(h\) on \(\mathcal{M}_H(r, d)\) with respect to that of \(\mathcal{N}_H(r, d)\) (denoted by \(\widetilde{h}\)) when \(D\) is reduced. The generic fibers of \(h\) are torsors over Jacobian varieties of spectral curves (cf. Proposition 5.4). The largest abelianizable subsystem in turn only admits a Poisson structure. The fibers of the latter system are semiabelian varieties (Proposition 5.11), corresponding to a (local) completion of the Hitchin system of \(\mathcal{M}_H(r, d)\) (Proposition 5.12) which is done transversal to \(\widetilde{h}\).

2. Framed Higgs bundles and their deformations

2.1. Framed Higgs bundles and their moduli spaces. Let \(X\) be a compact connected Riemann surface. The genus of \(X\) will be denoted by \(g_X\). Let \(K_X\) denote the holomorphic cotangent bundle of \(X\). Fix a nonzero effective divisor

\[
D = \sum_{i=1}^{s} n_i x_i,
\]

where \(\{x_i\}_{i=1}^{s}\) are distinct points of \(X\) with \(n_i > 0\) for all \(i\), and \(s \geq 1\).

We will identify \(D\) with the subscheme of \(X\) with structure sheaf \(\mathcal{O}_D = \mathcal{O}_X/\mathcal{O}_X(-D)\). Similarly, for any coherent analytic sheaf \(F\) on \(X\), its restriction to \(D\) will be denoted by \(F_D\).

We will identify a holomorphic vector bundle with the coherent analytic sheaf given by its local holomorphic sections. In particular, for a holomorphic vector bundle \(F\) on \(X\),
the above restriction \( F_D \) will also mean the restriction of the holomorphic vector bundle \( F \) to \( D \). For any vector bundle \( F \) on \( X \), its slope is defined by
\[
\mu(F) := \frac{\deg(F)}{\rk(F)} \in \mathbb{Q}.
\]

**Definition 2.1.** Let \( E \) be a holomorphic vector bundle on \( X \) of rank \( r \). A *frame* on \( E \) is an isomorphism of \( \mathcal{O}_D \) modules
\[
\delta : \mathcal{O}_D^r \rightarrow E_D.
\]
A vector bundle with a frame will be called a *framed bundle*.

**Definition 2.2.** A *Higgs field* on a framed bundle \((E, \delta)\) is a holomorphic section of the vector bundle \( \text{End}(E) \otimes K_X \otimes \mathcal{O}_X(D) \). A framed Higgs bundle is a triple \((E, \delta, \theta)\), where \((E, \delta)\) is a framed bundle and \( \theta \) is a Higgs field on \((E, \delta)\).

A framed bundle \((E, \delta)\) will be called *stable* (respectively, *semistable*) if the underlying vector bundle \( E \) is stable (respectively, semistable). A framed Higgs bundle \((E, \delta, \theta)\) will be called *stable* (respectively, *semistable*) if for every subbundle \( 0 \neq F \subset E \) with \( \theta(F) \subset F \otimes K_X \otimes \mathcal{O}_X(D) \), the inequality
\[
\mu(F) < \mu(E) \quad \text{(respectively, } \mu(F) \leq \mu(E))
\]
holds.

Simpson showed that the semistable framed bundles (respectively, semistable framed Higgs bundles) of rank \( r \) and degree \( d \) have a fine moduli space denoted by \( \mathcal{M}(r, d) \) (respectively, \( \mathcal{M}_H(r, d) \)), which is a smooth quasiprojective irreducible variety \cite{Si1, Si2}.

We will now see that all semistable framed Higgs bundles are simple. The frame thus provides a rigidification of the moduli problem.

**Lemma 2.3.** Let \((E, \theta)\) and \((E', \theta')\) be semistable Higgs bundles on \( X \) with
\[
\mu(E) = \mu(E').
\]
Let \( h : E \rightarrow E' \) be a homomorphism such that
\begin{itemize}
  \item \( \theta' \circ h = (h \otimes 1_{K_X(D)}) \circ \theta \) as homomorphisms from \( E \) to \( E' \otimes K_X(D) \), and
  \item there is a point \( x_0 \in X \) such that \( h(x_0) = 0 \).
\end{itemize}
Then \( h \) vanishes identically.

**Proof.** Assume that \( h \) is not identically zero. Let \( I \) denote the image of \( h \); note that \( I \) is torsion-free because it is a subsheaf of \( E' \). Since \((E, \theta)\) and \((E', \theta')\) are semistable, we have
\[
\mu(E) \geq \mu(I) \geq \mu(E'),
\]
so from (2.2) it follows that \( \mu(I) = \mu(E') \). Now, let \( I' \) be the subbundle of \( E' \) generated by \( I \); this means that \( I' \subset E' \) is the inverse image, under the quotient map \( E' \rightarrow E'/I \), of the torsion part of \( E'/I \). Then
\[
\mu(I') \leq \mu(E') = \mu(I).
\]
Since $\mu(I') = \mu(I)$, it follows that $\deg(I') = \deg(I)$, because $\text{rank}(I') = \text{rank}(I)$. Hence we have $I' = I$. But this is a contradiction, because $h(x_0) = 0$ and $I \neq 0$ implying that $x_0$ lies in the support of $I'/I$. Therefore, we conclude that $h = 0$. \qed

An isomorphism between framed Higgs bundles $(E, \delta, \theta)$ and $(E', \delta', \theta')$ is a holomorphic isomorphism $h : E \to E'$ of vector bundles such that

- $h \circ \delta = \delta'$, and
- $\theta' \circ h = (h \otimes \text{Id}_{K_X(D)}) \circ \theta$.

**Corollary 2.4.** A semistable framed Higgs bundle $(E, \delta, \theta)$ does not admit any nontrivial automorphism.

**Proof.** For any automorphism $h$ of $(E, \delta, \theta)$, consider $h - \text{Id}_E$. It vanishes on $D$. Since the effective divisor $D$ is nonzero, from Lemma 2.3 it follows that $h - \text{Id}_E = 0$. \qed

2.2. **Infinitesimal deformations.** For a coherent analytic sheaf $F$ on $X$, the tensor products $F \otimes_{O_X} \mathcal{O}_X(-D)$ and $F \otimes_{O_X} \mathcal{O}_X(D)$ will be denoted by $F(-D)$ and $F(D)$ respectively.

Let $X(\epsilon) := X \times \text{Spec}(\mathbb{C}[\epsilon]/\epsilon^2)$. An infinitesimal deformation of a framed bundle $(E, \delta)$ (respectively, framed Higgs bundle $(E, \delta, \theta)$) is given by an isomorphism class of a pair $(E_\epsilon, \delta_\epsilon)$ (respectively, triple $(E_\epsilon, \delta_\epsilon, \theta_\epsilon)$) such that

- $E_\epsilon \to X(\epsilon)$ is a holomorphic vector bundle,
- $\delta_\epsilon : \mathcal{O}_{D \times \text{Spec}(\mathbb{C}[\epsilon]/\epsilon^2)} \to E_\epsilon|_{D \times \text{Spec}(\mathbb{C}[\epsilon]/\epsilon^2)}$ is an isomorphism,
- (in case of framed Higgs bundles) $\theta_\epsilon \in H^0(X(\epsilon), \text{End}(E_\epsilon) \otimes q_0^* K_X(D))$, where $q_0$ is the natural projection of $X(\epsilon)$ to $X$,
- $(E_\epsilon, \delta_\epsilon)|_{X \times \{0\}} \cong (E, \delta)$ (respectively, $(E_\epsilon, \delta_\epsilon, \theta_\epsilon)|_{X \times \{0\}} \cong (E, \delta, \theta)$), where $0 \in \text{Spec}(\mathbb{C}[\epsilon]/\epsilon^2)$ denotes the closed point.

**Lemma 2.5.** The space of all infinitesimal deformations of a framed bundle $(E, \delta)$ is identified with $H^1(X, \text{End}(E)(-D))$.

**Proof.** Recall that the space of all infinitesimal deformations of $E$ is $H^1(X, \text{End}(E))$. Now, deformations of $(E, \delta)$ are deformations of $E$ together with the framing. Take a covering of $X$ by affine open subsets $\{U_j\}_{j=1}^d$. A 1-cocycle $\{s_{j,k}\}_{j,k=1}^d$ of $\text{End}(E)$ gives an infinitesimal deformation of $E$ via the vector bundle $E_\epsilon$ on $X(\epsilon)$ defined by the transition functions $\text{Id} + \epsilon \cdot s_{j,k}$ for the local trivializations $(q_0^* E)|_{U_j \times \text{Spec}(\mathbb{C}[\epsilon]/\epsilon^2)}$ over $U_j \times \text{Spec}(\mathbb{C}[\epsilon]/\epsilon^2)$. Clearly, these preserve a frame if and only if $s_{j,k}$ are sections of $\text{End}(E)(-D)$. Next note that a 1-coboundary for $\text{End}(E)(-D)$ gives a trivial infinitesimal deformation of the framed bundle $(E, \delta)$, as it is a trivial deformation of $E$ which preserves the framing. Now the lemma is straight-forward. \qed

Given a framed Higgs bundle $(E, \delta, \theta)$ on $X$, consider the following complex:

$$
\mathcal{C}_1 : \mathcal{C}_0 = \text{End}(E)(-D) \xrightarrow{f_\theta} \mathcal{C}_1 = \text{End}(E) \otimes K_X(D) \xrightarrow{\theta \circ s - s \circ \theta} \mathcal{C}_0
$$
It may be noted that \( f_\theta(\text{End}(E)(-D)) \subset \text{End}(E) \otimes K_X \subset \text{End}(E) \otimes K_X(D) \).

**Lemma 2.6.** The infinitesimal deformations of a framed Higgs bundle \((E, \delta, \theta)\) are parametrized by the first hypercohomology \( H^1(C_\bullet) \) of the complex \( C_\bullet \) in (2.3).

**Proof.** Its proof is very similar to the proof of [BR, Theorem 2.3] (also given in [Bo, Mak]).

Proceeding as in the proof of [BR, Theorem 2.3], we check that if \( \{ U_j := \text{Spec}(A_j) \}_{j=1}^d \) is an affine open covering of \( X \) such that

- each point of \( \{ x_i \}_{i=1}^n \) lies in exactly one of these open subsets \( \{ U_j \}_{j=1}^d \), and
- \( E|_{U_j} \cong \mathcal{O}_{U_j}^r \) for every \( j \),

then \( \{ U_j(\epsilon) := U_j \times \text{Spec}(\mathbb{C}[\epsilon]/\epsilon^2) \}_{j=1}^d \) is an affine open covering of \( X(\epsilon) \) satisfying similar conditions. From Lemma 2.5 we know that the isomorphism class of \( E_\epsilon \) is determined by the element of \( H^1(U_j, \text{End}(E) \otimes K_X(D)|_{U_j}) \) defined by a 1-cocycle \( \eta_{jk} \). The Higgs field \( \theta_\epsilon \) is then given by \( \theta + \gamma_j \epsilon \) on \( U_j(\epsilon) \), where

\[
\gamma_j \in H^0(U_j, \text{End}(E) \otimes K_X(D)|_{U_j}).
\]

The compatibility condition for \( \eta_{jk} \) and \( \gamma_j \) coincides with the condition that \( (\eta_{jk}, \gamma_j) \) defines an element of \( H^1(C_\bullet) \); see [BR, Theorem 2.3], [Bi, Theorem 2.5] for details. \( \square \)

The dual of the complex \( C_\bullet \) in (2.3) is the complex of coherent sheaves on \( X \)

\[
C^\bullet : C^0 := (\text{End}(E) \otimes K_X(D))^* \otimes K_X \xrightarrow{(f_\theta)^* \otimes \text{Id}_{K_X}} C^1 := \text{End}(E)(-D)^* \otimes K_X \quad (2.4)
\]

Since \( \text{End}(E) = \text{End}(E)^* \), we have the following:

**Lemma 2.7.** There is an isomorphism of complexes

\[
C_\bullet \cong C^\bullet \quad (2.5)
\]

given by the commutative diagram

\[
\begin{array}{ccc}
\text{End}(E)(-D) & \xrightarrow{f_\theta} & \text{End}(E) \otimes K_X(D) \\
\| & & \| \\
(\text{End}(E) \otimes K_X(D))^* \otimes K_X & \xrightarrow{(f_\theta)^* \otimes \text{Id}_{K_X}} & \text{End}(E)(-D)^* \otimes K_X.
\end{array}
\]

**Corollary 2.8.** Let \((E, \delta, \theta) \in \mathcal{M}(r,d)\). Deformations of \((E, \delta, \theta)\) are unobstructed. The tangent space of \( \mathcal{M}_H(r,d) \) at \((E, \delta, \theta)\) is identified with \( H^1(C_\bullet) \).

**Proof.** In view of Lemma 2.6, it suffices to show that there is no obstruction to deformation. From Lemma 2.3 it follows immediately that

\[
H^0(C_\bullet) = 0, \quad (2.6)
\]

where \( C_\bullet \) is the complex in (2.3). Serre duality says that \( H^2(C_\bullet) = H^0(C^\bullet)^* \). Hence using Lemma 2.7 and (2.4) it follows that

\[
H^2(C_\bullet) = 0. \quad (2.7)
\]

Hence there is no obstruction to deformations. \( \square \)
Lemma 2.9. There is a tautological embedding

$$
\iota : T^* \mathcal{M}(r, d) \hookrightarrow \mathcal{M}_H(r, d)
$$

whose image is a Zariski open dense subset.

Proof. From Lemma 2.5 it follows that $T(E, \delta) \mathcal{M}(r, d) = H^1(X, \text{End}(E)(-D))$. Also, we have $H^1(X, \text{End}(E)(-D))^* = H^0(X, \text{End}(E) \otimes K_X(D))$ (Serre duality). Consequently, the total space of the cotangent bundle $T^* \mathcal{M}(r, d)$ embeds into $\mathcal{M}_H(r, d)$; this embedding will be denoted by $\iota$. From openness of the semistability condition, [May, p. 635, Theorem 2.8(B)], it follows that the image of $\iota$ is a Zariski open subset of $\mathcal{M}_H(r, d)$. This also implies that the image of $\iota$ is Zariski dense in $\mathcal{M}_H(r, d)$, because $\mathcal{M}_H(r, d)$ is irreducible. □

The dimension of the moduli space $\mathcal{M}_H(r, d)$ can now be calculated.

Proposition 2.10. Let $n = \sum_{i=1}^s n_i$. The dimension of $\mathcal{M}_H(r, d)$ is $2r^2(g_X + n - 1)$, where $g_X$ as before is the genus of $X$.

Proof. By Corollary 2.8

$$\dim \mathcal{M}_H(r, d) = \dim H^1(\mathcal{C}_\bullet) .$$

Now, by (2.6) and (2.7)

$$H^0(\mathcal{C}_\bullet) = 0 = H^2(\mathcal{C}_\bullet) .$$

Hence we have

$$\dim H^1(\mathcal{C}_\bullet) = -\chi(\mathcal{C}_\bullet) = -\chi(\text{End}(E)(-D)) + \chi(\text{End}(E) \otimes K_X(D)) .$$

By Riemann–Roch, $\chi(\text{End}(E) \otimes K_X(D)) = -\chi(\text{End}(E)(-D)) = r^2(g_X + n - 1)$. Therefore, it follows that $\dim H^1(\mathcal{C}_\bullet) = 2r^2(g_X + n - 1)$.

□

3. Symplectic geometry

3.1. A symplectic form on $\mathcal{M}_H(r, d)$. In this section we construct a symplectic form on $\mathcal{M}_H(r, d)$. In view of Corollary 2.8 we will start by constructing a nondegenerate antisymmetric bilinear form on $H^1(\mathcal{C}_\bullet)$.

The isomorphism of complexes $\mathcal{C}_\bullet \sim \mathcal{C}_\bullet^*$ in (2.5) produces an isomorphism of hypercohomologies

$$B_\theta : H^1(\mathcal{C}_\bullet) \sim H^1(\mathcal{C}_\bullet^*) .$$

On the other hand, Serre duality gives an isomorphism

$$H^1(\mathcal{C}_\bullet^*) \sim H^1(\mathcal{C}_\bullet)^* .$$

We recall the explicit description of Serre duality in this case. First note that in view of the isomorphism in (3.1), the isomorphism in (3.2) is uniquely determined by the corresponding isomorphism

$$H^1(\mathcal{C}_\bullet) \sim H^1(\mathcal{C}_\bullet)^*$$

(3.3)
constructed using (3.1). To construct the isomorphism in (3.3), consider the tensor product of complexes $C_\cdot \otimes C_\cdot$:

$$(C_\cdot \otimes C_\cdot)_0 = \text{End}(E)(-D) \otimes \text{End}(E)(-D) \xrightarrow{(f_\theta \otimes \text{Id}) + (\text{Id} \otimes f_\theta)} (C_\cdot \otimes C_\cdot)_1$$

$$= (\text{End}(E) \otimes K_X(D) \otimes \text{End}(E)(-D)) \oplus (\text{End}(E)(-D) \otimes \text{End}(E) \otimes K_X(D))$$

$$(\text{Id} \otimes f_\theta) - (f_\theta \otimes \text{Id}) (C_\cdot \otimes C_\cdot)_2 = (\text{End}(E) \otimes K_X(D)) \otimes (\text{End}(E) \otimes K_X(D)) .$$

We also have the homomorphism

$$\rho : (\text{End}(E) \otimes K_X(D) \otimes \text{End}(E)(-D)) \oplus (\text{End}(E)(-D) \otimes \text{End}(E) \otimes K_X(D))$$

$$\longrightarrow K_X , \quad (a_1 \otimes b_1) \oplus (a_2 \otimes b_2) \longmapsto \text{Tr}(a_1 \circ b_1 + a_2 \circ b_2) .$$

These give the homomorphism of complexes

$$(C_\cdot \otimes C_\cdot)_0 \longrightarrow (C_\cdot \otimes C_\cdot)_1 \longrightarrow (C_\cdot \otimes C_\cdot)_2$$

$$\downarrow \quad \rho \quad \downarrow \quad 0$$

$$(3.4)$$

Now we have the composition of homomorphisms of hypercohomologies

$$\mathbb{H}^1(C_\cdot) \otimes \mathbb{H}^1(C_\cdot) \longrightarrow \mathbb{H}^2(C_\cdot \otimes C_\cdot) \xrightarrow{\rho'} \mathbb{H}^2(0 \to K_X \to 0) = H^1(X, K_X) = \mathbb{C} , \quad (3.5)$$

where $\rho'$ is given by the homomorphism of complexes in (3.4). Let

$$\Psi_\theta : \mathbb{H}^1(C_\cdot) \otimes \mathbb{H}^1(C_\cdot) \longrightarrow \mathbb{C}$$

be the bilinear form constructed in (3.5).

The earlier mentioned Serre duality in (3.3) is given by the bilinear form $\Psi_\theta$ in (3.6). Note that $\Psi_\theta$ is nondegenerate because the homomorphism in (3.3) is an isomorphism. Also, $\Psi_\theta$ is anti-symmetric by construction.

Therefore, we have the following:

**Proposition 3.1.** There is a nondegenerate holomorphic two form $\Psi$ on $\mathcal{M}_H(r, d)$ whose evaluation at any point $(E, \delta, \theta) \in \mathcal{M}_H(r, d)$ is $\Psi_\theta$ in (3.6).

**Proof.** The above pointwise construction of $\Psi_\theta$ clearly works for families of framed Higgs bundles. \qed

Before exploring $\Psi_\theta$ further, we introduce a one form on $\mathcal{M}_H(r, d)$.
Consider the short exact sequence of complexes of coherent sheaves on $X$

$$\begin{align*}
&D_{\bullet} : 0 \to \text{End}(E) \otimes K_X(D) \to 0 \\
&C_{\bullet} : \text{End}(E)(-D) \to \text{End}(E) \otimes K_X(D) \to 0 \\
&E_{\bullet} : \text{End}(E)(-D) \to 0 \\
&0 \to 0 \to \text{End}(E) \otimes K_X(D) \to 0
\end{align*}$$

In the above diagram, both of the complexes $D_{\bullet}$ and $E_{\bullet}$ have only one nonzero term. Hence their hypercohomologies are just (shifted) cohomologies of the single nonzero term. Thus we have an associated long exact sequence of hypercohomologies

$$0 \to H^0(C_{\bullet}) \to H^0(E_{\bullet}) = H^0(X, \text{End}(E)(-D)) \to H^1(D_{\bullet})$$

$$= H^0(X, \text{End}(E) \otimes K_X(D)) \xrightarrow{a} H^1(C_{\bullet}) \xrightarrow{b} H^0(E_{\bullet}) = H^1(X, \text{End}(E)(-D)) \to H^2(D_{\bullet}) = H^1(X, \text{End}(E) \otimes K_X(D)) \to H^2(E_{\bullet}) \to 0 .$$

The homomorphism $b$ in (3.7) is the forgetful map that sends an infinitesimal deformation of $(E, \delta, \theta)$ to the infinitesimal deformation of $(E, \delta)$ obtained from it by simply forgetting the Higgs field. The homomorphism $a$ in (3.7) is the one that sends a section

$$v \in H^0(X, \text{End}(E) \otimes K_X(D))$$

to the infinitesimal deformation of $(E, \delta, \theta)$ defined by $t \mapsto (E, \delta, \theta + tv)$.

Since $H^0(X, \text{End}(E) \otimes K_X(D)) = H^1(X, \text{End}(E)(-D))^*$ (Serre duality), we have a homomorphism

$$\Phi_\theta : H^1(C_{\bullet}) \to \mathbb{C}, \ v \mapsto \theta(b(v)) ,$$

where $b$ is the homomorphism in (3.7).

The above construction produces the following:

**Proposition 3.2.** There is a holomorphic one-form $\Phi$ on $\mathcal{M}_H(r,d)$ whose evaluation at any point $(E, \delta, \theta) \in \mathcal{M}_H(r,d)$ is $\Phi_\theta$ in (3.8).

**Proof.** The above pointwise construction of $\Phi_\theta$ clearly works for families of framed Higgs bundles. \qed

Using the arguments in [BR, Theorem 4.6] it can be shown that $\Psi_\theta$ defined in (3.6) is the germ at $(E, \delta, \theta)$ of the form $d\Phi$. We hereby give a somewhat simplified proof.
3.2. Relating to the Liouville form. For any complex manifold $N$, the total space $T^*N$ of the holomorphic cotangent bundle of $N$ is equipped with the Liouville holomorphic 1-form, which is denoted by $\eta_N$. The holomorphic 2-form $d\eta_N$ is the Liouville symplectic form on $T^*N$.

Recall from Lemma 2.9 that we have a Zariski dense open subset $\iota : T^*M(r, d) \subset \mathcal{M}_H(r, d)$. In this subsection we will prove that $\iota^*\Phi$ is the Liouville 1-form and $\iota^*\Psi$ is the Liouville symplectic form on the cotangent bundle $T^*M(r, d)$.

**Proposition 3.3.** The Liouville 1-form on $T^*M(r, d)$ coincides with the pullback $\iota^*\Phi$, where $\iota$ is the embedding in (2.8) and $\Phi$ is the one-form in Proposition 3.2.

The pullback $\iota^*\Psi$ is the Liouville symplectic form on $T^*M(r, d)$, meaning $\iota^*\Psi = d\iota^*\Phi$, where $\Psi$ is the two-form in Proposition 3.1.

**Proof.** Let

$$p : T^*M(r, d) \rightarrow \mathcal{M}(r, d)$$

be the natural projection. For any $z := (E, \delta, \theta) \in T^*M(r, d) \subset \mathcal{M}_H(r, d)$, let

$$dp(z) : T_zT^*M(r, d) \rightarrow T_{p(z)}\mathcal{M}(r, d)$$

be the differential of $p$ at $z$. We noted earlier that the homomorphism $b$ in (3.7) is the forgetful map that sends an infinitesimal deformation of $(E, \delta, \theta)$ to the infinitesimal deformation of $(E, \delta)$ obtained from it by simply forgetting the Higgs field. This means that $b$ coincides with the above homomorphism $dp(z)$. Now from the definition of the Liouville 1-form on $T^*M(r, d)$, and the construction of $\Phi_\delta$ in (3.8), it follows immediately that $\iota^*\Phi$ is the Liouville 1-form on $T^*M(r, d)$.

The fact that $\iota^*\Psi = d\iota^*\Phi$ follows from a standard argument (see [BR, Theorem 4.3], [Bi, Proposition 7.3], [Bo, Theorem 4.5.1], [Mak]). We omit the details. $\square$

**Theorem 3.4.** The holomorphic 2-form $\Psi$ on $\mathcal{M}_H(r, d)$ is symplectic. Moreover,

$$\Psi = d\Phi$$

on $\mathcal{M}_H(r, d)$.

**Proof.** We know that $\Psi$ is nondegenerate and antisymmetric. So it suffices to prove that $\Psi = d\Phi$. By Proposition 3.3 the form $\Psi$ coincides with $d\Phi$ on the dense open subset $T^*M(r, d)$ of $\mathcal{M}_H(r, d)$. This implies that $\Psi = d\Phi$ on the entire $\mathcal{M}_H(r, d)$.$\square$

4. Poisson maps

In this section we compare the Poisson structure on $\mathcal{M}_H(r, d)$ with the Poisson structure on the moduli space $N_H(r, d)$ of stable Hitchin pairs.

For any holomorphic symplectic manifold $(M, \omega)$, we may construct a Poisson bracket of any two locally defined holomorphic functions $f, g \in \mathcal{O}_M$, by means of the Hamiltonian vector fields $X_f$ and $X_g$ associated to them, that is,

$$\{f, g\} := X_f g = -X_g f = -\{g, f\};$$
the Hamiltonian vector field $X_h$ for a function $h$ is defined by the equation $dh(v) = \omega(X_h, v)$, where $v$ is any vector field on $M$. The above pairing $\{\cdot, \cdot\}$ provides $\mathfrak{o}_M$ with a Lie algebra structure which satisfies the Leibniz rule which says that $\{f, gh\} = \{f, g\}h + g\{g, h\}$; therefore this pairing produces a Poisson structure on $M$.

Let $(Y_1, \omega_1)$ and $(Y_2, \omega_2)$ be two holomorphic Poisson manifolds, where

$$\omega_1 : T^*Y_1 \longrightarrow TY_1 \quad \text{and} \quad \omega_2 : T^*Y_2 \longrightarrow TY_2$$

are the holomorphic homomorphisms giving the Poisson structures. A holomorphic map $\beta : Y_1 \longrightarrow Y_2$ is said to be compatible with the Poisson structures if

$$\{f, g\} \circ \beta = \{f \circ \beta, g \circ \beta\}$$

for all locally defined holomorphic functions $f, g$ on $Y_2$, where $\{-, -\}_1$ and $\{-, -\}_2$ are the Poisson brackets on $Y_1$ and $Y_2$ respectively.

Let $d\beta : TY_1 \longrightarrow TY_2$ be the differential of the map $\beta$. It is straight-forward to check that the map $\beta$ is compatible with the Poisson structures if and only if

$$d\beta(\omega_1(x)((d\beta)^*(x)(u))) = \omega_2(u)$$

for all $u \in T_yY_2$ and $x \in \beta^{-1}(y)$, where $(d\beta)^*(x) : T^*_yY_2 \longrightarrow T^*_xY_1$ is the dual of the differential $d\beta(x)$ in (4.1). Note that both sides of (4.2) are elements of $T_yY_2$.

Let $N_H(r, d)$ be the moduli space of stable Hitchin pairs $(E, \theta)$, where

- $E$ is a holomorphic vector bundle on $X$ of rank $r$ and degree $d$, and
- $\theta \in H^0(X, \text{End}(E) \otimes K_X(D))$.

The choice of a section $s$ of $O_X(D)$ determines a holomorphic Poisson structure on $N_H(r, d)$ [Bo] (see also [Hi], [La]); we will always take $s$ to be the section given by the constant function $1$. The construction of the Poisson structure is recalled in the proof of Theorem 4.1.

Let $\tilde{\Psi}' : T^*N_H(r, d) \longrightarrow TN_H(r, d)$ be this Poisson structure on $N_H(r, d)$. Let

$$\tilde{\Psi} : T^*M_H(r, d) \longrightarrow TM_H(r, d)$$

be the Poisson structure on $M_H(r, d)$ given by the symplectic form $\Psi$ in Theorem 3.4.

Let $M_H^s(r, d) \subset M_H(r, d)$ be the stable locus; it is a Zariski open dense subset. Let

$$Q : M_H^s(r, d) \longrightarrow N_H(r, d), \quad (E, \delta, \theta) \longmapsto (E, \theta)$$

be the forgetful map that simply forgets the framing.

**Theorem 4.1.** The map $Q$ in (4.5) is compatible with the Poisson structures $\tilde{\Psi}'$ and $\tilde{\Psi}$ on $N_H(r, d)$ and $M_H^s(r, d)$ respectively.
Proof. We will check the criterion in (4.2).

Consider the complex of coherent sheaves on $X$

$$
\mathcal{C}_r^*: \mathcal{C}_r^0 := (\mathrm{End}(E) \otimes K_X(D))^* \otimes K_X \xrightarrow{(f_0)^* \otimes \text{id}_{K_X}} \mathcal{C}_r^1 := \mathrm{End}(E)^* \otimes K_X.
$$

(4.6)

The identity map of $(\mathrm{End}(E) \otimes K_X(D))^* \otimes K_X$ and the natural inclusion of $\mathrm{End}(E)^* \otimes K_X$ in $\mathrm{End}(E)(-D)^* \otimes K_X$ (recall that the divisor $D$ is effective) together produce a homomorphism of complexes

$$
\xi: \mathcal{C}_r^* \longrightarrow \mathcal{C}^*
$$

(the complex $\mathcal{C}$ is constructed in (2.4)); in other words, the commutative diagram

$$
\begin{array}{ccc}
(\mathrm{End}(E) \otimes K_X(D))^* \otimes K_X & \xrightarrow{(f_0)^* \otimes \text{id}_{K_X}} & \mathrm{End}(E)^* \otimes K_X \\
\| & & \downarrow \\
(\mathrm{End}(E) \otimes K_X(D))^* \otimes K_X & \xrightarrow{(f_0)^* \otimes \text{id}_{K_X}} & \mathrm{End}(E)(-D)^* \otimes K_X = \mathrm{End}(E)^* \otimes K_X(D)
\end{array}
$$

defines $\xi$. Let

$$
\xi_*: \mathbb{H}^1(\mathcal{C}_r^*) \longrightarrow \mathbb{H}^1(\mathcal{C}^*)
$$

(4.7)

be the homomorphism of hypercohomologies induced by the above homomorphism $\xi$ of complexes.

We note that $T_{Q(E,\delta,\theta),N_H}(r,d) = T_{(E,\delta,\theta),N_H}(r,d) = \mathbb{H}^1(\mathcal{C}_r^*)$ [Bo], [Mak], [BR]. On the other hand,

$$
\mathbb{H}^1(\mathcal{C}^*) = \mathbb{H}^1(\mathcal{C}_r^*)^* = T_{(E,\delta,\theta),M_H}(r,d)
$$

(Corollary 2.8 and 3.2). Take any

$$
w \in \mathbb{H}^1(\mathcal{C}_r^*) = T_{Q(E,\delta,\theta),N_H}(r,d).
$$

We will show that

$$
(dQ)^*(E,\delta,\theta)(w) = \xi_*(w),
$$

(4.8)

where $\xi_*$ is constructed in (4.7).

To prove (4.8), consider the complex of coherent sheaves on $X$

$$
\mathcal{C}_r^\tau: \mathcal{C}_r^\tau_0 = \mathrm{End}(E) \xrightarrow{f_0} \mathcal{C}_r^\tau_1 = \mathrm{End}(E) \otimes K_X(D).
$$

(4.9)

We have

$$
T_{Q(E,\delta,\theta),N_H}(r,d) = T_{(E,\delta,\theta),N_H}(r,d) = \mathbb{H}^1(\mathcal{C}_r^\tau)
$$

[Bo], [Mak], [BR]. Next we note that the identity map of $\mathrm{End}(E) \otimes K_X(D)$ and the natural inclusion of $\mathrm{End}(E)(-D)$ in $\mathrm{End}(E)$ together produce a homomorphism of complexes

$$
\zeta: \mathcal{C}_s \longrightarrow \mathcal{C}_r^\tau
$$

(\mathcal{C}_s$ is constructed in (2.3)); in other words, we have the commutative diagram

$$
\begin{array}{ccc}
\mathrm{End}(E)(-D) & \xrightarrow{f_0} & \mathrm{End}(E) \otimes K_X(D) \\
\downarrow & & \downarrow \\
\mathrm{End}(E) & \xrightarrow{f_0} & \mathrm{End}(E) \otimes K_X(D)
\end{array}
$$

(4.10)
that defines $\zeta$. Let
\[ \zeta_* : H^1(C_\tau) \to H^1(C^\tau) \] (4.11)
be the homomorphism of hypercohomologies induced by the above homomorphism $\zeta$ of complexes. It can be shown that in terms of the identifications
\[ T_{Q(E,\delta,\theta)}N_H(r,d) = H^1(C_\tau) \text{ and } T_{(E,\delta,\theta)}M^s_H(r,d) = H^1(C_\tau), \]
the differential
\[ dQ(E,\delta,\theta) : T_{(E,\delta,\theta)}M^s_H(r,d) \to T_{Q(E,\delta,\theta)}N_H(r,d) \]
of $dQ$ at $(E,\delta,\theta) \in M^s_H(r,d)$ coincides with the homomorphism $\zeta_*$ constructed in (4.11). Indeed, this follows immediately from the constructions of the map $Q$ and the homomorphism $\zeta_*$. Finally, (4.8) follows from the isomorphism in (3.2) and the definition of the homomorphism $(dQ)^*(E,\delta,\theta)$ as the dual homomorphism.

At this point, we will recall the construction of the Poisson structure $\tilde{\Psi}'$ in (4.3). For this, consider the complexes $C^\tau_\tau$ and $C^\tau_{\tau\tau}$ constructed in (4.6) and (4.9) respectively. We have a homomorphism of complexes
\[ \varpi : C^\tau_{\tau\tau} \to C^\tau_\tau \] (4.12)
defined by the following diagram of homomorphisms:
\[
\begin{array}{ccc}
(\text{End}(E) \otimes K_X(D))^* \otimes K_X &=& \text{End}(E)(-D) \\
\downarrow & & \downarrow \\
\text{End}(E) & \xrightarrow{(f_\theta)^* \otimes \text{Id}_{K_X}} & \text{End}(E) \otimes K_X(D)
\end{array}
\]
note that it is used that
\[ \bullet \text{ End}(E)^* = \text{End}(E), \quad \text{and} \]
\[ \bullet \Theta_X(-D) \text{ and } \Theta_X \text{ are contained in } \Theta_X \text{ and } \Theta_X(D) \text{ respectively.} \]
Let
\[ \varpi_* : H^1(C^\tau_\tau) \to H^1(C^\tau_{\tau\tau}) \] (4.13)
be the homomorphism of hypercohomologies induced by the homomorphism of complexes $\varpi$ in (4.12). Since
\[ H^1(C^\tau_\tau) = T^{s}_{(E,\theta)}N_H(r,d) \text{ and } H^1(C^\tau_{\tau\tau}) = T^{s}_{(E,\theta)}N_H(r,d), \]
the above homomorphism $\varpi_*$ produces a homomorphism
\[ T^s_{(E,\theta)}N_H(r,d) \to T^{s}_{(E,\theta)}N_H(r,d). \]
This homomorphism coincides with $\tilde{\Psi}'(E,\theta)$ in (4.3).

Finally, consider the isomorphism $\tilde{\Psi}$ in (4.4). We note that $\tilde{\Psi}$ coincides with the homomorphism of hypercohomologies induced by the isomorphism of complexes in Lemma 2.7. Using this and (3.3) it follows that the composition
\[ \tilde{\Psi} \circ (dQ)^*(E,\delta,\theta) : T_{Q(E,\delta,\theta)}N_H(r,d) = H^1(C^\tau_\tau) \to H^1(C_\tau) = T_{(E,\delta,\theta)}M^s_H(r,d) \]
coincides with the homomorphism of hypercohomologies associated to the following natural homomorphism of complexes:

\[
\begin{array}{ccc}
(\text{End}(E) \otimes K_X(D))^* \otimes K_X & \overset{(f_\theta)^* \otimes \text{Id}_{K_X}}{\longrightarrow} & \text{End}(E)^* \otimes K_X \\
\| & & \downarrow \\
\text{End}(E)(-D) & \overset{f_\theta}{\longrightarrow} & \text{End}(E) \otimes K_X(D)
\end{array}
\]

(as before, we use that \(\text{End}(E)^* = \text{End}(E)\) and that \(O_X\) is contained in \(O_X(D)\)). From the above description of \(\tilde{\Psi} \circ (dQ)^*(E, \delta, \theta)\), and the earlier observation that \(dQ(E, \delta, \theta)\) coincides with the homomorphism \(\zeta^*\) in (4.11), it follows that the composition

\[
(dQ) \circ \tilde{\Psi} \circ (dQ)^*(E, \delta, \theta) : T_{\mathcal{M}_s^H(r, d)}^\ast N_H(r, d) = H^1(C_\tau^\ast) \longrightarrow H^1(C_\tau^\ast) = T_{Q(E, \delta, \theta)}^\ast N_H(r, d)
\]

(4.14)

coincides with the homomorphism \(\varpi^*\) in (4.13) of hypercohomologies associated to the homomorphism \(\varpi\) of complexes in (4.12). Consequently, the homomorphism in (4.14) coincides with \(\tilde{\Psi}'\) in (4.3). This completes the proof.

□

5. The Hitchin integrable system

Recall that, for any holomorphic symplectic manifold \((M, \omega)\), we denote by \(\{\cdot, \cdot\}\) the associated Poisson bracket on \(\mathcal{O}_M\).
Two functions $f, g \in \mathcal{O}_M$ are said to Poisson commute if
\[ \{f, g\} = 0. \]

An algebraically completely integrable system on $M$ consists of functions $f_1, \ldots, f_d \in \mathcal{O}_M$ with $d = \frac{1}{2} \dim M$, such that

- $\{f_i, f_j\} = 0$ for all $1 \leq i, j \leq d$,
- the corresponding Hamiltonian vector fields $X_{f_1}, \ldots, X_{f_d}$ are linearly independent at the general point, and
- the general fiber of the map $(f_1, \ldots, f_d) : M \rightarrow \mathbb{C}^d$ is an open subset of abelian variety with the vector fields $X_{f_1}, \ldots, X_{f_d}$ on it being linear.

When the number of the Poisson commuting functions satisfying the above three conditions is less than half the dimension of $M$ we call it a complex partially integrable system.

5.1. The Hitchin fibration. The Hitchin fibration for the moduli space of framed Higgs bundles is defined to be the map
\[ h : \mathcal{M}_H(r, d) \rightarrow \mathcal{H} := \bigoplus_{i=1}^r H^0(X, K_X^i(iD)) \] (5.1)
given by the characteristic polynomial of the Higgs field, that is
\[ h(E, \delta, \theta)(x) = \det(k_{1_E|x} - \theta|x) = k^r + a_1(\theta)(x)k^{r-1} + \cdots + a_r(\theta)(x) \]
where $k \in K_X(D)|_x$ and $a_1, \ldots, a_r$ are a conjugation invariant basis of homogeneous polynomial functions on $\mathfrak{gl}(r)$. Equivalently, they are elementary symmetric polynomials on the Cartan subalgebra $\mathbb{C}^r$.

Since $H^1(X, K_X^i(iD)) = 0$, the dimension of the vector space $\mathcal{H}$ is
\[ N := \dim \mathcal{H} = r^2(g_X - 1) + \frac{r(r + 1)}{2}n, \]
by the Riemann-Roch theorem. Hence $h = (h_1, \ldots, h_N)$, where $h_i$ is a polynomial function of degree $i$.

Theorem 5.1. The above functions $h_1, \ldots, h_N$, Poisson commute.

Proof. Denote by $X_{h_i}$ the Hamiltonian vector field associated to the function $h_i$. Recall that $X_{h_i}$ is such that $dh_i = \Psi(X_{h_i}, \cdot)$ and $\{h_i, h_j\} = X_{h_i}h_j$.

First we need to give an explicit description of the functions $h_i$ which are defined by the characteristic polynomial of the Higgs field.

The above coefficients $a_i(\theta)$ are given by elementary symmetric polynomials in the eigenvalues of $\theta$, i.e.,
\[ h(E, \delta, \theta) = p(k) = \sum_{i=0}^N k^{N-i}(-1)^i \text{Tr}(\wedge^i \theta). \]
Moreover, since each $\text{Tr}(\wedge^i\theta)$ can be expressed in terms of the trace of powers of $\theta$, we get that

$$p(k) = \sum_{i=0}^{N} k^{N-i} (-1)^i (\text{Tr}(\theta^i) + Q_i(\text{Tr}(\theta), \ldots, \text{Tr}(\theta^{i-1}))),$$

where $Q_i$ is a polynomial in $i-1$ variables given by what are known as Newton identities.

Therefore, the space of functions $h_i$ is generated by the functions $\text{Tr}(\theta^i)$, and to prove that the functions $h_i$ and $h_j$ Poisson commute it is enough to prove that $\text{Tr}(\theta^i)$, $\text{Tr}(\theta^j)$ do so.

To compute $\{\text{Tr}(\theta^i), \text{Tr}(\theta^j)\}$ we need to compute first the Hamiltonian vector fields generated by them, and in order to do that we need to describe the differential of $\text{Tr}(\theta^i)$.

Take a trivialization $\varphi : K_X(D)|_U \rightarrow \mathcal{O}_U$, we denote by

$$\text{Tr}_i : \mathcal{M}_H(r, d) \rightarrow \mathbb{C}$$

the composition of $(E, \delta, \theta) \mapsto \text{Tr}(\theta^i)$ with $\varphi^\circ i$.

For any $v \in T_{(E, \delta, \theta)}\mathcal{M}_H(r, d)$; we write it as a cocycle $v = (\eta_{ij}, \gamma_j)$ representing an element of $\mathbb{H}^1(\mathcal{C}_*)$. It corresponds to an infinitesimal deformation of $(E, \delta, \theta, \epsilon)$. By the first order expansion of the Taylor series the function $\text{Tr}_i$ may be written as

$$\text{Tr}_i(E, \delta, \theta) = \text{Tr}_i(E, \delta, \theta) + \epsilon \text{Tr}'_i(E, \delta, \theta),$$

where $\text{Tr}'_i(E, \delta, \theta) = \langle d\text{Tr}_i(E, \delta, \theta), v \rangle$ is the derivative of $\text{Tr}_i$ in the direction of $v$ at the point $(E, \delta, \theta)$.

Consequently, we have

$$\text{Tr}_i(E, \delta, \theta) = \varphi^\circ i \circ \text{Tr}(\theta^i) = \varphi^\circ i \circ \text{Tr}((\theta + \epsilon \gamma_j)^i) = \varphi^\circ i \circ (\text{Tr}(\theta^i) + i\epsilon \text{Tr}(\theta^{i-1}\gamma_j))$$

$$= \text{Tr}_i(E, \delta, \theta) + i\epsilon \text{Tr}_{i-1}(E, \delta, \theta)$$

where for the last step we used the properties of the trace.

Therefore, we identify

$$\text{Tr}'_i(E, \delta, \theta) = i\text{Tr}_{i-1}(E, \delta, \theta) = i\text{Tr}(\theta^{i-1}\gamma_j).$$

By setting $d\text{Tr}'_i(E, \delta, \theta) = (\nu_{jk}, \sigma_j)$, we get that

$$i\text{Tr}_{i-1}(E, \delta, \theta) = i\text{Tr}(\theta^{i-1}\gamma_j) = (\nu_{jk}, \sigma_j) = \text{Tr}(\gamma_j \nu_{jk} + \sigma_j \eta_{jk}).$$

Hence we may write $(\nu_{jk}, \sigma_j) = (0, i\theta^{i-1}|_{U_{jk}})$. Indeed, it satisfies the equation

$$\sigma_k - \sigma_j = [i\theta^{i-1}|_{U_{jk}}, \theta] = 0$$

and the equation (5.3). This proved that

$$d\text{Tr}_i(E, \delta, \theta) = (0, i\theta^{i-1}).$$

Finally we have

$$\{\text{Tr}_i, \text{Tr}_j\}(E, \delta, \theta) = \langle \Psi_{\theta}, d\text{Tr}_i \wedge d\text{Tr}_j \rangle|_{(E, \delta, \theta)} = \langle d\text{Tr}_i, B(d\text{Tr}_j) \rangle|_{(E, \delta, \theta)}$$

$$= \langle (0, i\theta^{i-1}), B_\theta(0, j\theta^{j-1}) \rangle = 0.$$
As a corollary we recover the following result due to Bottacin [Bo].

**Corollary 5.2.** Let
\[ \tilde{h} = (\tilde{h}_1, \cdots, \tilde{h}_N) : \mathcal{N}_H(r, d) \rightarrow \mathcal{K} \]  
be the Hitchin map, defined in [Hi], [Bo], [Ni], which sends any pair \((E, \theta)\) to the characteristic polynomial of \(\theta\). Then the functions \(\tilde{h}_i\) Poisson commute.

**Proof.** This follows from Theorem 5.1 and Theorem 4.1 after observing that
\[ \tilde{h}(Q(E, \delta, \theta)) = h(E, \delta, \theta) \]  
for the forgetful map \(Q\) in (4.5).

**Remark 5.3.** Conversely, the above result of Bottacin (namely, Corollary 5.2) and Theorem 4.1 together imply Theorem 5.1.

We next study the fibers of the map \(h\). Henceforth, we will assume the divisor \(D\) to be reduced.

Let \(|K_X(D)|\) denote the total space of the line bundle \(K_X(D)\). This surface admits a natural morphism
\[ \pi : |K_X(D)| \rightarrow X. \]
First, for each \(b = (b_1, \ldots, b_r) \in \mathcal{K}\), we define a divisor \(X_b \subset |K_X(D)|\) called the spectral curve. This is the vanishing locus of the section
\[ \lambda^r + \pi^*b_1\lambda^{r-1} + \cdots + \pi^*b_r \in H^0(|K_X(D)|, \pi^*K_X(D)^{\oplus r}), \]
where \(\lambda \in H^0(|K_X(D)|, \pi^*K_X(D))\) is the tautological section.

**Proposition 5.4.** The generic fiber of \(h\), the Hitchin map for \(\mathcal{M}_H(r, d)\), is a \(\text{GL}(r, \mathbb{C})/\mathbb{C}^\times\) torsor over the Jacobian of the spectral curve \(X_b\). More precisely, the torsor whose fiber over \(L \in \text{Jac}(X_b)\) is
\[ \text{Aut}((\pi_*L)_D)/\mathbb{C}^\times. \]  

**Proof.** Let \(\tilde{h} : \mathcal{N}_H(r, d) \rightarrow \mathcal{K}\) be the Hitchin map for Higgs pairs. The forgetful map \(Q\) defined in (4.5) satisfies that
\[ \tilde{h}(Q(E, \delta, \theta)) = h(E, \delta, \theta). \]
Thus \(Q\) takes fibers to fibers. Now, generically, \(\tilde{h}^{-1}(b)\) is the Jacobian of the spectral curve \(X_b\) [BNR Proposition 3.6]. The proposition now follows from Proposition 4.2. \(\square\)

### 5.2. An integrable subsystem

The Hitchin map in (5.1) satisfies some of the conditions of completely integrable systems. There are two main problems that prevent it from being completely integrable: 1) the fibers are not even abelian groups, to be abelian varieties; 2) the dimension of fibers is too large.

In this section we define a smaller subsystem
\[ h : \mathcal{M}^\Delta_H(r, d) \rightarrow \mathcal{K} \]
whose fibers are semiabelian varieties, and whose dimension is twice the dimension of \(\mathcal{K}\). The price for it is the loss of the symplectic structure, which becomes a Poisson structure.
In order to do this, consider the family of spectral curves parametrized by $H$:

$$X \longrightarrow H.$$  

(5.6)

This is the subscheme of $|K_X(D)| \times H$ consisting of points $(k, b)$ satisfying

$$\lambda^r(k) + \pi^*b_1\lambda^{r-1}(k) + \cdots + \pi^*b_r(k) = 0.$$

Using [BNR, Proposition 3.6], it follows that the generic Hitchin fiber $h^{-1}(b)$ is isomorphic to the Jacobian $\text{Jac}(X_b)$. This isomorphism is called the spectral correspondence.

We can restate the above in terms of relative Jacobians. Consider the relative Jacobian $\text{Jac}_H(X)$, by which we mean stable relative line bundles. Stability is defined so $\text{Jac}_H(X)$ parametrizes, via the spectral correspondence, stable Hitchin pairs. The spectral correspondence gives a morphism

$$s : \text{Jac}_H(X) \longrightarrow N_H(r, d).$$  

(5.7)

Now, let $\widetilde{D} := \pi^*D \subset |K_X(D)|$. We consider relative framed line bundles on $X$, that is, pairs $(L, \delta')$ for $L \in \text{Jac}_H(X)$, such that

$$L_b|_{\widetilde{D}_b} \cong O_{\widetilde{D}_b}^\times,$$

where $X_b := X|_{\{b\}}$, $L_b = L|_{X_b}$ and $\widetilde{D}_b = \widetilde{D} \cap X_b$. We will say that such a framed line bundle $(L, \delta)$ is stable if the underlying line bundle is so, or in other words, if $L$ yields a stable pair under the spectral correspondence.

**Proposition 5.5.** Relative framed line bundles on $X|_{Hnr}$ are parametrized by a $(\mathbb{C}^\times)^{nr-1}$ torsor $P$ over $\text{Jac}_H(X|_{Hnr})$.

**Proof.** The proof that this defines a torsor is very similar to that of Proposition 4.2 and is thus omitted.  

We also get:

**Lemma 5.6.** The spectral correspondence induces a morphism

$$\sigma : P \rightarrow \mathcal{M}_H(r, d).$$  

(5.8)

**Definition 5.7.** The image $\sigma(P) \subset \mathcal{M}_H(r, d)$, under the spectral correspondence, will be called the moduli of diagonally framed Higgs pairs, and it will be denoted by $\mathcal{M}_{\Delta H}(r, d)$.

Next we study the subvariety $\mathcal{M}_{\Delta H}(r, d)$ infinitesimally. Given $(E, \delta, \theta) \in \mathcal{M}_{\Delta H}(r, d)$, we have that over each $x_i \in D$, there are distinguished lines $L^i_j$ such that $\delta \pi^i \delta'$ is diagonal for the identification $E_{x_i} \cong \oplus_j L^i_j$. Let $\pi_j : E_{x_i} \rightarrow L^i_j$ be the projection. Let $\text{Diag}_E \subset \text{End}(E)|_D$ be the subset of endomorphisms which are diagonal in the preferred reference. Let

$$\pi : \text{End}(E) \rightarrow \text{Diag}_E$$

be the morphism associating to $f$ the map

$$\pi(f) : v \mapsto (\pi_1(f(\pi_1(v))), \ldots, \pi_r(f(\pi_r(v))))$$
where \( v \in E_x \).

Consider the complex

\[
\mathcal{C}_\Delta^\bullet : \ker(\pi) \xrightarrow{[\theta, \cdot]} \text{End}(E) \otimes K_X(D).
\]

**Lemma 5.8.** Infinitesimal deformations of \((E, \delta, \theta)\) along \(\mathcal{M}_H^\Delta(r, d)\) are parametrized by \(\mathbb{H}^1(\mathcal{C}_\Delta^\bullet)\).

In particular, the dimension of \(\mathcal{M}_H^\Delta(r, d)\) is

\[
\dim \mathcal{M}_H^\Delta(r, d) = 2 \dim \mathcal{K}.
\]

**Proof.** The proof that the complex parametrizes the right deformations follows the same arguments as Lemma 2.6.

We see that \(\mathbb{H}^0(\mathcal{C}_\Delta^\bullet) = 0\) just as in Corollary 2.4. If the underlying bundle is stable, we have moreover that \(\mathbb{H}^2(\mathcal{C}_\Delta^\bullet) = 0\) (as the dual complex has no zero hypercohomology).

So the tangent space at a point with underlying stable bundle is identified with \(\mathbb{H}^1(\mathcal{C}_\Delta^\bullet)\).

To compute dimensions, by vanishing of all hypercohomology groups other than the first one, it follows that

\[
\dim \mathbb{H}^1(\mathcal{C}_\Delta^\bullet) = \chi(\text{End}(E) \otimes K_X(D)) - \chi(\ker(\pi)).
\]

By definition

\[
\chi(\ker(\pi)) = \chi(\text{End}(E)) - \chi(\text{Diag}_E) = -r^2(g - 1) - nr.
\]

Also:

\[
\chi(\text{End}(E) \otimes K_X(D)) = r^2(g - 1 + n).
\]

So

\[
\dim \mathbb{H}^1(\mathcal{C}_\Delta^\bullet) = r^2(2g - 2) + nr(r + 1)
\]

and the statement follows. \(\Box\)

**Remark 5.9.** Dimension can also be calculated by using that \(\mathcal{M}_H^\Delta(r, d)\) is a \((\mathbb{C}^\times)^{nr-1}\) torsor over \(\mathcal{N}_H(r, d)\). Indeed

\[
\dim \mathcal{M}_H^\Delta(r, d) = \dim \mathcal{P} = nr - 1 + \dim \text{Jac}_\mathcal{K}(\mathfrak{X}).
\]

Also, by [Bo, (3.1.8)]

\[
\dim \text{Jac}_\mathcal{K} = \dim \mathcal{N}_H(r, d) = r^2(2g - 2 + n) + 1.
\]

Finally,

\[
\dim \mathcal{M}_H^\Delta(r, d) = 2 \left( r^2(g - 1) + r(r + 1) \frac{1}{2} \right) = 2 \dim \mathcal{K}.
\]

**Remark 5.10.** Note that \(\Psi_{|\mathcal{M}_H^\Delta}\) is degenerate. Indeed, non-degeneracy of \(\Psi\) is a consequence of Serre duality

\[
H^1(\text{End}(-D) \cong H^0(\text{End}(E) \otimes K_X(D))^*.
\]

Since \(h^1(\ker(\pi)) < h^1(\text{End}(E)(-D))\) whenever \(E\) is stable, degeneracy of \(\Psi_{|\mathcal{M}_H^\Delta}\) follows for dimensional reasons.
Proposition 5.11. Let $$h^\Delta : \mathcal{M}_H^\Delta(r,d) \to \mathcal{H}$$ be the restriction of the Hitchin map. Then:

1. $$h^\Delta$$ is surjective,
2. the generic fibers are semiabelian varieties. More precisely

$$(h^\Delta)^{-1}(b) = \{(L, \gamma) : L \in \text{Jac}(X), \gamma = (\gamma_1, \ldots, \gamma_r); \gamma_i : L_{y_i} \cong L_{y_i}, y_i \in \pi_b^{-1}(x_i)\}/\mathbb{C}^\times.$$ 

Proof. Surjectivity follows immediately from that of $$\tilde{h}$$. As for semiabelian-ness of the fibers, it follows from Proposition 5.5, together with [BSU, Proposition 7.2.1].

5.3. Comparison of two integrable systems: completing the Hitchin system. In this section we compare the Hitchin systems $$h$$ and $$\tilde{h}$$ defined in (5.1) and (5.4) respectively.

First of all, note that the symplectic structure on $$\mathcal{M}_H(r,d)$$ completes the Poisson structure of $$\mathcal{N}_H(r,d)$$. Now, in what follows we argue that this is done somewhat perpendicularly to the Hitchin fibers of $$\mathcal{N}_H(r,d)$$. In particular, in order to obtain extra action angle coordinates to (locally) recover, for example, the semiabelian subvarieties appearing in Proposition 5.11, new functions need to be added to the system.

By Proposition 4.2, we have that locally $$\mathcal{O}_{\mathcal{M}_H} = \mathcal{O}_X \otimes_{\mathbb{C}} \mathcal{O}_{\text{GL}_r/G_m}$$.

Consider the embedding

$$\text{GL}_r(\mathbb{C})^n/\mathbb{C}^\times \hookrightarrow \text{PGL}_{rn}(\mathbb{C}).$$ (5.9)

Proposition 5.12. Let $$f \in \mathcal{O}_{\text{GL}_r/G_m}$$ be a local function supported on the fibers of $$Q$$. Then

$$\{f, h_i\} = 0$$

for all $$i = 1, \ldots, N$$. In particular, consider the (local) coordinate functions $$x_i$$ on the maximal torus of an affine open subset of $$\text{GL}_r(\mathbb{C})^n/\mathbb{C}^\times$$ (defined for instance via the embedding (5.9)). Then the following set of local functions Poisson commutes

$$\{x_i, h_k\}_{1 \leq i \leq nr-1, k=1,\ldots,N}.$$ 

Moreover, the associated Hamiltonian vectors are linear on the fibers of the local map

$$(h_1, \ldots, h_N, x_1, \ldots, x_{nr-1}) : \mathcal{M}_H(r,d) \to \mathbb{C}^{r^2(g-1)+r(r+1)n+nr-1}.$$ 

Proof. Since the computation is local, we may assume the torsor (4.3) is trivial.

Consider the following commutative diagram:

$$
\begin{array}{cccc}
H^0(\text{End}(E)|_D)/\mathbb{C} & \to & H^1(C_\bullet) & \to & H^1(\text{End}(E)(-D)) \\
\downarrow & & & & \downarrow dQ \\
H^0(\text{End}(E) \otimes K_X(D)) & \to & H^1(C_\bullet^+) & \to & H^1(\text{End}(E))
\end{array}
$$ (5.10)
The second and third lines give a decomposition of the tangent spaces at a point \((E, \delta, \theta) \in \mathcal{M}_H(r, d)\) and \(Q(E, \delta, \theta) = (E, \theta) \in \mathcal{N}_H(r, d)\) respectively, while the first row is the tangent space of \(Q^{-1}(E, \theta)\).

Now, represent \(v \in T_{(E, \delta, \theta)} \mathcal{M}_H\) as \((\mu_{ij}, \eta_i)\). Note that
\[
\mu_{ij} = (\sigma_i - \sigma_j, \rho_{ij}),
\]
where \(\sigma_i \in H^0(\text{End}(E)(-D))\) are local functions with the same restriction to \(D\), namely \(\sigma_i - \sigma_j \in \text{Im}(H^0(\text{End}(E)|_D) \to H^1(\text{End}(E)(-D)))\), and \(\rho_{ij} \in H^1(\text{End}(E))\).

Now, clearly, for \(f \in O_{\text{GL}/G_m}\), we have
\[
\text{df}(\mu_{ij}, \eta_i) = \text{df}(\sigma_i - \sigma_j, \eta_i) = (\text{df}(\sigma_k|_D), 0).
\]
In order to assign to \(df\) an element of \(H^1(\mathcal{E}^\bullet)\), consider the diagram dual to (5.10):

\[
\begin{array}{cccc}
V & \downarrow & H^0(\text{End}(E) \otimes K_X(D)) & \downarrow \text{df} \uparrow \\
& & \text{Im}(\mathcal{E}^\bullet) & \text{Im}(\mathcal{E}^\bullet)^* \downarrow \\
& & H^1(\text{End}(E)(-D)) & H^1(\text{End}(E)(-D))
\end{array}
\]

where \(V \subset H^0(\text{End}(E) \otimes K_X(D)|_D)\) is the image of the restriction map
\[
H^0(\text{End}(E) \otimes K_X(D)) \to H^0(\text{End}(E) \otimes K_X(D)|_D).
\]
Note that Serre duality pairing between \(H^0(\text{End}(E) \otimes K_X(D))\) and \(H^1(\text{End}(E)(-D))\) identifies
\[
H^0(\text{End}(E)|_D) \cong H^0(\text{End}(E) \otimes K_X(D)|_D)^*, \; H^0(\text{End}(E) \otimes K) \to H^1(\text{End}(E))^*.
\]
So \(df\) is represented by an element \((\sigma_i, 0)\) where \(\sigma_i \in V \subset H^0(\text{End}(E) \otimes K_X(D)|_D)\). We have \((\sigma_i, 0) \in \mathcal{H}^1(\mathcal{E}^\bullet)\), as \(\sigma_i - \sigma_j = [0, \theta]\).

Now, \(dh_k\) is represented by \((0, \text{itr}\theta^{k-1})\), where \(\text{itr}\theta^{k-1}\) is interpreted as a 1-cocycle of \(\text{End}(E)(-D)\) as follows: choose a point \(p \in X\) with local coordinate \(z\) on an open neighborhood \(U\) such that \(K_X(D)|_U \cong \mathcal{O}_U\). Let \(U_{12} = U \setminus P = U \cap X \setminus \{P\}\). Then
\[
\theta^{k-1}|_{U_{12}} \in H^0(U_{12}, \text{End}(E)).
\]
Moreover, \(K|_U \cong \mathcal{O}(-D),\) so the meromorphic form \(dz/z\) generates \(H^1(X, K_X)\) and moreover \(\theta^k dz/z \in \Gamma(U_{12}, \text{End}E(-D))\). We may check that this defines a cocycle.

Now, on \(U_{12}\), we have \(K \cong (-D)\), and the pairing of \(\theta^k dz/z\) with any element of \(V\) will be identically zero. It thus follows that
\[
\{f, h_k\} = 0.
\]

Finally, since Serre duality restricts on the fibers of \(\mathcal{M}_H(r, d)\) to the Killing form, the functions on the moduli space, given by the coordinate functions of the maximal torus, Poisson commute.
The last statement follows because of (a) linearity of $X_{h_k}$ on the Jacobian of the spectral curve, (b) vanishing of $X_{h_k}$ on the fibers of $Q$, (c) linearity of $X_{x_i}$ on $(\mathbb{C}^*)^{nr-1}$ and (d) vanishing of $X_{x_i}$ on $\text{Jac}(X_b)$.
