Editor:

Abstract

Due to the high cost of communication, federated learning (FL) systems need to sample a subset of clients that are involved in each round of training. As a result, client sampling plays an important role in FL systems as it affects the convergence rate of optimization algorithms used to train machine learning models. Despite its importance, there is limited work on how to sample clients effectively. In this paper, we cast client sampling as an online learning task with bandit feedback, which we solve with an online stochastic mirror descent (OSMD) algorithm designed to minimize the sampling variance. We then theoretically show how our sampling method can improve the convergence speed of optimization algorithms. To handle the tuning parameters in OSMD that depend on the unknown problem parameters, we use the online ensemble method and doubling trick. We prove a dynamic regret bound relative to any sampling sequence. The regret bound depends on the total variation of the comparator sequence, which naturally captures the intrinsic difficulty of the problem. To the best of our knowledge, these theoretical contributions are new and the proof technique is of independent interest. Through both synthetic and real data experiments, we illustrate advantages of the proposed client sampling algorithm over the widely used uniform sampling and existing online learning based sampling strategies. The proposed adaptive sampling procedure is applicable beyond the FL problem studied here and can be used to improve the performance of stochastic optimization procedures such as stochastic gradient descent and stochastic coordinate descent.
1. Introduction

Modern edge devices, such as personal mobile phones, wearable devices, and sensor systems in vehicles, collect large amounts of data that are valuable for training of machine learning models. If each device only uses its local data to train a model, the resulting generalization performance will be limited due to the number of available samples on each device. Traditional approaches where data are transferred to a central server, which trains a model based on all available data, have fallen out of fashion due to privacy concerns and high communication costs. Federated Learning (FL) has emerged as a paradigm that allows for collaboration between different devices (clients) to train a global model while keeping data locally and only exchanging model updates (McMahan et al., 2017).

In a typical FL process, we have clients that contain data and a central server that orchestrates the training process (Kairouz et al., 2021). The following process is repeated until the model is trained: (i) the server selects a subset of available clients; (ii) the server broadcasts the current model parameters and sometimes also a training program (e.g., a Tensorflow graph (Abadi et al., 2016)); (iii) the selected clients make updates to the model parameters based on their local data; (iv) the local model updates are uploaded to the server; (v) the server aggregates the local updates and makes a global update of the shared model. In this paper, we focus on the first step and develop a practical strategy for selecting clients with provable guarantees.

To train a machine learning model in a FL setting with $M$ clients, we would like to minimize the following objective:

$$\min_w F(w) := \sum_{m \in [M]} \lambda_m \phi(w; D_m),$$

where $\phi(w; D_m)$ is the loss function used to assess the quality of a machine learning model parameterized by the vector $w$ based on the local data $D_m$ on the client $m \in [M]$. The parameter $\lambda_m$ denotes the weight for client $m$. Typically, we have $\lambda_m = n_m/n$, where $n_m = |D_m|$ is the number of samples on the client $m$, and the total number of samples is $n = \sum_{m=1}^{M} n_m$. At the beginning of the $t$-th communication round, the server uses the sampling distribution $p^t = (p^t_1, \ldots, p^t_M)^\top$ to choose $K$ clients by sampling with replacement from $[M]^2$. Let $S^t \subseteq [M]$ denote the set of chosen clients with $|S^t| = K$. The server transmits the current model parameter vector $w^t$ to each client $m \in S^t$. The client $m$

---

1. We use $[M]$ to denote the set $\{1, \ldots, M\}$.
2. In this paper, we assume that all clients are available in each round and the purpose of client sampling is to reduce the communication cost, which is also the case considered by some previous research (Chen et al., 2020). However, in practice, it is possible that only a subset of clients are available at the beginning of each round due to physical constraint. In Section 9.2, we discuss how to extend our proposed methods to deal with such situations. Analyzing such an extension is highly non-trivial and we leave it for further study. See detailed discussion in Section 9.2.
computes the local update $g_t^m$ and sends it back to the server. After receiving local updates from clients in $S^t$, the server constructs a stochastic estimate of the global gradient as
\[
g^t = \frac{1}{K} \sum_{m \in S^t} \frac{\lambda_m}{p_m} g^t_m,
\]
and makes the global update of the parameter $w^{t}$ using $g^t$. For example, $w^{t+1} = w^{t} - \mu^t g^t$, if the server is using stochastic gradient descent (SGD) with the stepsize sequence $\{\mu^t\}_{t \geq 1}$ (Bottou et al., 2018). However, the global update can be obtained using other procedures as well.

The sampling distribution in FL is typically uniform over clients, that is, $p^t = p^{\text{unif}} = (1/M, \ldots, 1/M)^\top$. However, nonuniform sampling (also called importance sampling) can lead to faster convergence, both in theory and practice, as has been illustrated in stochastic optimization (Zhao and Zhang, 2015; Needell et al., 2016). While the sampling distribution can be designed based on prior knowledge (Zhao and Zhang, 2015; Johnson and Guestrin, 2018; Needell et al., 2016; Stich et al., 2017), we cast the problem of choosing the sampling distribution as an online learning task and need no prior knowledge about (1).

Existing approaches to designing a sampling distribution using online learning focus on estimation of the best sampling distribution under the assumption that it does not change during the training process. However, the best sampling distribution changes with iterations during the training process, and the target stationary distribution does not capture the best sampling distribution in each round. In the existing literature, the best fixed distribution in hindsight is used as the comparator to measure the performance of the algorithm used to design the sampling distribution. Here, we focus on measuring the performance of the proposed algorithm against the best dynamic sampling distribution. We use an online stochastic mirror descent (OSMD) algorithm to generate a sequence of sampling distributions and prove a regret bound relative to any dynamic comparators that involve a total variation term that characterizes the intrinsic difficulty of the problem. To the best of our knowledge, this is the first bound on the dynamic regret with intrinsic difficulty characterization in importance sampling. Moreover, we theoretically show how our sampling method improves the convergence guarantee of optimization method by reducing the dependency on the heterogeneity of the problem.

### 1.1 Contributions

We develop an algorithm based on OSMD that generates a sequence of sampling distributions $\{p^t\}_{t \geq 1}$ based on the partial feedback available to the server from the sampled clients. We prove a bound on regret relative to the any dynamic comparators, which allows us to consider the best sequence of sampling distributions as they change over iterations. The bound includes a total variation term that characterizes the intrinsic difficulty of the problem.

---

3. Here by model update, we actually mean the negative direction of model update. For example, when applying gradient descent, we refer the gradient as the model update, while the model parameter makes an update at the direction of the negative gradient. We stick with the term model update since it is more commonly used.

4. Throughout the paper, except in Section 6, we do not specify how $g^t_m$ is obtained. One possibility that the reader could keep in mind for concreteness is the LocalUpdate algorithm (Charles and Konečný, 2020), which covers well-known algorithms such as mini-batch SGD and FedAvg (McMahan et al., 2017).
problem by capturing the difficulty of following the best sequence of distributions. Such a characterization of problem difficulty is novel. Besides, our theoretical result can recover the results in previous research as special cases and is thus strictly more general. Moreover, we theoretically improve the convergence guarantee of optimization algorithm by using our sampling scheme over uniform sampling. We show that adaptive sampling can help reduce the dependency on the heterogeneity level of the problem.

We demonstrate the empirical superiority of the proposed algorithm through synthetic and real data experiments. In addition to client sampling in FL, our proposed algorithm will have a broad impact on stochastic optimization. Adapting our algorithm to any stochastic optimization procedure that chooses samples, such as SGD, or coordinates, such as Stochastic Coordinate Descent, may improve their performance. For example, Zhao et al. (2022) illustrated the practical benefits of our algorithm to speed up L-SVRG and L-Katyusha.

The learning rate of the proposed algorithm depends on the total variation of the comparator sequence, which is generally unknown. Furthermore, it also depends on the total number of iterations that can also be unknown. We make the algorithm practical by adapting the follow-the-regularized-leader algorithm and doubling trick to automatically choose the learning rate that performs as well as the best learning rate asymptotically.

1.2 Notation

Let \( \mathbb{R}_+^M = [0, \infty)^M \) and \( \mathbb{R}^M_{++} = (0, \infty)^M \). For \( M \in \mathbb{N}^+ \), let \( \mathcal{P}_{M-1} := \{ x \in \mathbb{R}^M : \sum_{i=1}^M x_i = 1 \} \) be the \((M-1)\)-dimensional probability simplex. We use \( p = (p_1, \ldots, p_M) \) to denote a sampling distribution with support on \([M] := \{1, \ldots, M\}\). We use \( p^{1:T} \) to denote a sequence of sampling distributions \( \{p_t\}_{t=1}^T \). Let \( \Phi : \mathcal{D} \subseteq \mathbb{R}^M \rightarrow \mathbb{R} \) be a differentiable convex function defined on \( \mathcal{D} \), where \( \mathcal{D} \) is a convex open set, and we use \( \mathcal{D} \) to denote the closure of \( \mathcal{D} \). The Bregman divergence between any \( x, y \in \mathcal{D} \) with respect to the function \( \Phi \) is given as \( D_\Phi(x \mid y) = \Phi(x) - \Phi(y) - \langle \nabla \Phi(y), x - y \rangle \). The unnormalized negative entropy is denoted as \( \Phi_e(x) = \sum_{m=1}^M x_m \log x_m - \sum_{m=1}^M x_m, \; x = (x_1, \ldots, x_M)^\top \in \mathcal{D} = \mathbb{R}^M_+ \), with 0 log 0 defined as 0. We use \( \| \cdot \|_p \) to denote the \( L_p \)-norm for \( 1 \leq p \leq \infty \). For \( x \in \mathbb{R}^n \), we have \( \| x \|_p = (\sum_{i=1}^n x_i^p)^{1/p} \) when \( 1 < p < \infty \), \( \| x \|_1 = \sum_{i=1}^n |x_i| \), and \( \| x \|_\infty = \max_{1 \leq i \leq n} |x_i| \). Given any \( L_p \)-norm \( \| \cdot \|_p \), we define its dual norm as \( \| z \|_* := \sup \{ z^\top x : \| x \|_p \leq 1 \} \). We use \( |\mathcal{B}| \) to denote the cardinality of the index set \( |\mathcal{B}| \).

For two sequences \( \{a_n\} \) and \( \{b_n\} \), we use \( a_n = O(b_n) \) or \( a_n \lesssim b_n \) if there exists \( C > 0 \) such that \( |a_n|/b_n| \leq C \) for all \( n \) large enough; \( a_n = \Theta(b_n) \) if \( a_n = O(b_n) \) and \( b_n = O(a_n) \) simultaneously. Similarly, \( a_n = \tilde{O}(b_n) \) if \( a_n = O(b_n \log^k b_n) \) for some \( k \geq 0 \); \( a_n = \tilde{\Theta}(b_n) \) if \( a_n = \tilde{O}(b_n) \) and \( b_n = \tilde{O}(a_n) \) simultaneously.

1.3 Organization of the Paper

We summarize the related work in Section 2. We motivate importance sampling in FL and introduce an adaptive client sampling algorithm in Section 3. We then establish a bound on the dynamic regret in Section 4. We introduce several extensions of our main algorithms in Section 5. More specifically, in Section 5.1 and Section 5.2, we design two extensions to the sampling algorithm that make it adaptive to the unknown problem parameters; and in Section 5.3, we discuss how to extend our algorithm to sampling without replacement. We derive optimization guarantee of mini-batch SGD and FedAvg using our sampling scheme.
in Section 6. We provide the experimental results on synthetic data in Section 7 and real-world data in Section 8. Finally, we give conclusions and discussions about future directions in Section 9. We leave all the technical proofs in appendix.

Code to replicate the results in this paper is available at https://github.com/boxinz17/FL-Client-Sampling.

2. Related Work

Our paper is related to client sampling in FL, importance sampling in stochastic optimization, and online convex optimization. We summarize only the most relevant literature, without attempting to provide an extensive survey.

For client sampling, Chen et al. (2020) proposed to use the theoretically optimal sampling distribution to choose clients. However, their method requires all clients to compute local updates in each round, which is impractical due to stragglers. Ribero and Vikalo (2020) modelled the parameters of the model during training by an Ornstein-Uhlenbeck process, which was then used to derive an optimal sampling distribution. Cho et al. (2020b) developed a biased client selection strategy and analyzed its convergence property. As a result, the algorithm has a non-vanishing bias and is not guaranteed to converge to optimum. Moreover, it needs to involve more clients than our method and is thus communication and computational more expensive. Kim et al. (2020); Cho et al. (2020a); Yang et al. (2020) considered client sampling as a multi-armed bandit problem, but provided only limited theoretical results. Wang et al. (2020) used reinforcement learning for client sampling with the objective of maximizing accuracy, while minimizing the number of communication rounds.

Our paper is also closely related to importance sampling in stochastic optimization. Zhao and Zhang (2015); Needell et al. (2016) illustrated that by sampling observations from a nonuniform distribution when using a gradient-based stochastic optimization method, one can achieve faster convergence. They designed a fixed sampling distribution using prior knowledge on the upper bounds of gradient norms. Csiba and Richtárik (2018) extended the importance sampling to mini-batches. Stich et al. (2017); Johnson and Guestrin (2018); Gopal (2016) developed adaptive sampling strategies that allow the sampling distribution to change over time. Nesterov (2012); Perekrestenko et al. (2017); Zhu et al. (2016); Salehi et al. (2018) discussed importance sampling in stochastic coordinate descent methods. Namkoong et al. (2017); Salehi et al. (2017); Borsos et al. (2018, 2019); Hanchi and Stephens (2020) illustrated how to design the sampling distribution by solving an online learning task with bandit feedback. Namkoong et al. (2017); Salehi et al. (2017) designed the sampling distribution by solving a multi-armed bandit problem with the EXP3 algorithm (Lattimore and Szepesvári, 2020. Chapter 11). Borsos et al. (2018) used the follow-the-regularized-leader algorithm (Lattimore and Szepesvári, 2020. Chapter 28) to solve an online convex optimization problem and make updates to the sampling distribution. Borsos et al. (2019) restricted the sampling distribution to be a linear combination of distributions in a predefined set and used an online Newton step to make updates to the mixture weights. The above approaches estimate a stationary distribution, while the best distribution is changing with iterations and, therefore, is intrinsically dynamic. In addition to having suboptimal empirical performance, these papers provide theoretical results that only establish a regret.
relative to a fixed sampling distribution in hindsight. To address this problem, Hanchi and Stephens (2020) took a non-stationary approach where the most recent information for each client was kept. A decreasing stepsize sequence is required to establish a regret bound. Furthermore, the regret bound does not capture the intrinsic difficulty of the problem. In comparison, we establish a regret bound relative to a dynamic comparator—a sequence of sampling distributions—without imposing assumptions on the stepsize sequence, and this bound includes the dependence on the total variation term characterizing the intrinsic difficulty of the problem.

Our paper also contributes to the literature on online convex optimization. We cast the client sampling problem as an online learning problem (Hazan, 2016) and adapt algorithms from the dynamic online convex optimization literature to solve it. Hall and Willett (2015); Yang et al. (2016); Daniely et al. (2015) proposed methods that achieve sublinear dynamic regret relative to dynamic comparator sequences. In particular, Hall and Willett (2015) used a dynamic mirror descent algorithm to achieve sublinear dynamic regret with total variation characterizing the intrinsic difficulty of the environment. However, the optimal tuning parameters depend on the unknown total variation. On the other hand, van Erven and Koolen (2016); Zhang et al. (2018) proposed different online ensemble approaches to automatically choose the tuning parameters for online gradient descent. Compared with the problem settings in the above studies, there are two key new challenges that we need to address. First, we only have partial information—bandit feedback—instead of the full information about the loss functions. Second, the loss functions in our case are unbounded, which violates the common boundedness assumption in the online learning literature. To overcome the first difficulty, we construct an unbiased estimator of the loss function and its gradient, which are then used to make an update to the sampling distribution. We address the second challenge by first bounding the regret of our algorithm when the sampling distributions in the comparator sequence lie in a region of the simplex for which the loss is bounded, and subsequently analyze the additional regret introduced by projecting the elements of the comparator sequence to this region.

3. Adaptive Client Sampling

We show how to cast the client sampling problem as an online learning task. Subsequently, we solve the online learning problem using OSMD algorithm.

3.1 Client Sampling as an Online Learning Problem

Recall that at the beginning of the $t$-th communication round, the server uses a sampling distribution $p^t$ to choose a set of clients $S^t$, by sampling with replacement $K$ clients from $[M]$, to update the parameter vector $w^t$. For a chosen client $m \in S^t$, the local update is denoted as $g^t_m$. For example, the local update $g^t_m = \nabla \phi(w^t; D_m)$ may be the full gradient; when mini-batch SGD/FedSGD is used, then $g^t_m = (1/B) \sum_{b=1}^{B} \nabla \phi(w^{t,b}; \xi^{t,b}_m)$, where $\xi^{t,b}_m \sim D_m$ and $B$ is the batch size; when FedAvg is used, then $g^t_m = w^t - w^{t,b}_m$, where $w^{t,b}_m = w^{t,b-1}_m - \mu^t \nabla f (w^{t,b-1}_m; \xi^{t,b-1}_m)$, $b = 0,\ldots,B-1$, $w^{t,0}_m = w^t$, $\xi^{t,b}_m \sim D_m$, and $\mu^t$ is the local stepsize at $t$-th communication round. We define the aggregated oracle update at the $t$-th
communication round as
$$J^t = \sum_{m=1}^{M} \lambda_m g^t_m.$$  

The oracle update $J^t$ is constructed only for theoretical purposes and is not computed in practice. The stochastic estimate $g^t$, defined in (2), is an unbiased estimate of $J^t$, that is, $\mathbb{E}_{S^t}[g^t] = J^t$. Note that we only consider the randomness of $S^t$ and treat $g^t_m$ as given.

The variance of $g^t$ is
$$\mathbb{V}_{S^t}[g^t] = \frac{1}{K} \left( \sum_{m=1}^{M} \frac{\lambda_m^2 \|g^t_m\|^2}{p^t_m} - \|J^t\|^2 \right). \quad (3)$$

Our goal is to design the sampling distribution $p^t$, used to sample $S^t$, so to minimize the variance in (3). In doing so, we can ignore the second term as it is independent of $p^t$.

Let $a^t_m = \frac{\lambda_m^2 \|g^t_m\|^2}{c}$, where $c > 0$ is a positive constant to make sure that $\mathbb{E}[\|g^t_m\|^2]/c = \Theta(1)$. Except in Section 6.2, we simply take $c = 1$ to simplify the discussion in the rest of the paper. For any sampling distribution $q = (q_1, \ldots, q_M)^T$, the variance reduction loss $l_t(q)$ is defined as
$$l_t(q) = \frac{1}{K} \sum_{m=1}^{M} \frac{a^t_m}{q_m}. \quad (4)$$

Then for $S^t$ sampled via $q$, we have
$$\mathbb{V}_{S^t}[g^t] = l_t(q) - \frac{1}{K} \|J^t\|^2.$$  

Given a sequence of sampling distributions $q^{1:T}$, the cumulative variance reduction loss is defined as $L(q^{1:T}) := \sum_{t=1}^{T} l_t(q^t)$. When the choice of $q^{1:T}$ is random, the expected cumulative variance reduction loss is defined as $\mathbb{E}[L(q^{1:T})]$.

The variance reduction loss appears in the bound on the sub-optimality of a stochastic optimization algorithm. As a motivating example, suppose $F(\cdot)$ in (1) is $\nu$-strongly convex. Furthermore, suppose the local update $g^t_m = \nabla \phi(w^t; D_m)$ is the full gradient of the local loss and the global update is made by SGD with stepsize $\mu^t = 2/((\nu t))$. Theorem 3 of Salehi et al. (2017) then states that for any $T \geq 1$:
$$\mathbb{E} \left[ F \left( \frac{2}{T(T+1)} \sum_{t=1}^{T} t \cdot w^t \right) \right] - F(w^*) \leq \frac{2}{\nu T(T+1)} \mathbb{E}[L(p^{1:T})], \quad (5)$$

where $w^*$ is the minimizer of the objective in (1). Therefore, by choosing the sequence of sampling distributions $p^{1:T}$ to make the $\mathbb{E}[L(p^{1:T})]$ small, one can achieve faster convergence. This observation holds in other stochastic optimization problems as well. We develop an algorithm that creates a sequence of sampling distributions $p^{1:T}$ to minimize $\mathbb{E}[L(p^{1:T})]$ using only the norm of local updates, and without imposing assumptions on the loss functions.

---

5. The randomness comes from two sampling processes. The first sampling happens on clients level, and the second sampling happens locally when choosing samples. Client sampling is dealing with the first randomness. To ease the understanding, one may treat $g^t_m$ as full local gradient.

6. The variance reduction loss $l_t(\cdot)$ should be distinguished from the training loss $\phi(\cdot)$. While the former is always convex, $\phi(\cdot)$ can be non-convex.
or how the local and global updates are made. As a result, the algorithm can be applied to
design sampling distributions for essentially any stochastic optimization procedure. In
Section 6, we show how our sampling method improves the upper bound of mini-batch SGD
and FedAvg (McMahan et al., 2017) with non-convex objectives.

Suppose that at the beginning of the $t$-th communication round we know all $\{a^t_m\}_{m=1}^M$. Then the optimal sampling distribution
\begin{equation}
    p^t_\star = (p^t_{\star,1}, \ldots, p^t_{\star,M})^\top = \arg \min_{p \in \mathcal{P}_{M-1}} l_t(p)
\end{equation}
is obtained as $p^t_{\star,m} = \sqrt{a^t_m}/(\sum_{m=1}^M \sqrt{a^t_m})$. Computing the distribution $p^t_\star$ is impractical as it
requires local updates of all clients, which eradicates the need for client sampling. From
the form of $p^t_\star$, we observe that clients with a large $a^t_m$ are more “important” and should
have a higher probability of being selected. Since we do not know $\{a^t_m\}_{m=1}^M$, we will need to
explore the environment to learn about the importance of clients before we can exploit
the best strategy. Finally, we note that the relative importance of clients will change over
time, which makes the environment dynamic and challenging.

Based on the above discussion, we cast the problem of creating a sequence of sampling
distributions as an online learning task with bandit feedback, where a game is played be-
tween the server and environment. Let $p^1$ be the initial sampling distribution. At the
beginning of iteration $t$, the server samples with replacement $K$ clients from $[M]$, denoted
by $S^t$, using $p^t$. The environment reveals $\{a^t_m\}_{m \in S^t}$ to the server, where $a^t_m = \lambda_m \|g^t_m\|^2$.
The environment also computes $l_t(p^t)$; however, this loss is not revealed to the server. The
server then updates $p^{t+1}$ based on the feedback $\{(a^t_m)_{m \in S^t}^{t}\}_{t=1}^T$ and sampling distributions $\{p^u\}_{u=1}^t$. Note that in this game, the server only gets information about the chosen clients and,
based on this partial information, or bandit feedback, needs to update the sampling
distribution. On the other hand, we would like to be competitive with an oracle that can
calculate the cumulative variance reduction loss. We will design $p^t$ in a way that is agnostic
to the generation mechanism of $\{a^t\}_{t \geq 1}$, and will treat the environment as deterministic,
with randomness coming only from $\{S^t\}_{t \geq 1}$ when designing $p^t$. We describe an OSMD-based
approach to solve this online learning problem.

### 3.2 OSMD Sampler

The variance-reduction loss function $l_t$ is a convex function on $\mathcal{P}_{M-1}$ and
\begin{equation}
    \nabla l_t(q) = -\frac{1}{K} \left( \frac{a^t_1}{(q_1)^2}, \ldots, \frac{a^t_M}{(q_M)^2} \right)^\top \in \mathbb{R}^M \quad \text{for all} \quad q = (q_1, \ldots, q_M)^\top \in \mathbb{R}_{++}^M.
\end{equation}
Since we do not observe $a^t$, we cannot compute $l_t(\cdot)$ or $\nabla l_t(\cdot)$. Instead, we can construct
unbiased estimates of them. For any $q \in \mathcal{P}_{M-1}$, let $\hat{l}_t(q; p^t)$ be an estimate of $l_t(q)$ defined as
\begin{equation}
    \hat{l}_t(q; p^t) = \frac{1}{K^2} \sum_{m=1}^M \frac{a^t_m}{q_m p^t_m} N \{m \in S^t\},
\end{equation}
and $\nabla \hat{l}_t(q; p^t) \in \mathbb{R}^M$ has the $m$-th entry defined as
\begin{equation}
    \left[ \nabla \hat{l}_t(q; p^t) \right]_m = -\frac{1}{K^2} \cdot \frac{a^t_m}{q^2_m p^t_m} N \{m \in S^t\}.
\end{equation}
When number of times that a client \( m \) satisfies \( l \), to the best of our knowledge, while similar estimators as \( \hat{p} \) in previous methods. For updating sampling distribution, this is one of the differences between our method and literature (Borsos et al., 2018), we are the first one to propose \( \nabla l \). The set \( S^t \) is sampled with replacement from \( [M] \) using \( p^t \) and \( N \{ m \in S^t \} \) denote the number of times that a client \( m \) is chosen in \( S^t \). Thus, \( 0 \leq N \{ m \in S^t \} \leq K \). Given \( q \) and \( p^t \), \( \hat{l}^t(q;p^t) \) and \( \nabla \hat{l}^t(q;p^t) \) are random variables in \( \mathbb{R} \) and \( \mathbb{R}^M \) that satisfy

\[
\mathbb{E}_{S^t} \left[ \hat{l}^t(q;p^t) \mid p^t \right] = l^t(q), \quad \mathbb{E}_{S^t} \left[ \nabla \hat{l}^t(q;p^t) \mid p^t \right] = \nabla l^t(q).
\]

When \( S^t \) and \( p^t \in \mathbb{R}^M_{++} \) are given, \( \hat{l}^t(q;p^t) \) is a convex function with respect to \( q \) on \( \mathbb{R}^M_{++} \) and satisfies \( \hat{l}^t(q;p^t) - \hat{l}^t(q';p^t) \leq \langle \nabla \hat{l}^t(q;p^t), q - q' \rangle \), for \( q, q' \in \mathbb{R}^M_{++} \). The constructed estimates \( \hat{l}^t(q;p^t) \) and \( \nabla \hat{l}^t(q;p^t) \) are crucial for designing updates to the sampling distribution. To the best of our knowledge, while similar estimators as \( \hat{l}^t(q;p^t) \) in (6) was used in previous literature (Borsos et al., 2018), we are the first one to propose \( \nabla \hat{l}^t(q;p^t) \) in (7) and use it for updating sampling distribution. This is one of the differences between our method and previous methods.

OSMD Sampler is an online stochastic mirror descent algorithm for updating the sampling distribution, detailed in Algorithm 1. The sampling distribution is restricted to lie in the space \( A = \mathcal{P}_{M-1} \cap [\alpha/M, \infty)^M \), \( \alpha \in (0, 1] \), to prevent the server from assigning small probabilities to devices. Let \( \Phi : \mathcal{D} \subseteq \mathbb{R}^M \mapsto \mathbb{R} \) be a continuously differentiable convex function defined on \( \mathcal{D} \), with \( A \subseteq \mathcal{D} \). The learning rates \( \{ \eta_t \}_{t \geq 1} \) are positive and nonincreasing.\(^7\)

Line 7 of Algorithm 1 provides an update to the sampling distribution using the mirror descent update. The available feedback is used to construct an estimate of the loss, while the Bregman divergence between the current and next sampling distribution is used as a regularizer, ensuring that the updated sampling distribution does not change too much. The update only uses the most recent information, while forgetting the history, which results in nonstationarity of the sequence of sampling distributions. In Line 5 of Algorithm 1, we choose \( S^t \) by sampling with replacement. In Section 5.3, we discuss how to extend the results to sampling without replacement.

The mirror descent update in Line 7 is not available in a closed form in general and an iterative solver may be needed. However, when \( \Phi(\cdot) \) is chosen as the negative entropy \( \Phi_e(\cdot) \) (we use this as our default choice), a closed-form efficient solution can be obtained. Based on Proposition 15 in Appendix A.1, an efficient implementation is shown in Algorithm 2.

\(^7\) We use the term learning rate when discussing an online algorithm that learns a sampling distribution, while the term stepsize is used in the context of an optimization algorithm.
Algorithm 2 Solver of Step 7 of Algorithm 1 when $\Phi$ is unnormalized negative entropy

1: **Input:** $\tilde{p}^t$, $S^t$, $\{a_m^t\}_{m \in S^t}$, and $A = \mathcal{P}_{M-1} \cap [\alpha/M, \infty)^M$.
2: **Output:** $\tilde{p}^{t+1}$.
3: Let $\tilde{p}_m^{t+1} = p_m^t \exp \{ N \{ m \in S^t \} \eta_t a_m^t / (K^2(p_m^t)^3) \}$ for $m \in [M]$.
4: Sort $\{\tilde{p}_m^{t+1}\}_{m=1}^M$ in a non-decreasing order: $\tilde{p}_m^{t+1} \leq \tilde{p}_{m+1}^{t+1} \leq \cdots \leq \tilde{p}_{M}^{t+1}$.
5: Let $v_m = \tilde{p}_{\pi(m)}^{t+1} (1 - \frac{m-1}{M})$ for $m \in [M]$.
6: Let $u_m = \frac{\alpha}{M} \sum_{j=m}^M \tilde{p}_{\pi(j)}^{t+1}$ for $m \in [M]$.
7: Find the smallest $m$ such that $v_m > u_m$, denoted as $m^*_i$.
8: Let $\tilde{p}_m^{t+1} = \begin{cases} \frac{\alpha}{M} & \text{if } \pi(m) < m^*_i \\ (1 - ((m^*_i - 1)/M)\alpha)\tilde{p}_m^{t+1} / \left( \sum_{j=m^*_i}^M \tilde{p}_{\pi(j)}^{t+1} \right) & \text{otherwise.} \end{cases}$

The main cost comes from sorting the sequence $\{\tilde{p}_m^{t+1}\}_{m=1}^M$, which can be done with the computational complexity of $O(M \log M)$. However, note that we only update a few entries of $p^t$ to get $\tilde{p}^{t+1}$ and $p^t$ is sorted. Therefore, most entries of $\tilde{p}^{t+1}$ are already sorted. Using this observation, we can usually achieve a much faster running time, for example, by using an adaptive sorting algorithm (Estivill-Castro and Wood, 1992).

Next, we provide a bound on the dynamic regret for OSMD Sampler.

4. Dynamic Regret of OSMD Sampler

We first describe the dynamic regret used to measure the performance of an online algorithm that generates a sequence of sampling distributions $\{\tilde{p}\}_{t \geq 0}$ in a non-stationary environment. Given any comparator sequence $q^{1:T} \in \mathcal{P}_{M-1}^T$, the dynamic regret is defined as

$$ \text{D-Regret}_T(q^{1:T}) = \bar{L}(\tilde{p}^{1:T}) - \bar{L}(q^{1:T}). $$

In contrast, the static regret measures the performance of an algorithm relative to the best fixed sampling distribution, that is, it restricts $q^1 = \cdots = q^T$ (Namkoong et al., 2017; Salehi et al., 2017; Borsos et al., 2018, 2019). When using a fixed comparator $q^1 = \cdots = q^t = q$, we write the regret as $\text{D-Regret}_T(q)$.

The following quantity describes the dynamic complexity of a comparator sequence and will appear in the regret bound below.

**Definition 1 (Total Variation)** The total variation of a comparator sequence $q^{1:T}$ with respect to the norm $\| \cdot \|$ on $\mathbb{R}^M$ is $TV(q^{1:T}) = \sum_{t=1}^{T-1} \| q^{t+1} - q^t \|$.

The total variation measures how variable a sequence is. The larger the total variation $TV(q^{1:T})$, the more variable $q^{1:T}$ is, and such a comparator sequence is harder to match. To give an upper bound on the dynamic regret of OSMD Sampler, we need the following assumptions.

**Assumption 2** The function $\Phi(\cdot)$ is $\rho$-strongly convex, $\rho > 0$ with respect to $\| \cdot \|$: $\Phi(x) \geq \Phi(y) + \langle \nabla \Phi(y), x - y \rangle + \frac{\rho}{2} \| x - y \|^2$, $x, y \in \mathcal{D}$.
Assumption 3 There exist positive functions $H(M, \alpha)$, $\{Q_t(M, \alpha)\}_{t \geq 1}$, and $D_{\text{max}}(M, \alpha)$, such that $\|\nabla \Phi(p)\|_* \leq H(M, \alpha)$, $\|\nabla l_t(p; q)\|_* \leq Q_t(M, \alpha)$ almost surely, and $D_{\Phi}(q \parallel p^{\text{unif}}) \leq D_{\text{max}}(M, \alpha)$ for all $p, q \in A$.

These assumptions are standard in the literature (Hall and Willett, 2015). When we choose $\Phi = \Phi_e$ and $\| \cdot \parallel = \| \cdot \parallel_1$, these assumptions hold (See Appendix A.3). Under Assumption 2, we have $D_{\Phi}(x \parallel y) \geq (\rho^2/2)\|x - y\|^2$. To simplify the notation, we will omit $M$ and $\alpha$ from $H$, $\{Q_t\}_{t \geq 1}$, and $D_{\text{max}}$. We also need the following quantities that quantify how far $q^t$ is from $A$. Given $q^t \in P_{M-1}$ and $\alpha \in (0, 1]$, let

$$
\psi(q^t, \alpha) := \sum_{m=1}^M \left( \frac{\alpha}{M} - q^t_m \right) \mathbb{1} \left\{ q^t_m < \frac{\alpha}{M} \right\}, \quad \omega(q^t, \alpha) := \frac{\sum_{m=1}^M (\frac{\alpha}{M} - q^t_m) \mathbb{1} \left\{ q^t_m < \frac{\alpha}{M} \right\}}{\sum_{m=1}^M (\frac{\alpha}{M} - q^t_m) \mathbb{1} \left\{ q^t_m \geq \frac{\alpha}{M} \right\}},
$$

$$
\phi(q^t, \alpha) := \frac{\omega(q^t, \alpha)}{1 - \omega(q^t, \alpha) (1 - \frac{\alpha}{M})}.
$$

We will use these quantities to characterize the projection error in the following theorem, which is the main result of this section.

Theorem 4 Suppose Assumptions 2-3 hold and we use $\| \cdot \parallel = \| \cdot \parallel_1$ to define the total variation. Assume that $\{\eta_t\}_{t \geq 1}$ is a nonincreasing sequence. Let $p^{1:T}$ be a sequence generated by Algorithm 1. For any comparator sequence $q^{1:T}$, where $q^t$ is allowed to be deterministic or random, we have

$$
\text{D-Regret}_T(q^{1:T}) \leq \frac{D_{\text{max}}}{\eta_1} + \frac{2H}{\eta_T} \mathbb{E} \left[ TV(q^{1:T}) \right] + \frac{2}{\rho} \sum_{t=1}^T \eta_t \mathbb{E} \left[ Q_t^2 \right] + \left[ \psi(q^t, \alpha) \right] + \sum_{t=1}^T \left[ \phi(q^t, \alpha) l_t(q^t) \right].
$$

Proof The major challenge of the proof is to construct a projection of any comparator sequence $q^{1:T}$ onto $A^T$ and bound the projection error. To the best of our knowledge, this bound on the projection error of a dynamic sequence is novel. Since the comparator sequence can be arbitrary, thus analyzing the projection error is nontrivial. Another challenge is to deal with the dynamic comparator, which requires us to connect the cumulative regret with the total variation of the comparator sequence. See Appendix A.2 for more details.  

From Theorem 1, we see that the bound on the dynamic regret consists of two parts. The first part is the intrinsic regret, quantifying the difficulty of tracking a comparator sequence in $A^T$; the second part is the projection error, arising from projecting the comparator sequence onto $A^T$. Note that the intrinsic regret depends on $\alpha$ through $D_{\text{max}}$, $H$, and $\{Q_t\}_{t \geq 1}$. As shown in Appendix A.2, we have $0 \leq \omega(q^t, \alpha) \leq 1$ for all $\alpha \in [0, 1]$, which implies that $\phi(q^t, \alpha) \leq M/\alpha$. Furthermore, $\psi(q^t, \alpha) \leq \sum_{m=1}^M (\alpha/M) \mathbb{1} \left\{ q^t_m < (\alpha/M) \right\} \leq \alpha$. 

Therefore, the projection error can be upper bounded by \((8H/\eta_T + (M/\alpha) \sum_{t=1}^{T} l_t(q^t))\). More importantly, when \(q^t_{\alpha} \in A\), we have \(\psi(q^t, \alpha) = \omega(q^t, \alpha) = \phi(q^t, \alpha) = 0\). Thus, when the comparator sequence belongs to \(A^T\), the projection error vanishes and we only have the intrinsic regret. As \(\alpha\) decreases from one to zero, the intrinsic regret gets larger (it often tends to infinity as shown in Corollary 17), while we are allowing a larger class of comparator sequences; on the other hand, the projection error decreases to zero, since the gap between \(A\) and \(P_{M-1}\) vanishes with \(\alpha\). An optimal choice of \(\alpha\) balances the two sources of regret.

When \(\| \cdot \| = \| \cdot \|_1\) and \(\Phi\) is the unnormalized negative entropy, the Step 7 of Algorithm 1 has a closed-form solution (see Proposition 15). By Pinsker’s inequality, the unnormalized negative entropy \(\Phi_e(x)\) is 1-strongly convex on \(P_{M-1}\) with respect to \(\| \cdot \|_1\). When \(q^{1:T}\) is a deterministic sequence, we have \(E[TV(q^{1:T})] = TV(q^{1:T})\).

With Theorem 4, we have the following corollary.

**Corollary 5** Suppose conditions of Theorem 1 hold and let \(\hat{p}^{1:T}\) be the sequence generated by Algorithm 1. For any comparator sequence \(q^{1:T}\), we choose \(\alpha\) such that \(q^t \in A\) for all \(t \in [T]\). Let

\[
\eta = \frac{K^2 \alpha^3}{M^3} \sqrt{\log M + 2 \log (M/\alpha) \mathbb{E}[TV(q^{1:T})]} \cdot \frac{2}{2 \sum_{t=1}^{T} \mathbb{E}[(\bar{a}^t)^2]}.
\]

Then

\[
D\text{-Regret}_T(q^{1:T}) \leq \frac{2\sqrt{2M^3}}{K^2 \alpha^3} \sqrt{\log M + 2 \log (M/\alpha) \mathbb{E}[TV(q^{1:T})]} \sum_{t=1}^{T} \mathbb{E}[(\bar{a}^t)^2],
\]

where \(\bar{a}^t := \max_{1 \leq m \leq M} x_m^2 \| g_m^t \|^2 = \max_{1 \leq m \leq M} a_m^t\) for all \(t \in [T]\).

**Proof** The proof follows directly from Corollary 17 in Appendix A.3.

Note that as the training proceeds, the norms of local updates are decreasing, thus \({\bar{a}^t}_{t=1}^{T}\) is typically a decreasing sequence. Thus, a naive upper bound is \(\sum_{t=1}^{T} \mathbb{E}[(\bar{a}^t)^2] = O(T)\). However, in Section 7.6, we empirically show that \(\bar{a}^t\) decreases fast and the cumulative square sum of this sequence will converge to a constant, that is, \(\sum_{t=1}^{T} \mathbb{E}[(\bar{a}^t)^2] = O(1)\). This result further implies that the static regret with respect to the best fixed sampling distribution in hindsight (where \(TV(q^{1:T}) = 0\)) is empirically \(O(1)\), which is much better than the rates in previous research (Salehi et al., 2017; Borsos et al., 2018). Besides, our regret analysis also allows for sampling distributions that change over time (where \(TV(q^{1:T}) > 0\)), and thus is more general than previous results.

### 5. Extensions of OSMD Sampler

In this section, we discuss several extensions of OSMD Sampler. In Section 5.1 and Section 5.2, we discuss how to automatically choose the learning rates. In Section 5.3, we discuss how to extend OSMD sampler to sample without replacement setting.
5.1 Adaptive-OSMD Sampler

There are two main tuning parameters in OSMD Sampler, namely $\alpha$ and the learning rates \( \{\eta_t\}_{t \geq 1} \). As we will show empirically in Section 7.3, the performance of the algorithm is relatively robust to the choice of $\alpha$. However, the choice of the sequence of learning rates \( \{\eta_t\}_{t \geq 1} \) may have a large effect on the performance of OSMD Sampler. One may want to choose the learning rate by (10), but it depends on several unknown quantities, thus may not be practical. The aim of this and the next section is to choose the learning rate without the need to know any unknown quantities.

First, to get rid of the dependency on $\sum_{t=1}^{T} \mathbb{E} [(\bar{a}^t)^2]$, similar to Corollary 5, we can have the following Corollary.

**Corollary 6** Suppose conditions of Theorem 1 hold and let $\hat{p}^{1:T}$ be the sequence generated by Algorithm 1. We choose $\alpha$ such that $p^* \in \mathcal{A}$ for all $t \in [T]$. Let

\[
\eta = \frac{K^2 \alpha^3}{M^3 \sqrt{\mathbb{E} [(\bar{a}^1)^2]}} \sqrt{\frac{\log M + 2 \log (M/\alpha) \mathbb{E} [TV(p^1:T)]}{2T}}.
\]

Then

\[
D\text{-Regret}_T(p^1:T) \leq \frac{2 \sqrt{2} M^3 \sqrt{\mathbb{E} [(\bar{a}^1)^2]}}{K^2 \alpha^3} \sqrt{\log M + 2 \log (M/\alpha) \mathbb{E} [TV(p^1:T)]} T,
\]

where $\bar{a}^t := \max_{1 \leq m \leq M} a^t_m = \max_{1 \leq m \leq M} \lambda^2_m \|g^0_m\|^2$.

The choice in (11) still depends on unknown quantities such as $\mathbb{E} [\bar{a}^1]$, $\mathbb{E} [TV(p^1:T)]$, and $T$. To get $\mathbb{E} [\bar{a}^1]$, we can add a pre-training phase where we broadcast the initial model parameter $w^0$ to all devices before the start of the training, and collect the returned $\|g^0_m\|^2$ from all responsive devices, which we denote as $S^0$. Then $\bar{a}^1 := \max_{m \in S^0} \lambda_m \|g^0_m\|^2$. On the other hand, $\mathbb{E} [TV(p^1:T)]$ and $T$ are hard to estimate in advance of the training. We discuss how to use an online ensemble method to choose the learning rate without the knowledge of $\mathbb{E} [TV(p^1:T)]$, and how to get rid of the dependence on $T$ using the doubling trick.

The main idea is to run a set of expert algorithms, each with a different learning rate for Algorithm 1. We then use a prediction-with-expert-advice algorithm to track the best performing expert algorithm. More specifically, we define the set of expert learning rates as

\[
\mathcal{E} := \left\{ 2^{e-1} \cdot \frac{K^2 \alpha^3}{M^3 \sqrt{\mathbb{E} [(\bar{a}^1)^2]}} \sqrt{\frac{\log M + 2 \log (M/\alpha) \mathbb{E} [TV(p^1:T)]}{2T}} \middle| e = 1, 2, \ldots, E \right\},
\]

where

\[
E = \left\lfloor \frac{1}{2} \log_2 \left( 1 + \frac{4 \log (M/\alpha)}{\log M} (T - 1) \right) \right\rfloor + 1.
\]

Then for each $\eta_e \in \mathcal{E}$, Adaptive-OSMD Sampler algorithm runs an expert algorithm to generate a sequence of sampling distributions $\hat{p}^1_e:T$. Meanwhile, it also runs a meta-algorithm that uses exponentially-weighted-average strategy to aggregate $\{\hat{p}^1_e:T\}_{e=1}^E$ into a single output $\hat{p}^1:T$, which achieves performance close to the best expert.

---

8. We refer the reader to Chapter 2 of Cesa-Bianchi and Lugosi (2006) for an overview of prediction-with-expert-advice algorithms.
Algorithm 3: Adaptive-OSMD Sampler

1: Input: Meta learning rate \( \gamma \); the set of expert learning rates \( \mathcal{E} = \{ \eta_1 \leq \eta_2 \leq \cdots \leq \eta_E \} \) with \( E = |\mathcal{E}| \); parameter \( \alpha \in (0, 1] \), \( A = \mathcal{P}_{M-1} \cap [\alpha/M, \infty)^M \); number of iterations \( T \); initial distribution \( p^{\text{init}} \).

2: Output: \( \hat{p}^{1:T} \).

3: Set \( \theta^1_e = (1 + 1/E)/(e(e + 1)) \) and \( \hat{p}^1_e = p^{\text{init}}, e \in [E] \).

4: for \( t = 1, 2, \ldots, T - 1 \) do

5: Compute \( \hat{p}^t = \sum_{e=1}^{E} \theta^t_e \hat{p}^t_e \).

6: Sample \( S^t \) by \( \hat{p}^t \).

7: for \( e = 1, 2, \ldots, E \) do

8: Compute \( \hat{l}_t(\hat{p}^t_e; \hat{p}^t) \) via (6) and \( \nabla \hat{l}_t(\hat{p}^t_e; \hat{p}^t) \) via (7).

9: Solve \( \hat{p}^{t+1}_e = \arg \min_{p \in A} \eta_e(p, \nabla \hat{l}_t(\hat{p}^t_e; \hat{p}^t)) + D_\Phi(p \parallel \hat{p}^t_e) \) via Algorithm 2.

10: end for

11: Update the weight of each expert:

\[
\theta^{t+1}_e = \frac{\theta^t_e \exp \left\{ - \gamma \hat{l}_t(\hat{p}^t_e; \hat{p}^t) \right\}}{\sum_{e=1}^{E} \theta^t_e \exp \left\{ - \gamma \hat{l}_t(\hat{p}^t_e; \hat{p}^t) \right\}}, \quad e \in [E].
\]

12: end for

Algorithm 3 details Adaptive-OSMD Sampler. Note that since we can compute \( \hat{l}_t(\hat{p}^t_e; \hat{p}^t) \) and \( \nabla \hat{l}_t(\hat{p}^t_e; \hat{p}^t) \) directly, there is no need to use a surrogate loss as in van Erven and Koolen (2016) and Zhang et al. (2018).

From the computational perspective, the major cost comes from solving step 9 of Algorithm 3, which needs to be run for a total number of \( T|\mathcal{E}| = T\lceil \log_2 T \rceil \) times. Compared with Algorithm 1, the computational complexity only increases by a \( \log(T) \) factor. We have the following result on Algorithm 3.

Theorem 7 Let \( \Phi = \Phi_e \) and we use \( \| \cdot \| = \| \cdot \|_1 \) to define total variation. Let \( \alpha \) be small enough such that \( p^*_t \in A \) for all \( t \in [T] \). Let \( p^{1:T} \) be the output of Algorithm 3 with \( \gamma = \alpha M \sqrt{\frac{8K}{T \mathbb{E}[\bar{a}^1]}} \), \( p^{\text{init}} = p^{\text{init}} \) and \( \mathcal{E} \) as in (13). Then

\[
D\text{-Regret}_T \leq \frac{3\sqrt{2}M^3 \sqrt{\mathbb{E}[(\bar{a}^1)^2]}}{K^2 \alpha^3} \sqrt{T \log M + 2 \log (M/\alpha) \mathbb{E} [TV(p^*_1:T)]} + \frac{M}{\alpha} \sqrt{\frac{T \mathbb{E} [\bar{a}^1]}{8K}} (1 + 2 \log E).
\]

Proof See Appendix A.4.

Since the additional regret term is \( \tilde{O}((M/\alpha)\sqrt{T/K}) \), which is no larger than the first term asymptotically, the bound on the regret is of the same order as in (12). However, we do not need to know the total variation \( \mathbb{E}[TV(p^*_1:T)] \) to set the learning rate.
5.2 Adaptive-OSMD Sampler with Doubling Trick

Algorithm 3 requires the total number of iterations $T$ as input, which is not always available in practice. In those cases, we use doubling trick (Cesa-Bianchi and Lugosi, 2006, Section 2.3) to avoid this requirement. The basic idea is to restart Adaptive-OSMD Sampler at exponentially increasing time points $T_b = 2^{b-1}$, $b \geq 1$. The learning rates of experts in Algorithm 3 are reset at the beginning of each time interval, and the meta-algorithm learning rate $\gamma$ is chosen optimally for the interval length. We set $\bar{a}_{T_b}$ at the beginning of each time interval using the maximum environment feedback from the previous interval.

More specifically, at the time point $T_b$, we let

$$E_b := \left\lfloor \frac{1}{2} \log_2 \left( 1 + \frac{4 \log(M/\alpha)}{\log M} (2^{b-1} - 1) \right) \right\rfloor + 1,$$

and $\gamma_b = \frac{\alpha}{M} \sqrt{\frac{8K}{2^{b-1} - \hat{a}_b^2}}$, $b \geq 1$. We set $\hat{a}_{T_b} = \max_{m \in S_{T_b-1}} a_m^{T_b-1}$. In a practical implementation, at the time point $t = T_b$, instead of initializing all expert algorithms using uniform distribution, we can initialize them with the output of the meta-algorithm for $t = T_b - 1$. To get $a_0$, the server uses a pre-training phase where the initial model parameter $w_0$ is broadcast to all devices before the start of the training. Subsequently, the server collects the returned $\|g_m^0\|^2$ from all responsive devices, which are denoted as $S^0$. Then $\hat{a}_1 := \max_{m \in S^0} a_0^m$ where $a_0^m = \lambda_m \|g_m^0\|^2$. Adaptive-Doubling-OSMD Sampler is detailed in Algorithm 4.

From the computational perspective, by the proof of Theorem 8, Algorithm 4 needs to run Step 9 of Algorithm 3 for a total number of $O(T \mid E \mid^2) = O(T \log_2 T)$ times. Therefore, the computational complexity of Adaptive-Doubling-OSMD Sampler is asymptotically the same as that of Adaptive-OSMD Sampler, while it increases by only a $\log(T)$ factor compared to OSMD Sampler. The following theorem provides a bound on the dynamic regret for Adaptive-Doubling-OSMD Sampler.

**Theorem 8** Let $\Phi = \Phi_e$ and we use $\| \cdot \| = \| \cdot \|_1$ to define the total variation. Let $\alpha$ be small enough constant so that $p_1^{1:T} \in \mathcal{A}^T$ and the training is stopped after $T$ iterations. Suppose that there exists a constant $C > 1$ such that $\hat{a}_b^{T_b} \leq C \bar{a}_b^{T_b}$ for all $b = 1, 2, \ldots, B$, where $B = \lfloor \log_2(T + 1) \rfloor$. Let $\hat{p}^{1:T}$ be the output of Algorithm 4, where $p_{\text{unif}}$ is used in Step 8. Then

$$D-\text{Regret}_T \leq \frac{\sqrt{2(T + 1)}}{\sqrt{2} - 1} \left\{ \frac{(2C + 1)\sqrt{M^3 \sqrt{\mathbb{E}[(\hat{a})^2]}}}{{K^2 \alpha^3}} \sqrt{\log M + 2 \log (M/\alpha) \mathbb{E} [TV(p_1^{1:T})]} + \frac{M}{\alpha} \sqrt{\frac{\mathbb{E}[(\hat{a})^2]}{8K}} (C + 2 \log E) \right\}.$$

**Proof** See Appendix A.5. □
Algorithm 4 Adaptive-OSMD Sampler with Doubling Trick (Adaptive-Doubling-OSMD)

1: **Input:** Parameter $\alpha$.
2: **Output:** $\hat{p}_t$ for $t = 1, \ldots, T$.
3: Use $w^0$ to get $\{a_m^0\}_{m \in S^0}$, where $S^0$ is the set of responsive clients in the pre-training phase.
4: Initialize $\hat{a}_1 = \max_{m \in S^0} a_m^0$ and set $b = 1$.
5: while True do
6:   Set $E_k^b$ as in (15).
7:   Let $\gamma_k^b = \alpha \sqrt{\frac{8K}{2^{k-1}q^2}}$.
8:   Obtain $\{\hat{p}_t^b\}_{t=2^{b-1}}^{2^b-1}$ from Algorithm 3 with parameters: $\gamma_k^b, E_k^b, \alpha$, the number of iterations $2^{b-1}$, and the initial distribution $p^\text{unif}$ or $p^{2^{b-1}-1}$ (when $b > 1$).
9:   if Training Process is Converged then
10:      Break.
11:   end if
12:   Let $b \leftarrow b + 1$.
13:   Let $\hat{a}^b = \max_{m \in [M]} a_m^b$.
14: end while

From Theorem 8 we observe that the asymptotic regret bound has the same order as that of OSMD Sampler and Adaptive-OSMD Sampler. However, Adaptive-Doubling-OSMD Sampler does not need to know $\mathbb{E}[\text{TV}(p^{1:T})]$ or $T$ in advance.

5.3 Adaptive Sampling Without Replacement

In the discussion so far, we have assumed that the set $S^t$ is obtained by sampling with replacement from $p^t$. However, when $K$ is relatively large compared to $M$ and $p^t$ is far from uniform distribution, sampling without replacement can be more efficient than sampling with replacement. However, when sampling without replacement using $p^t$, the variance reduction loss does not have a clean form as in (4). As a result, an online design of the sampling distribution is more challenging. In this section, we discuss how to use the sampling distribution obtained by Adaptive-OSMD Sampler to sample clients without replacement, following the approach taken in Hanchi and Stephens (2020).

The detailed sampling procedure is described in Algorithm 5. We still use Adaptive-OSMD Sampler to update the sampling distribution. However, we use the designed sampling distribution in a way that no client is chosen twice. Furthermore, Step 18 of Algorithm 5 constructs the gradient estimate with the following properties.

Proposition 9 (Proposition 3 of Hanchi and Stephens (2020)) Let $\tilde{p}^t = p$ and let $\tilde{g}^t$ be as in Step 18 of Algorithm 5. Note that $\tilde{g}^t = \tilde{g}^t(p)$ depends on $p$. Recall that $J^t = \sum_{m=1}^{M} \lambda_m g_m^t$. We have

$$\mathbb{E}_{S^t}[\tilde{g}^t] = J^t \quad \text{and} \quad \arg \min_{p \in \mathcal{P}_{M-1}} \mathbb{E}_{S^t}[\|\tilde{g}^t - J^t\|^2] = \arg \min_{p \in \mathcal{P}_{M-1}} l_t(p),$$

where $l_t(\cdot)$ is defined in (4) and the expectation is taken over $S^t$. 

16
Algorithm 5 Adaptive sampling without replacement

1: **Input**: $w^1$ and $\hat{p}^1$.
2: for $t = 1, 2, \ldots, T - 1$ do
3:   Let $\hat{p}^t(1) = \hat{p}^t$ and sample $m^t_1$ from $[M]$ by $\hat{p}^t(1)$.
4:   for $k = 2, \ldots, K$ do
5:     /* Design the sampling distribution for sampling the $k$-th client in the $t$-th round */
6:     Construct $\hat{p}^t(k)$ by letting
7:     \[
    \hat{p}^t_{(k),m} = \begin{cases} \left(1 - \sum_{l=1}^{k-1} \hat{p}^t_{m_l}\right)^{-1} \hat{p}^t_{m} & \text{if } m \in [M]\{m^t_1, \ldots, m^t_{k-1}\} \\ 0 & \text{otherwise.} \end{cases}
    \]
8:     /* Sample the $k$-th client */
9:     Sample $m^t_k$ from $[M]\{m^t_1, \ldots, m^t_{k-1}\}$ by $\hat{p}^t(k)$.
10: end for
11: Let $S^t = \{m^t_1, \ldots, m^t_K\}$.
12: The server broadcasts the model parameter $w^t$ to clients in $S^t$.
13: The clients in $S^t$ compute and upload the set of local gradients $\{g^{t}_{m^t_1}, \ldots, g^{t}_{m^t_K}\}$.
14: /* Construct global gradient estimate */
15: Let $g^{t}_{(1)} = \lambda^t_{m^t_1} g^{t}_{m^t_1}/\hat{p}^t_{(1),m^t_1}$.
16: for $k = 2, \ldots, K$ do
17:     Let $g^{t}_{(k)} = \lambda^t_{m^t_k} g^{t}_{m^t_k}/\hat{p}^t_{(k),m^t_k} + \sum_{l=1}^{k-1} \lambda^t_{m^t_l} g^{t}_{m^t_l}$.
18: end for
19: Let $\tilde{g}^t = K^{-1} \sum_{k=1}^{K} g^{t}_{(k)}$.
20: /* Update the model weight based on the global gradient estimate */
21: Obtain the updated model parameter $w^{t+1}$ using $w^t$ and $\tilde{g}^t$.
22: /* Update sampling distribution */
23: Let $a^t_m = \lambda^2_m\|g^t_m\|^2$ for $m \in S^t$.
24: Input $\{a^t_m\}_{m \in S^t}$ into Adaptive-OSMD Sampler to get $\hat{p}^{t+1}$.
25: end for

From Proposition 9, we see that $\tilde{g}^t$ is an unbiased stochastic gradient. Furthermore, the variance of $\tilde{g}^t$ is minimized by the same sampling distribution that minimizes the variance reduction loss in (4). Therefore, it is reasonable to use the sampling distribution generated by Adaptive-OSMD Sampler to design $\tilde{g}^t$.

6. Application of OSMD Sampler on Federated Optimization Algorithms

We illustrate how OSMD Sampler can be used to provably improve the convergence rates of optimization algorithms in federated learning. We choose two most commonly used algorithms in federated learning as our illustrative examples, namely the mini-batch SGD and FedAvg (McMahan et al., 2017). We use these two algorithms as motivating examples to show how adaptive sampling improves the convergence guarantees of optimization algo-

17
rithms. We believe that the analysis in this section can be extended to other optimization algorithms as well.

To simplify the notation, we denote $F_m(w) := \phi(w; D_m)$ and let $\lambda_m = 1/M$ for all $m \in [M]$ in problem (1). Besides, we assume that client objectives are differentiable and $L$-smooth functions.

**Assumption 10** For all $m \in [M]$, $F_m(\cdot)$ is differentiable and $L$-smooth, that is,

$$\|\nabla F_m(x) - \nabla F_m(y)\| \leq L\|x - y\|, \text{ for all } x, y \in \mathbb{R}^d.$$ 

Note that we allow $F_m(\cdot)$ to be non-convex. We also assume that the objective function $F(\cdot)$ is lower-bounded,

**Assumption 11** We assume that $\inf_{w \in F(w)} > -\infty$. We then denote $F^* := \inf_w F(w)$.

In addition, we make the following assumption about the local stochastic gradient.

**Assumption 12** For all $w$ and $m \in [M]$, we have $\mathbb{E}_{\xi \sim D_m} [\nabla \phi(w; \xi)] = \nabla F_m(w)$ and

$$\mathbb{E}_{\xi \sim D_m} \left[\|\nabla \phi(w; \xi) - \nabla F_m(w)\|^2\right] \leq \sigma^2.$$ 

Next, we introduce quantities that characterize the heterogeneity of the optimization problem. Specifically, heterogeneity characterizes how the objective functions of different clients differ from each other. In a federated learning problem, heterogeneity can be large and it is important to understand its effect on the convergence of algorithms. The following three quantities characterize the heterogeneity under different sampling schemes:

$$\zeta_0^2 := \sup_w \frac{1}{M} \sum_{m=1}^{M} \|\nabla F_m(w) - \nabla F(w)\|^2,$$

$$\zeta_1^2 := \min_{p \in \mathcal{P}_{M-1}} \sup_w \left\{ \frac{1}{M^2} \sum_{m=1}^{M} \frac{1}{p_m^2} \|\nabla F_m(w)\|^2 - \|\nabla F(w)\|^2 \right\},$$

$$\zeta_2^2 := \sup_w \left\{ \left( \frac{1}{M} \sum_{m=1}^{M} \|\nabla F_m(w)\| \right)^2 - \|\nabla F(w)\|^2 \right\}.$$ 

(17)

The quantity $\zeta_0$ has been commonly used to quantify the first-order heterogeneity (Karimireddy et al., 2020a,b), while $\zeta_1$ and $\zeta_2$ are variants of $\zeta_0$ corresponding to different sampling schemes. To have a better understanding, let $\tilde{m}$ be a random index drawn from $[M]$, with $\mathbb{P}\{\tilde{m} = m\} = p_m$ for all $m \in [M]$. Then a natural unbiased estimator of $\nabla F(w)$ is $\nabla F_{\tilde{m}}(w)/(M\tilde{p}_m)$. We define

$$\zeta_2^2(w) := \mathbb{E}_{\tilde{m}} \left[ \left\| \frac{1}{M\tilde{p}_m} \nabla F_{\tilde{m}}(w) - \nabla F(w) \right\|^2 \right],$$

where $\mathbb{E}_{\tilde{m}}[\cdot]$ denotes the expectation taken with respect to the random index $\tilde{m}$. $\zeta_2^2(w)$ represents the variance of the unbiased estimator due to client sampling at $w$ and it clearly depends on the sampling distribution for choosing $\tilde{m}$. When we use uniform sampling to
Algorithm 6 Mini-batch SGD with OSMD Sampler

1: Input: Number of communication rounds $T$, number of clients chosen in each round $K$, local batch size $B$, initial model parameter $w^0$, stepsizes $\{\mu_t\}_{t=0}^{T-1}$.
2: Output: The final model parameter $w^T$.
3: Initialize: $\hat{p}^0 = p^{\text{uni-f}}$.
4: for $t = 0, 1, \ldots, T-1$ do
5: Sample $S^t$ with replacement from $[M]$ with probability $\hat{p}^t$, such that $|S^t| = K$.
6: for $m \in S^t$ do
7: Download the current model parameter $w^t$.
8: Locally sample a mini-batch $B^t_m = \{\xi^t_{mb} \}_{b=1}^B$ i.i.d. uniformly random from $[n_m]$, where $|B^t_m| = B$.
9: Locally compute and upload $g^t_m = (1/B) \sum_{b=1}^B \nabla \phi(w^t; \xi^t_{mb})$ to the server.
10: end for
11: Server computes $a^t_m = \lambda^2_m \|g^t_m\|^2$ for $m \in S^t$ and
12: \begin{equation}
    g^t = \frac{1}{K} \sum_{m \in S^t} \frac{\lambda^2_m}{P_m} g^t_m.
\end{equation}
13: Server makes update of the model parameter $w^{t+1} \leftarrow w^t - \mu^t g^t$.
14: Server obtains updated sampling distribution $\hat{p}^{t+1}$ by Algorithm 1.
end for

choose $\tilde{m}$, we then have $\zeta^2_0 = \sup_w \zeta^2(w)$. Besides, the best fixed sampling distribution to minimize $\sup_w \zeta^2(w)$ is
\begin{equation}
    q^* = \arg\min_{q \in \mathcal{P}_{M-1}} \sup_{w} \sum_{m=1}^M \frac{1}{p_m} \|\nabla F_m(w)\|^2,
\end{equation}
and when we choose $\tilde{m}$ by $q^*$, we have $\zeta^2_1 = \sup_w \zeta^2(w)$. Note that $q^*$ is chosen irrespective of $w$. If we allow the sampling distribution to depend on $w$, then the optimal sampling distribution to minimize $\zeta^2(w)$ is $p^*(w)$ with $p^*_m(w) := \|\nabla F_m(w)\|/(\sum_{m'=1}^M \|\nabla F_{m'}(w)\|)$ for all $m = 1, \ldots, M$. When we use $p^*_m(w)$ to choose $\tilde{m}$, we then have $\zeta^2_2 = \sup_w \zeta^2(w)$.

6.1 Convergence Analysis of Mini-batch SGD with OSMD Sampler

In this subsection, we introduce the convergence analysis of mini-batch SGD with OSMD Sampler. The detailed algorithm is given in Algorithm 6. Compared to the classical mini-batch SGD, the key ingredients of Algorithm 6 are Line 13, where the server updates the sampling distribution by OSMD Sampler, and Line 5, where the server samples clients from a non-uniform sampling distribution. Besides, in (19), we use a weighted average to compute the global gradient.

The following quantities are useful in stating the convergence guarantee. Recall that $B$ is the local batch size in Algorithm 6 and $K = |S^t|$. Let $D^F := F(w^0) - F^*$, recall that an upper bound of D-Regret($q^{1:T}$) for any sampling distribution sequence $q^{1:T}$ is given by
Corollary 5, and define

\[
R_{0}^{MB} := \frac{D^F L}{T} + \frac{\sigma \sqrt{DFL}}{\sqrt{T KB}} + \frac{\zeta_0 \sqrt{DFL}}{\sqrt{T K}},
\]

\[
R_{1}^{MB} := \frac{D^F L}{T} + \frac{\sigma \sqrt{DFL}}{\sqrt{T KB \alpha}} + \frac{\zeta_1 \sqrt{DFL}}{\sqrt{T K}} + \frac{\sqrt{DFL} \sqrt{D-\text{Regret}_{T}(q^*)}}{T},
\]

\[
R_{2}^{MB} := \frac{D^F L}{T} + \frac{\sigma \sqrt{DFL}}{\sqrt{T KB \alpha}} + \frac{\zeta_2 \sqrt{DFL}}{\sqrt{T K}} + \frac{\sqrt{DFL} \sqrt{D-\text{Regret}_{T}(p^T_{1:T})}}{T}.
\]

We then have the following convergence guarantee for Algorithm 6.

**Theorem 13**: Assume Assumption 10 and Assumption 12 hold. Let \(\{w^0, \ldots, w^{T-1}\}\) be the sequence of iterates generated by Algorithm 6 and let \(w^R\) denote an element of that sequence chosen uniformly at random.

1. When \(q^* \in A\), let \(\mu_t = \mu\) for all \(t \in [T]\), where

\[
\mu = \min \left\{ \frac{1}{L}, \frac{1}{\sigma} \sqrt{\frac{DF KB \alpha}{LT}}, \frac{1}{\zeta_1} \sqrt{\frac{DF K}{LT}}, \sqrt{\frac{DF}{LD-\text{Regret}_{T}(q^*)}} \right\},
\]

we have \(\mathbb{E} \left[ \|\nabla F(w^R)\|^2 \right] \lesssim R_{1}^{MB}\).

2. When \(p^T_{\star} \in A\) for all \(t \in [T]\), let \(\mu_t = \mu\) for all \(t \in [T]\), where

\[
\mu = \min \left\{ \frac{1}{L}, \frac{1}{\sigma} \sqrt{\frac{DF KB \alpha}{LT}}, \frac{1}{\zeta_1} \sqrt{\frac{DF K}{LT}}, \sqrt{\frac{DF}{LD-\text{Regret}_{T}(p^T_{1:T})}} \right\},
\]

we have \(\mathbb{E} \left[ \|\nabla F(w^R)\|^2 \right] \lesssim R_{2}^{MB}\).

3. When \(q^* \in A\) and \(p^T_{\star} \in A\) both hold, by letting \(\mu_t = \mu\) for all \(t \in [T]\) and appropriately choosing \(\mu\), we have

\[
\mathbb{E} \left[ \|\nabla F(w^R)\|^2 \right] \lesssim \min \{R_{1}^{MB}, R_{2}^{MB}\}.
\]

**Proof**: See detailed proof in Appendix A.6. The key proof technique is to construct a novel ghost subset \(\hat{S}^t\) in each round such that \(\hat{S}^t\) is sampled by the comparator sampling distribution. This way, one can then relate the regret with the difference between the convergence rate under OSMD Sampler and the convergence rate under the comparator sampling distribution. Note that \(\hat{S}^t\) is only constructed for theoretical analysis, and does not need to be actually computed in practice.

We derive different convergence rates \(R_{1}^{MB}\) and \(R_{2}^{MB}\) in Theorem 13 by choosing different comparators, which rates can be applied shall depend on the tuning parameter \(\alpha\) (or equivalently the space \(A\)). More specifically, \(R_{1}^{MB}\) is derived by comparing against \(q^*\) and
$R^\text{MB}_2$ is derived by comparing against $p^1_T$. The different notions of heterogeneity reveals the fact that different sampling schemes can change the convergence speed of optimization algorithms through the change of heterogeneity level.

It is worth noting that one can always choose other comparator sequences besides these two and derive new upper bounds. When choosing a more flexible comparator, one can obtain a smaller heterogeneity, but risk requiring higher regret and larger space $\mathcal{A}$ (which will require smaller $\alpha$). A good choice of comparator should keep a trade-off between these two concerns. We leave how to choose the optimal comparator sequence as a future research direction.

Note that $R^\text{MB}_0$ is the rate of mini-batch SGD under uniform sampling (Ghadimi and Lan, 2013). To see when OSMD Sampler can obtain tighter rates than uniform sampling, we only need $R^\text{MB}_1$ or $R^\text{MB}_2$ to be smaller than $R^\text{MB}_0$.

To have $R^\text{MB}_1 \lesssim R^\text{MB}_0$, we need

$$
(\sigma/\sqrt{K\bar{B}})(1/\sqrt{\alpha} - 1) + \sqrt{\text{D-Regret}_T(q^*)/T} \lesssim (1/\sqrt{K})(\zeta_0 - \zeta_1).
$$

By Corollary 5, we have a worst-case upper bound of $\text{D-Regret}_T(q^*)$ as $O(\sqrt{T})$; empirical evidence in Section 7.6 suggests that we may have $\sum_{t=1}^T E[(\bar{a}^t)^2] = O(1)$, which implies a tighter rate of $\text{D-Regret}_T(q^*)$ as $O(1)$. With either rates, we always have $\text{D-Regret}_T(q^*)/T = o(1)$. Thus, to have $R^\text{MB}_1 \lesssim R^\text{MB}_0$, we only need $(\sigma/\sqrt{B})(1/\sqrt{\alpha} - 1) \ll \zeta_0 - \zeta_1$ asymptotically.

That is, we want the gap between the heterogeneity under best fixed sampling distribution and uniform sampling to be large, compared to $(\sigma/\sqrt{B})(1/\sqrt{\alpha} - 1)$. When $\sigma = 0$, that is, if we use full local gradient, then this is always true. Similarly, to have $R^\text{MB}_2 \lesssim R^\text{MB}_0$, we need

$$
(\sigma/\sqrt{K\bar{B}})(1/\sqrt{\alpha} - 1) + \sqrt{\text{D-Regret}_T(p^*_{t,T})/T} \lesssim (1/\sqrt{K})(\zeta_0 - \zeta_2).
$$

Given that $\sum_{t=1}^T E[(\bar{a}^t)^2] = O(1)$ as justified by the empirical evidence in Section 7.6, we have $\text{D-Regret}_T(p^*_{t,T})$ as $O(\sqrt{T})$. This way, we only need $(\sigma/\sqrt{B})(1/\sqrt{\alpha} - 1) \ll \zeta_0 - \zeta_2$. That is, we want the gap between the heterogeneity under best dynamic sampling distribution and uniform sampling to be large, compared to $(\sigma/\sqrt{B})(1/\sqrt{\alpha} - 1)$. Note that this is always true if $\sigma = 0$.

**New characterization of heterogeneity.** Let $\Delta\zeta_i = \zeta_0 - \zeta_i$ for $i = 1, 2$. Based on the previous analysis, we see that $\Delta\zeta_i$, $i = 1, 2$, can also help measure the dissimilarity of the different clients. Compared with $\zeta_0$, the new characterization reflects how much gain we can have by using non-uniform sampling, where $\Delta\zeta_1$ measures the advantage gained by the fixed sampling distribution, and $\Delta\zeta_2$ measures the advantage gained by the dynamic sampling distribution.

### 6.2 Convergence Analysis of FedAvg with OSMD Sampler

In this subsection, we introduce the convergence guarantee for FedAvg with OSMD Sampler. The detailed algorithm is given in Algorithm 7. Compared to FedAvg in McMahan et al. (2017), the differences between Algorithm 7 are Line 15, where the server updates the sampling distribution by OSMD Sampler, and Line 5, where the server samples clients from a non-uniform sampling distribution. In addition, in (20), we use a weighted average to update the global model parameter. Besides, note that when defining $a^m_m$, we rescale $\|g^m_m\|^2$ by $(\mu^1_t)^2B$, this is to ensure that $E[\|g^m_m\|^2/(\mu^1_t)^2B] = \Theta(1)$ as $\mu^1_t \to 0$ and $B \to \infty$. 
Algorithm 7 FedAvg with OSMD Sampler

1: **Input:** Number of communication rounds $T$, number of clients chosen in each round $K$, number of local steps $B$, initial model parameter $w^0$, global stepsizes $\{\mu^t\}_{t=0}^{T-1}$ and local stepsizes $\{\mu^t_{l}\}_{l=0}^{T-1}$.

2: **Output:** The final model parameter $w^T$.

3: **Initialize:** $p^0 = p^\text{init}$.

4: for $t = 0, 1, \ldots, T - 1$ do

5: Sample $S_t$ with replacement from $[M]$ with probability $p^t$, such that $|S_t| = K$.

6: for $m \in S_t$ do

7: Download the current model parameter $w^t$ and let $w^{t,0}_m = w^t$.

8: for $b = 0, 1, \ldots, B - 1$ do

9: Sample $\xi^t_{m,b}$ from $[n_m]$ uniformly random.

10: Compute $w^{t,b+1}_m = w^{t,b}_m - \mu^t_l \nabla \phi(w^{t,b}_m, \xi^{t,b}_m)$.

11: end for

12: Locally compute $g^t_m = w^t - w^{t,B}_m$ and upload it to the server.

13: end for

14: Server computes

$$a^t_m = \frac{\lambda_m^2 \|g^t_m\|^2}{(\mu^t_l)^2 B} = \frac{\lambda_m^2}{B} \left\| \sum_{b=0}^{B-1} \nabla \phi(w^{t,b}_m, \xi^{t,b}_m) \right\|^2$$

for $m \in S_t$ and let

$$w^{t+1} = w^t - \frac{\mu^t}{K} \sum_{m \in S_t} \frac{\lambda_m}{p^t_m} g^t_m. \quad (20)$$

15: Server obtains updated sampling distribution $p^{t+1}$ by Algorithm 1.

16: end for

The following quantities are useful in stating the convergence guarantee. Recall that $B$ is the local batch size in Algorithm 6 and $K = |S_t|$. Let $D^F := F(w^0) - F^*$,

$$R^0_{\text{Avg}} := \frac{D^F L}{T} + \frac{(D^F L)^2 \xi^2_0}{B^2 T^2} + \frac{(D^F L)^2 \sigma^2}{B T^2} + \frac{\sqrt{D^F L} \xi_0}{\sqrt{T K}} + \frac{\sqrt{D^F L} \sigma}{\sqrt{T K B}},$$

$$R^1_{\text{Avg}} := \frac{D^F L \sqrt{1 + \frac{1}{2\alpha}}}{T} + \frac{(2 + \frac{1}{\alpha}) \frac{1}{2} (D^F L)^\frac{3}{2} \xi^2_0}{T^2} + \frac{(2 + \frac{1}{\alpha}) \frac{1}{2} (D^F L)^\frac{3}{2} \sigma^2}{B T^2} + \frac{\sqrt{D^F L} \xi_1}{\sqrt{T K}} + \frac{\sqrt{D^F L} \sigma}{\sqrt{T K B \alpha}} + \frac{\sqrt{D^F L}}{B \sqrt{T}} \sqrt{\text{D-Regret}_T (q^*)},$$

$$R^2_{\text{Avg}} := \frac{D^F L \sqrt{1 + \frac{1}{2\alpha}}}{T} + \frac{(2 + \frac{1}{\alpha}) \frac{1}{2} (D^F L)^\frac{3}{2} \xi^2_0}{T^2} + \frac{(2 + \frac{1}{\alpha}) \frac{1}{2} (D^F L)^\frac{3}{2} \sigma^2}{B^2 T^2} + \frac{\sqrt{D^F L} \xi_2}{\sqrt{T K}} + \frac{\sqrt{D^F L} \sigma}{\sqrt{T K B \alpha}} + \frac{\sqrt{D^F L}}{B \sqrt{T}} \sqrt{\text{D-Regret}_T (p^{T+1})}. $$
Similar to the result about Mini-batch SGD, we have the following result about FedAvg with OSMD Sampler (Algorithm 7).

**Theorem 14** Assume Assumption 10 and Assumption 12 hold. Let \( \{w^0, \ldots, w^{T-1}\} \) be the sequence of iterates generated by Algorithm 7 and let \( w^R \) denote an element of that sequence chosen uniformly at random.

1. When \( q^* \in \mathcal{A} \), let \( \mu_t = \mu \) and \( \mu_t^l = \mu_l \) for all \( t \). Let \( \mu \geq 1 \) and

\[
\mu_l = \min \left\{ \frac{1}{4\mu BL} \sqrt{\frac{1}{1 + 1/(2\alpha)}}, \frac{(DF)^{\frac{1}{4}}}{(2 + \frac{1}{\alpha})^{\frac{1}{2}} \mu BL^3 \left( \zeta_0^2 + \frac{\sigma^2}{2B} \right)^{\frac{1}{3}} T^{\frac{1}{4}}} \right\},
\]

we have \( \mathbb{E} \left[ \| \nabla F(w^R) \|^2 \right] \lesssim R_{1}^{\text{Avg}} \).

2. When \( p_t^1: T \in \mathcal{A} \) for all \( t \in [T] \), let \( \mu_t = \mu \) and \( \mu_t^l = \mu_l \) for all \( t \). Let \( \mu \geq 1 \) and

\[
\mu_l = \min \left\{ \frac{1}{4\mu BL} \sqrt{\frac{1}{1 + 1/(2\alpha)}}, \frac{(DF)^{\frac{1}{4}}}{(2 + \frac{1}{\alpha})^{\frac{1}{2}} \mu BL^3 \left( \zeta_0^2 + \frac{\sigma^2}{2B} \right)^{\frac{1}{3}} T^{\frac{1}{4}}} \right\},
\]

we have \( \mathbb{E} \left[ \| \nabla F(w^R) \|^2 \right] \lesssim R_{2}^{\text{Avg}} \).

3. When \( q^* \in \mathcal{A} \) and \( p_t^1 \in \mathcal{A} \) both hold, by letting \( \mu_t = \mu \) and \( \mu_t^l = \mu_l \) for all \( t \). Let \( \mu \geq 1 \) and appropriately choose \( \mu_l \), we then have

\[
\mathbb{E} \left[ \| \nabla F(w^R) \|^2 \right] \lesssim \min \{ R_{1}^{\text{Avg}}, R_{2}^{\text{Avg}} \}.
\]

**Proof** See proof in Appendix A.7. Similar to the proof of Theorem 13, the key technique is to construct a novel ghost subset sampled from the comparator sampling distribution.

Note that \( R_{0}^{\text{Avg}} \) is the convergence rate of FedAvg under uniform sampling (Karimireddy et al., 2020b). There are two terms depending on the heterogeneity level: a faster term converges with the rate of \( O(T^{-\frac{3}{4}}) \) and a slower term converges with the rate of \( O(T^{-\frac{1}{2}}) \). When comparing with \( R_{1}^{\text{Avg}} \) and \( R_{2}^{\text{Avg}} \), we see that OSMD Sampler can improve the heterogeneity on the slower term, that is, the asymptotically dominating term.
Besides, similar to the discussion in the previous section, when treating $\alpha$ as constant, we then have $R_{1}^{\text{Avg}} \lesssim R_{0}^{\text{Avg}}$ when

$$(1/B)\sqrt{\text{D-Regret}_T(q^*)/T} \lesssim (1/\sqrt{K})(\zeta_0 - \zeta_1).$$

Since the worst case regret of $\text{D-Regret}_T(q^*)$ is $O(\sqrt{T})$, the above inequality holds as $T \to \infty$. Similarly, $R_{2}^{\text{Avg}} \lesssim R_{0}^{\text{Avg}}$ when

$$(1/B)\sqrt{\text{D-Regret}_T(p_1^{1:T})/T} \lesssim (1/\sqrt{K})(\zeta_0 - \zeta_1).$$

While the the worst case regret of $\text{D-Regret}_T(q^*)$ is $O(T)$; however, as shown in Section 7.6, empirical evidence suggests that we may have $\sum_{t=1}^{T} \mathbb{E}[(\bar{a}_t)^2] = O(1)$, which implies a tighter rate of $\text{D-Regret}_T(p_1^{1:T})$ as $O(\sqrt{T})$. If this is true, then the above inequality also holds asymptotically.

### 7. Synthetic Experiments

In this section, we use synthetic data to demonstrate the performance of Adaptive-OSMD Sampler (Algorithm 3). We compare our method against uniform sampling in Section 7.1 and compare against other bandit feedback online learning samplers in Section 7.2. In addition, we examine the robustness of Adaptive-OSMD Sampler to the choice of $\alpha$ in Section 7.3, while in Section 7.4, we compare it with the sampling without replacement variant discussed in Section 5.3. Finally, in Section 7.6, we show some empirical observation for regret analysis.

We generate data as follows. We set the number of clients as $M = 100$, and each client has $n_m = 100$ samples, $m \in [M]$. Samples on each client are generated as $y_{m,i} = \langle w^*, x_{m,i} \rangle + \mathcal{N}(0, 0.1^2)$, $i \in [n_m]$, (21)

where the coefficient vector $w^* \in \mathbb{R}^d$ has elements generated as i.i.d. $\mathcal{N}(10, 3)$, and the feature vector $x_{m,i} \in \mathbb{R}^d$ is generated as $x_{m,i} \sim \mathcal{N}(0, \Sigma_m)$, where $\Sigma_m = s_m \cdot \Sigma$, $\Sigma$ is a diagonal matrix with $\Sigma_{jj} = \kappa (j-1)/(d-1)$ and $\kappa > 0$ is the condition number of $\Sigma$. We generate $\{s_m\}_{m=1}^{M}$ i.i.d. from $e^{N(0, \sigma^2)}$ and rescale them as $s_m \leftarrow (s_m/\max_{m \in [M]} s_m) \times 10$ so that $s_m \leq 10$ for all $m \in [M]$. In this setting, $\kappa$ controls the difficulty of each problem when solved separately, while $\sigma$ controls the level of heterogeneity across clients. In all experiments, we fix $\kappa = 25$, which corresponds to a hard problem, and change $\sigma$ to simulate different heterogeneity levels. We expect that uniform sampling suffers when the heterogeneity level is high. The dimension $d$ of the problem is set as $d = 10$. The results are averaged over 10 independent runs.

We use the mean squared error loss defined as

$$L(w) = \frac{1}{M} \sum_{m=1}^{M} L_m(w), \quad \text{where} \quad L_m(w) = \frac{1}{2n_m} (y_{m,i} - \langle w^*, x_{m,i} \rangle)^2.$$  

We use the stochastic gradient descent to make global updates. At each round $t$, we choose a subset of $K = 5$ clients, denoted as $S^t$. For each client $m \in S^t$, we choose a mini-batch
Adaptive Client Sampling in Federated Learning

Figure 1: The training loss (top row) and the cumulative regret (bottom row) of Adaptive-OSMD Sampler vs Uniform vs Optimal with $\sigma = 1.0$, $\sigma = 3.0$, and $\sigma = 10.0$. The solid line denotes the mean and the shaded region covers mean ± standard deviation across independent runs.

of samples, $B_m$, of size $\bar{B} = 10$, and compute the mini-batch stochastic gradient. The parameter $w$ is updated as

$$w^{t+1} = w^t + \frac{\mu_{\text{SGD}}}{MK\bar{B}} \sum_{m \in S^t} \frac{1}{p_m} \sum_{i \in B_m^t} (y_{m,i} - \langle w^t, x_{m,i} \rangle) \cdot x_{m,i},$$

where $\mu_{\text{SGD}}$ is the learning rate, set as $\mu_{\text{SGD}} = 0.1$ in simulations.

In all experiments, we set $\alpha$ in Adaptive-OSMD Sampler as $\alpha = 0.4$. The tuning parameters for MABS, VRB and Avare are set as in their original papers.

7.1 Adaptive-OSMD Sampler vs Uniform Sampling

The results of the training process and the cumulative regret are shown in Figure 1. For the training loss, we see that when the heterogeneity level is low ($\sigma = 1.0$), the uniform sampling performs as well as Adaptive-OSMD Sampler and theoretically optimal sampling; however, as the heterogeneity level increases, the performance of uniform sampling gradually suffers; when $\sigma = 10.0$, uniform sampling performs poorly. On the other hand, Adaptive-OSMD Sampler performs well across all levels of heterogeneity and is very close to the theoretically optimal sampling. Similarly, for the cumulative regret, when the heterogeneity level is low, the cumulative regret of uniform sampling is close to Adaptive-OSMD Sampler; however, when the heterogeneity level increases, the cumulative regret of uniform sampling gets much larger than Adaptive-OSMD Sampler. Based on the above results, we can conclude that while the widely used choice of uniform sampling may be reasonable when heterogeneity is low, our proposed sampling strategy is robust across different levels of heterogeneity, and thus should be considered as the default option.
7.2 Adaptive-OSMD Sampler vs MABS vs VRB vs Avare

We compare Adaptive-OSMD Sampler to other bandit feedback online learning samplers: MABS (Salehi et al., 2017), VRB (Borsos et al., 2018) and Avare (Hanchi and Stephens, 2020). Training loss and cumulative regret are shown in Figure 2. We see that while VRB and Avare perform better when the heterogeneity level is low and MABS performs better when the heterogeneity level is high, Adaptive-OSMD Sampler always achieves the best in both training loss and cumulative regret across all different levels of heterogeneity. Thus, we conclude that Adaptive-OSMD is a better choice than other online learning samplers.

7.3 Robustness of Adaptive-OSMD Sampler to the Choice of $\alpha$

We examine the robustness of Adaptive-OSMD Sampler to the choice of $\alpha$. We run Adaptive-OSMD Sampler separately for each $\alpha \in \{0.01, 0.1, 0.4, 0.7, 0.9, 1.0\}$. Note that when $\alpha = 1.0$, the Adaptive-OSMD Sampler outputs a uniform distribution. Training loss and cumulative regret are shown in Figure 3. We observe that Adaptive-OSMD Sampler is robust to the choice of $\alpha$, and performs well as long as $\alpha$ is not too close to zero or too close to one.

7.4 Experiments on Sampling with Replacement vs Without Replacement

We compare sampling with replacement and sampling without replacement when used together with Adaptive-OSMD sampler. Sampling without replacement is described in Section 5.3. Training loss and cumulative regret are shown in Figure 4. We observe that using sampling with replacement results in a slightly smaller cumulative regret and a slightly better training loss. However, these differences are not significant.
Figure 3: The training loss (top row) and the cumulative regret (bottom row) of Adaptive-OSMD Sampler with different choices of $\alpha$ under $\sigma = 1.0$, $\sigma = 3.0$ and $\sigma = 10.0$. The solid line denotes the mean and the shaded region covers mean ± standard deviation across independent runs.

Figure 4: The training loss (top row) and the cumulative regret (bottom row) of Adaptive-OSMD Sampler with replacement vs without replacement across $\sigma = 1.0$, $\sigma = 3.0$ and $\sigma = 10.0$. The solid line denotes the mean and the shaded region covers mean ± standard deviation across independent runs.
Figure 5: The training loss (top row) and the cumulative regret (bottom row) of Adaptive-OSMD Sampler vs $p^{IS}$ across $\nu = 1.0$, $\nu = 3.0$ and $\nu = 10.0$. The solid line denotes the mean and the shaded region covers mean $\pm$ standard deviation across independent runs.

Figure 6: Plots of how $\bar{a}^t$ and $\sum_{t=1}^t (\bar{a}^t)^2$ grow with $t$.

7.5 Dynamic Sampling Distribution v.s. Fixed Sampling Distribution

In this paper, we allow both our sampling distribution and competitor sampling distribution to change over time, while previous studies either use fixed sampling distribution (Zhao and Zhang, 2015; Needell et al., 2016) or they compare against fixed sampling distribution (Namkoong et al., 2017; Salehi et al., 2017; Borsos et al., 2018, 2019). In this section, we show that under certain settings, dynamic sampling distribution can achieve signifi-
Adaptive Client Sampling in Federated Learning

cant advantage over fixed sampling distribution. More specifically, we compare Adaptive-OSMD Sampler with the Lipschitz constant based importance sampling distribution proposed by Zhao and Zhang (2015); Needell et al. (2016), which we denote as $p_{IS}$.

We still use the same model as in (21) to generate data, but we generate $w_*$ and $x_{m,i}$ differently. Motivated by Zhao et al. (2022), for each $m \in [M]$, we choose uniformly at random one dimension among $\mathbb{R}^d$, denoted as $\text{supp}(m) \in [d]$, as the support of $x_{m,i}$ for all $i \in [n_m]$, while the remaining dimensions of $x_{m,i}$ are set to be zero. The nonzero dimension of $x_{m,i}$ is generated from $N(1,0.1^2)$. The entries of $w_*$ are generated i.i.d. from $e^{N(0,\nu^2)}$. Therefore, $\nu$ controls the variance of entries of $w_*$. Besides, we choose the optimal stepsize from the set $\{1.0, 0.5, 0.1, 0.05, 0.01\}$ for each method separately. The final result is shown in Figure 5. We see that Adaptive-OSMD Sampler performs better than $p_{IS}$ across all levels of $\nu$. Note that in practice, in order to implement $p_{IS}$, we need prior information about Lipschitz constants of $L_m(\cdot)$’s, while Adaptive-OSMD Sampler does not need prior information. This way, our proposed method does not only have better practical performance, but also requires less prior information.

7.6 Empirical Observation of Regret

In Corollary 5, we see that the upper bound for the regret of OSMD sampler with respect to any comparator sequence $q^{1:T}$ depends on $\sum_{t=1}^{T}(\bar{a}_t)^2$. In this section, we empirically show how $\bar{a}_t$ and $\sum_{t=1}^{T}(\bar{a}_t)^2$ grow with $t$ in practice. The experimental setting of this section is the same as Section 7.1 and we use AdaOSMD Sampler. In Figure 6, we plot both $\bar{a}_t$ and $\sum_{t=1}^{T}(\bar{a}_t)^2$ over $t$. We see that $\bar{a}_t$ drops to zero fastly. As a result $\sum_{t=1}^{T}(\bar{a}_t)^2$ converges to a constant as $t \to \infty$. This way, we empirically have $\sum_{t=1}^{T}(\bar{a}_t)^2 = O(1)$.

8. Real Data Experiment

We compare Adaptive-OSMD Sampler with uniform sampling and other online learning samplers including MABS (Salehi et al., 2017), VRB (Borsos et al., 2018) and Avare (Hanchi and Stephens, 2020) on real data. We use three commonly used computer vision data sets: MNIST (LeCun and Cortes, 2010), KMNIST (Clanuwat et al., 2018), and FMNIST (Xiao et al., 2017). We set the number of devices to be $M = 500$. To better simulate the situation where our method brings significant convergence speed improvement, we create a highly skewed sample size distribution of the training set among clients: 65% of clients have only one training sample, 20% of clients have 5 training samples, 10% of clients have 30 training samples, and 5% of clients have 100 training samples. This setting tries to illustrate a real-life situation where most of the data come from a small fraction of users, while most of the users have only a small number of samples. The skewed sample size distribution is common in other FL data sets, such as LEAF (Caldas et al., 2018). The sample size dis-

---

10. KMNIST dataset is licensed under a permissive CC BY-SA 4.0 license, except where specified within some benchmark scripts.

11. FMNIST dataset is under The MIT License (MIT) Copyright © [2017] Zalando SE, https://tech.zalando.com
The sample size distribution in the training set across clients is shown in Figure 7. In addition, each client has 10 validation samples used to measure the prediction accuracy of the model over the training process.

We use a multi-class logistic regression model. For a given gray scale picture with the label \( y \in \{1, 2, \ldots, C\} \), we unroll its pixel matrix into a vector \( x \in \mathbb{R}^p \). Given a parameter matrix \( W \in \mathbb{R}^{C \times p} \), the training loss function defined in (1) is

\[
\phi(W; x, y) := l_{\text{CE}}(\varsigma(Wx) ; y),
\]

where \( \varsigma(\cdot) : \mathbb{R}^C \to \mathbb{R}^C \) is the softmax function defined as

\[
[\varsigma(x)]_i = \frac{\exp(x_i)}{\sum_{j=1}^{K} \exp(x_j)}, \quad \text{for all } x \in \mathbb{R}^C,
\]

and \( l_{\text{CE}}(x ; y) = \sum_{i=1}^{C} 1(y = i) \log x_i, \ x \in \mathbb{R}^C, \ y \in \{1, \ldots, C\} \), is the cross-entropy function.

We use the same algorithms and tuning parameters as in Section 7. Learning rate in SGD is set to 0.075 for MNIST and KMNIST, and is set to 0.03 for FMNIST. The total number of communication rounds is to 1,000. In each round of communication, we choose \( K = 10 \) clients to participate (2% of total number of clients). For a chosen client \( m \), we compute its local mini-batch gradient with the batch size equal to \( \min\{5, n_m\} \), where \( n_m \) is the training sample size on the client \( m \).

Figure 8 shows both the training loss and validation accuracy. Each figure shows the average performance over 5 independent runs. We use the same random seed for both Adaptive-OSMD Sampler and competitors, and change random seeds across different runs. The main focus is on minimizing the training loss, and the validation accuracy is only included for completeness. We observe that Adaptive-OSMD Sampler performs better than uniform sampling and other online learning samplers across all data sets.

9. Discussion

We studied the client sampling problem in FL. We proposed an online learning with bandit feedback approach to tackle client sampling. We used online stochastic mirror descent to solve the online learning problem and applied the online ensemble method with doubling.
Figure 8: Comparison between Adaptive-OSMD Sampler, uniform sampler and other online learning samplers on real data in terms of training loss (top row) and validation accuracy (bottom row). Different columns correspond to different data sets. Adaptive-OSMD Sampler is both faster and more stable. The result is the average performance over 5 independent runs.

trick to choose the tuning parameters. We established an upper bound on the dynamic regret relative to the theoretically optimal sequence of sampling distributions. The total variation of the comparator is explicitly included in the upper bound as a measure of the difficulty of the problem. Extensive numerical experiments demonstrated the benefits of our approach over both widely used uniform sampling and other competitors.

In this paper, we have focused on sampling with replacement. However, sampling without replacement would ideally be a more efficient approach. In Section 5.3, we discussed a natural extension of Adaptive-OSMD Sampler to a setting where sampling without replacement is used. However, this approach does not directly minimize the variance of the gradient $g_t$. When sampling without replacement is used, the variance function becomes
more complicated and the design of an algorithm to directly minimize the variance is an interesting future direction.

Besides, in federated learning, privacy is a major concern. In this paper, the non-uniform sampling distribution may make the protection of clients’ privacy more challenging than uniform sampling. One possible solution is to add noise to the gradient feedback and protect the clients’ privacy under the Differential Privacy (DP) concept (Dwork, 2008). However, the added noise may hurt the performance of our sampling design and increase the regret. Studying the trade-off between privacy protection and regret is an important direction for addressing societal concerns in real-world application.

Other fruitful future directions include the design of sampling algorithms for minimizing personalized FL objectives and sampling with physical constraint in FL system, which we discuss next.

9.1 Client Sampling with Personalized FL Objective

Data distributions across clients are often heterogeneous. Personalized FL has emerged as one effective way to handle such heterogeneity (Kulkarni et al., 2020). Hanzely et al. (2021) illustrated how many existing approaches to personalization can be studied through a unified framework, and, in this section, we discuss a natural extension of Adaptive-OSMD Sampler to this personalized objective. Specifically, we study the following optimization problem

\[
\min_{w,\beta} F(w, \beta) := \sum_{m=1}^{M} \lambda_m \phi(w, \beta_m; D_m),
\]  

(22)

where \( w \in \mathbb{R}^{d_0} \) corresponds to the shared parameter and \( \beta = (\beta_1, \ldots, \beta_M) \) with \( \beta_m \in \mathbb{R}^{d_m} \) corresponds to the local parameters. The objective in (22) covers a wide range of personalized federated learning problems (Hanzely et al., 2021). We further generalize the approach and study the following bilevel optimization problem:

\[
\min_w h(w) := \sum_{m=1}^{M} \lambda_m F_m(w, \hat{\beta}_m(w)) := \sum_{m=1}^{M} \lambda_m \phi(w, \hat{\beta}_m(w); D_m)
\]

subject to \( \hat{\beta}_m(w) = \arg \min_{\beta_m} G_m(w, \beta_m) := \phi(w, \beta_m; \bar{D}_m). \)

(23)

When \( D_m = \bar{D}_m \), then (23) recovers (22). When \( D_m \neq \bar{D}_m \), we then optimize the shared and local parameters on different datasets, which may prevent overfitting. The formulation in (23) is closely related to the implicit MAML (Rajeswaran et al., 2019).

In the following, we use \( \nabla_w \) to denote a partial derivative with respect to \( w \) with \( \beta_m \) fixed, \( \nabla_{\beta_m} \) to denote a partial derivative with respect to \( \beta_m \) with \( w \) fixed, and \( \nabla \) to denote a derivative with respect to \( w \) where \( \beta_m(w) \) is treated as a function of \( w \). Let \( \nabla_{\beta_m \beta_m} G_m(w, \beta_m) \in \mathbb{R}^{d_m \times d_m} \) be the Hessian matrix of \( G_m \) with respect to \( \beta_m \) where \( w \) is fixed, and \( \nabla_{w \beta_m}^2 G_m(w, \beta_m) \in \mathbb{R}^{d_0 \times d_m} \) be the Hessian matrix of \( G_m \) with respect to \( w \) and
local updates of the second part. To get an estimate of \( \nabla S \) and \( \nabla S \) for computing both parts, we decouple

\[
\begin{align*}
\left[ \nabla^2_{\beta_m \beta_m} G_m(w, \beta_m) \right]_{i,j} &= \frac{\partial G_m(w, \beta_m)}{\partial \beta_{m,i} \beta_{m,j}} \quad \text{for all } i, j = 1, 2, \ldots, d_m, \\
\left[ \nabla^2_w G_m(w, \beta_m) \right]_{i,j} &= \frac{\partial G_m(w, \beta_m)}{\partial w_i \beta_{m,j}} \quad \text{for all } i = 1, 2, \ldots, d, j = 1, 2, \ldots, d_m.
\end{align*}
\]

By the implicit function theorem, we have

\[
\nabla h(w) = \frac{1}{M} \sum_{m=1}^M \lambda_m \nabla 1 F_m(w, \hat{\beta}_m(w)) + \frac{1}{M} \sum_{m=1}^M \lambda_m \nabla 2 F_m(w, \hat{\beta}_m(w))
\]

(24)

where

\[
\nabla 1 F_m(w, \hat{\beta}_m(w)) := \nabla_w F_m(w, \hat{\beta}_m(w)),
\]

\[
\nabla 2 F_m(w, \hat{\beta}_m(w)) := -\nabla^2_w G_m(w, \hat{\beta}_m(w)) \left[ \nabla^2_{\beta_m \beta_m} G_m(w, \hat{\beta}_m(w)) \right]^{-1} \nabla \beta_m F_m(w, \hat{\beta}_m(w)).
\]

There are two parts to \( \nabla h(w) \) and, therefore, instead of choosing a single subset of clients for computing both parts, we decouple \( S^t \) into two subsets \( S_1^t \) and \( S_2^t \), \( S^t = S_1^t \cup S_2^t \). We use clients in \( S_1^t \) to compute local updates of the first part, and clients in \( S_2^t \) to compute the local updates of the second part. To get an estimate of \( \nabla 1 h(w) \), we can estimate \( \nabla 1 h(w) \) and \( \nabla 2 h(w) \) separably and then combine. Assume that \( g^t_{1,m} \) is an estimate of \( \nabla 1 F_m(w, \hat{\beta}_m(w)) \) and \( g^t_{2,m} \) is an estimate of \( \nabla 2 F_m(w, \hat{\beta}_m(w)) \), we can then construct estimates of \( \nabla 1 h(w) \) and \( \nabla 2 h(w) \) as

\[
g^t_1 = \frac{1}{K_1} \sum_{m \in S_1^t} \lambda_m g^t_{1,m}, \quad g^t_2 = \frac{1}{K_2} \sum_{m \in S_2^t} \lambda_m g^t_{2,m},
\]

where \( K_1 = |S_1^t| \) and \( K_2 = |S_2^t| \). Then \( g^t = g^t_1 + g^t_2 \) is an estimate of \( \nabla h(w) \).

We design \( p_1^t \) and \( p_2^t \) to choose \( S_1^t \) and \( S_2^t \) by minimizing the variance of the gradients. Note that

\[
\min_{p_1^t} \mathbb{E}_{S_1^t} \left[ \left\| g^t_1 - \nabla 1 h(w^t) \right\|^2 \right] + \min_{p_2^t} \mathbb{E}_{S_2^t} \left[ \left\| g^t_2 - \nabla 2 h(w^t) \right\|^2 \right]
\]

\[
\leq \min_{p_1^t = p_2^t = p^t} \mathbb{E}_{S^t} \left[ \left\| g^t_1 - \nabla 1 h(w^t) + g^t_2 - \nabla 2 h(w^t) \right\|^2 \right],
\]

so that the decomposition allows us to better minimize the variance. We term this approach as **doubly variance reduction for personalized Federated Learning**. The first part minimizes the variance of updates to the shared global parameter, when the best local parameters are fixed; and the second part minimizes the variance of updates to local parameters, when the global part is fixed. While these two parts are related, any given machine will have different contributions to these two tasks.

Adaptive-OSMD Sampler can be used to minimize the variance for both parts of the gradient. We note that this is a heuristic approach to solving the client sampling problem.
when minimizing a personalized FL objective. Personalized FL objectives have additional structures that should be used to design more efficient sampling strategies. Furthermore, designing sampling strategies that improve the statistical performance of trained models, rather than improving computational speed, is important in the heterogeneous setting. Addressing these questions is an important area for future research.

9.2 Sampling with Physical Constraint in FL System

In this paper, we assume that all clients are available in each round. However, in practical FL applications, a subset of the clients may be inactive due to physical constraints, thus we have to assign zero probabilities to them. In this section, we propose a simple extension of our proposed sampling method to such case.

Specifically, denote the subset of clients that are active at the beginning of round $t$ as $I_t \subseteq [M]$. If we have $|I_t| \leq K$, we can then use all clients in $I_t$ to make updates in round $t$; otherwise, we would like to choose a smaller subset $S_t \subseteq I_t$ to participate. This can be achieved by rescaling the output sampling distribution of any of our proposed methods, which we denote as $\hat{p}_t$. We let $\tilde{p}_t^m = \hat{p}_t^m / (\sum_{i \in I_t} \hat{p}_t^i)$ and $\tilde{p}_t^m = 0$ for all $m \not\in I_t$. We can then use $\tilde{p}_t^m$ to choose $S_t$ from $I_t$.

However, analyzing such a method in terms of convergence and regret guarantee is highly non-trivial. Typically, for general active clients sequence $\{I_t\}_{t=1}^T$, the optimization algorithms are not guaranteed to converge even if we involve all clients in $I_t$ in each round. This can happen, for example, if a client is active for only once in the whole training process. Thus, to ensure convergence, we need additional assumptions about $\{I_t\}_{t=1}^T$. Moreover, deriving regret bound is also very challenging, as assigning zero probability to any client will make the variance-reduction loss unbounded and thus the regret can be arbitrarily large. To achieve such theoretical result, one may need to appropriately redefine the regret concept. Such an analysis is beyond the scope of this paper and we leave it for future research.

A. Technical proofs

A.1 Proposition 15 and Its Proof

**Proposition 15** Suppose \( \Phi = \Phi_e \) is the unnormalized negative entropy in Algorithm 1. Let

\[
\tilde{p}_{m}^{t+1} = p_{m}^{t} \exp \left\{ \mathcal{N} \left\{ m \in S^t \right\} \frac{\eta a_{m}}{(K^2 \tilde{p}_{m}^{t})^3} \right\}, \quad m \in [M].
\]

Let \( \pi : [M] \mapsto [M] \) be a permutation such that \( \tilde{p}_{\pi(1)}^{t+1} \leq \tilde{p}_{\pi(2)}^{t+1} \leq \cdots \leq \tilde{p}_{\pi(M)}^{t+1} \). Let \( m^{\star} \) be the smallest integer \( m \) such that

\[
\tilde{p}_{\pi(m)}^{t+1} \left( 1 - \frac{m - 1}{M} \alpha \right) > \frac{\alpha}{M} \sum_{j=m}^{M} \tilde{p}_{\pi(j)}^{t+1}.
\]

Then

\[
\hat{p}_{m}^{t+1} = \begin{cases} 
\alpha/M & \text{if } \pi(m) < m^{\star} \\
\left( (1 - ((m^{\star} - 1)/M)\alpha)\tilde{p}_{m}^{t+1} \right) / \left( \sum_{j=m}^{M} \tilde{p}_{\pi(j)}^{t+1} \right) & \text{otherwise.}
\end{cases}
\]

**Proof** First, we show that the solution \( \hat{p}_{m}^{t+1} \) in Step 7 of Algorithm 1 can be found as

\[
\tilde{p}_{m}^{t+1} = \arg \min_{p \in D} \eta \langle p, \nabla \hat{l}_{t}(\hat{p}_{t}^{t}; \hat{p}_{t}^{t}) \rangle + D_{\Phi_{e}}(p \parallel \tilde{p}_{m}^{t}) ,
\]

\[
\hat{p}_{m}^{t+1} = \arg \min_{p \in A} D_{\Phi_{e}}(p \parallel \tilde{p}_{m}^{t+1}).
\]

The optimality condition for \( \tilde{p}_{m}^{t+1} \) implies that

\[
\eta \nabla \hat{l}_{t}(\hat{p}_{t}^{t}; \hat{p}_{t}^{t}) + \nabla \Phi_{e}(\hat{p}_{m}^{t+1}) - \nabla \Phi_{e}(\hat{p}_{t}^{t}) = 0. \tag{25}
\]

By Lemma 18, the optimality condition for \( \hat{p}_{m}^{t+1} \) implies that

\[
\langle p - \hat{p}_{m}^{t+1}, \nabla \Phi_{e}(\hat{p}_{m}^{t+1}) - \nabla \Phi_{e}(\hat{p}_{t}^{t}) \rangle \geq 0, \quad \text{for all } p \in A.
\]

Combining the last two displays, we have

\[
\langle p - \hat{p}_{m}^{t+1}, \eta \nabla \hat{l}_{t}(\hat{p}_{t}^{t}; \hat{p}_{t}^{t}) + \nabla \Phi_{e}(\hat{p}_{m}^{t+1}) - \nabla \Phi_{e}(\hat{p}_{t}^{t}) \rangle \geq 0, \quad \text{for all } p \in A.
\]

By Lemma 18, this is the optimality condition for \( \hat{p}_{m}^{t+1} \) to be the solution in Step 7 of Algorithm 1.

Note that (25) implies that

\[
-\frac{\eta}{K^2} \cdot \frac{\alpha_{m}}{(\tilde{p}_{m}^{t+1})^3} \mathcal{N} \left\{ m \in S^t \right\} + \log(\tilde{p}_{m}^{t+1}) - \log(\hat{p}_{m}^{t}) = 0, \quad m \in [M].
\]

Therefore,

\[
\hat{p}_{m}^{t+1} = \tilde{p}_{m}^{t} \exp \left( \frac{\eta \alpha_{m}}{K^2 (\tilde{p}_{m}^{t})^3} \mathcal{N} \left\{ m \in S^t \right\} \right), \quad m \in [M],
\]

and the final result follows from Lemma 23.
A.2 Proof of Theorem 4

We first state a proposition that will be used to prove Theorem 4. The key difference between Theorem 4 and Proposition 16 is that in Proposition 16 the comparator sequence lies in \( \mathcal{A} \), and, as a result, there is no projection error.

**Proposition 16** Suppose the conditions of Theorem 4 hold. For any comparator sequence \( q^{1:T} \) with \( q^t \in \mathcal{A} \) for all \( t \in [T] \), we have

\[
D\text{-Regret}_{q^{1:T}}(\hat{q}^{1:T}) \leq \frac{D_{\text{max}}}{\eta_1} + \frac{2H}{\eta T} \mathbb{E} \left[ TV(q^{1:T}) \right] + \frac{2}{\rho} \sum_{t=1}^{T} \eta_t \mathbb{E} \left[ Q_t^2 \right].
\]

**Proof** By Lemma 18 and the definition of \( \hat{p}^{t+1} \) in Step 7 of Algorithm 1, we have

\[
\langle \hat{p}^{t+1} - q^t, \nabla \hat{t}(\hat{p}^t; \hat{p}^t) \rangle \leq \frac{1}{\eta_t} \langle \nabla \Phi(p^t) - \nabla \Phi(p^{t+1}), \hat{p}^{t+1} - q^t \rangle. \tag{26}
\]

By the convexity of \( \hat{t}(\cdot; \hat{p}^t) \), we have

\[
\hat{t}(p^t; \hat{p}^t) - \hat{t}(q^t; \hat{p}^t) \leq \langle \nabla \hat{t}(p^t; \hat{p}^t), \hat{p}^t - q^t \rangle = \langle \nabla \hat{t}(p^t; \hat{p}^t), \hat{p}^{t+1} - q^t \rangle + \langle \nabla \hat{t}(\hat{p}^t; \hat{p}^t), \hat{p}^t - \hat{p}^{t+1} \rangle.
\]

Then, by (26), we further have

\[
\hat{t}(\hat{p}^t; \hat{p}^t) - \hat{t}(q^t; \hat{p}^t) \leq \frac{1}{\eta_t} \langle \nabla \Phi(p^t) - \nabla \Phi(p^{t+1}), \hat{p}^{t+1} - q^t \rangle + \langle \nabla \hat{t}(\hat{p}^t; \hat{p}^t), \hat{p}^t - \hat{p}^{t+1} \rangle.
\]

From the definition of \( \mathcal{D} \), we have

\[
D_{\Phi}(x_1 \parallel x_2) = D_{\Phi}(x_3 \parallel x_2) + D_{\Phi}(x_1 \parallel x_3) + \langle \nabla \Phi(x_2) - \nabla \Phi(x_3), x_3 - x_1 \rangle, \quad x_1, x_2, x_3 \in \mathcal{D}.
\]

Then

\[
\hat{t}(\hat{p}^t; \hat{p}^t) - \hat{t}(q^t; \hat{p}^t) \\
\leq \frac{1}{\eta_t} [D_{\Phi}(q^t \parallel \hat{p}^t) - D_{\Phi}(q^t \parallel \hat{p}^{t+1}) - D_{\Phi}(\hat{p}^{t+1} \parallel \hat{p}^t)] + \langle \nabla \hat{t}(\hat{p}^t; \hat{p}^t), \hat{p}^t - \hat{p}^{t+1} \rangle \\
= \frac{1}{\eta_t} [D_{\Phi}(q^t \parallel \hat{p}^t) - D_{\Phi}(q^{t+1} \parallel \hat{p}^{t+1})] + \frac{1}{\eta_t} [D_{\Phi}(q^{t+1} \parallel \hat{p}^{t+1}) - D_{\Phi}(q^t \parallel \hat{p}^{t+1})] \\
- \frac{1}{\eta_t} D_{\Phi}(\hat{p}^{t+1} \parallel \hat{p}^t) + \langle \nabla \hat{t}(\hat{p}^t; \hat{p}^t), \hat{p}^t - \hat{p}^{t+1} \rangle. \tag{27}
\]

We bound the second term in (27) as

\[
D_{\Phi}(q^{t+1} \parallel \hat{p}^{t+1}) - D_{\Phi}(q^t \parallel \hat{p}^{t+1}) = \Phi(q^{t+1}) - \Phi(q^t) - \langle \nabla \Phi(q^{t+1}), q^{t+1} - q^t \rangle \\
\overset{(a)}{\leq} \langle \nabla \Phi(q^{t+1}) - \nabla \Phi(p^{t+1}), q^{t+1} - q^t \rangle \\
\overset{(b)}{\leq} \| \nabla \Phi(q^{t+1}) - \nabla \Phi(p^{t+1}) \|_* \| q^{t+1} - q^t \| \\
\overset{(c)}{\leq} 2H \| q^{t+1} - q^t \|. \tag{28}
\]

41
Since (a) follows from the convexity of $\Phi(\cdot)$, (b) follows from the definition of the dual norm, and (c) follows from the definition of $H$. Since $\Phi(\cdot)$ is $\rho$-strongly convex, we can bound the third and fourth term in (27) as
\[
-\frac{1}{\eta_t} D_\Phi (\hat{p}^{t+1} || \hat{p}^t) + \langle \nabla \hat{l}_t (\hat{p}^t; \hat{p}^t), \hat{p}^t - \hat{p}^{t+1} \rangle \leq \frac{-\rho}{2\eta_t} \||\hat{p}^{t+1} - \hat{p}^t\||^2 + \||\nabla \hat{l}_t (\hat{p}^t; \hat{p}^t)\||_2 \||\hat{p}^t - \hat{p}^{t+1}\||.
\]
Since $ab \leq a^2/(2c) + b^2/2$, $a, b, \epsilon > 0$, we further have
\[
-\frac{1}{\eta_t} D_\Phi (\hat{p}^{t+1} || \hat{p}^t) + \langle \nabla \hat{l}_t (\hat{p}^t; \hat{p}^t), \hat{p}^t - \hat{p}^{t+1} \rangle \leq \frac{2\eta_t}{\rho} \||\nabla \hat{l}_t (\hat{p}^t; \hat{p}^t)\||_2^2 \leq \frac{2\eta_t}{\rho} Q_t^2.
\]
Combining (27)-(29), we have
\[
\hat{l}_t (\hat{p}^t; \hat{p}^t) - \hat{l}_t (q^t; \hat{p}^t) \leq \frac{D_\Phi (q^t || \hat{p}^t)}{\eta_t} - \frac{D_\Phi (q^{t+1} || \hat{p}^{t+1})}{\eta_{t+1}} + 2H \frac{\||q^{t+1} - q^t\||}{\eta_t} + \frac{2}{\rho} \eta_t Q_t^2.
\]
This implies that
\[
\sum_{t=1}^T \hat{l}_t (\hat{p}^t; \hat{p}^t) - \sum_{t=1}^T \hat{l}_t (q^t; \hat{p}^t) \leq \frac{D_\Phi (q^1 || \hat{p}^1)}{\eta_1} - \frac{D_\Phi (q^{T+1} || \hat{p}^{T+1})}{\eta_{T+1}} + 2H \sum_{t=1}^T \frac{\||q^{t+1} - q^t\||}{\eta_t} + \frac{2}{\rho} \sum_{t=1}^T \eta_t Q_t^2
\]
\[
\leq \frac{D_{\max}}{\eta_1} + \frac{2H}{\eta_T} TV (q^{1:T}) + \frac{2}{\rho} \sum_{t=1}^T \eta_t Q_t^2,
\]
since $\hat{p}_1$ is the uniform distribution. Finally, note that
\[
\mathbb{E} \left[ \sum_{t=1}^T \hat{l}_t (\hat{p}^t; \hat{p}^t) - \sum_{t=1}^T \hat{l}_t (q^t; \hat{p}^t) \right] = \sum_{t=1}^T \mathbb{E} \left[ \mathbb{E}_{S_t} \left[ \hat{l}_t (\hat{p}^t; \hat{p}^t) \right] - \mathbb{E}_{S_t} \left[ \hat{l}_t (q^t; \hat{p}^t) \right] \right]
\]
\[
= \sum_{t=1}^T \mathbb{E} \left[ l_t (\hat{p}^t) - l_t (q^t) \right]
\]
\[
= D\text{-Regret}_T (q^{1:T}).
\]
The conclusion follows by taking expectation on both sides of (30).

We are now ready to prove Theorem 4.

**Proof** [Proof of Theorem 4] For any comparator sequence $q^{1:T}$ with $q_t \in \mathcal{P}_{M-1}$, $t \in [T]$, we have
\[
D\text{-Regret}_T (q^{1:T}) = \mathbb{E} \left[ \sum_{t=1}^T l_t (\hat{p}^t) - \sum_{t=1}^T l_t (q^t) + \sum_{t=1}^T l_t (\hat{q}^t) - \sum_{t=1}^T l_t (q^t) \right].
\]
By Proposition 16, we further have that
\[
\mathbb{E} \left[ \sum_{t=1}^{T} l_t(\hat{p}^t) - \sum_{t=1}^{T} l_t(\tilde{q}^t) \right] 
\leq \frac{D_{\max}}{\eta_t} + \frac{2H}{\eta_t} \mathbb{E} \left[ TV \left( q^{1:T} \right) \right] + \frac{2}{\rho} \sum_{t=1}^{T} \eta_t \mathbb{E} \left[ Q_t^2 \right] + \frac{2H}{\eta_t} \mathbb{E} \left[ TV \left( \tilde{q}^{1:T} \right) - TV \left( q^{1:T} \right) \right].
\] (32)

Therefore, to prove Theorem 4, we design a suitable sequence \( \tilde{q}^{1:T} \), where \( \tilde{q}^t \in \mathcal{A} \), and bound the terms \( \sum_{t=1}^{T} l_t(\tilde{q}^t) - \sum_{t=1}^{T} l_t(q^t) \) and \( TV \left( \tilde{q}^{1:T} \right) - TV \left( q^{1:T} \right) \).

We define \( \tilde{q}^t \) as
\[
\tilde{q}_m^t = \begin{cases} 
\alpha/M & \text{if } q_m^t < \alpha/M, \\
q_m^t - \omega(q^t, \alpha) \left( q_m^t - \frac{\alpha}{M} \right) & \text{if } q_m^t \geq \alpha/M,
\end{cases}
\] (33)

where \( \omega(q^t, \alpha) \) is defined in (9). We now show that \( \tilde{q}^t \in \mathcal{A}, t \in [T] \), by showing that \( \tilde{q}_m^t \geq \alpha/M, m \in [M], \) and \( \sum_{m \in [M]} \tilde{q}_m^t = 1 \). For \( m \in [M] \) such that \( q_m^t < \alpha/M \), we have from (33) that \( \tilde{q}_m^t = \alpha/M \). For \( m \in [M] \) such that \( q_m^t \geq \alpha/M \), by (33), we have \( \tilde{q}_m^t - \alpha/M = (1 - \omega(q^t, \alpha)) \left( q_m^t - \alpha/M \right) \). Thus, we proceed to show that \( \omega(q^t, \alpha) \leq 1 \).

Since
\[
1 = \sum_{m=1}^{M} q_m^t \mathbb{1} \left\{ q_m^t < \frac{\alpha}{M} \right\} + \sum_{m=1}^{M} q_m^t \mathbb{1} \left\{ q_m^t \geq \frac{\alpha}{M} \right\} 
\geq \sum_{m=1}^{M} \frac{\alpha}{M} \mathbb{1} \left\{ q_m^t < \frac{\alpha}{M} \right\} + \sum_{m=1}^{M} \frac{\alpha}{M} \mathbb{1} \left\{ q_m^t \geq \frac{\alpha}{M} \right\} = \alpha,
\]
we have
\[
\sum_{m=1}^{M} \left( q_m^t - \frac{\alpha}{M} \right) \mathbb{1} \left\{ q_m^t \geq \frac{\alpha}{M} \right\} \geq \sum_{m=1}^{M} \left( \frac{\alpha}{M} - q_m^t \right) \mathbb{1} \left\{ q_m^t < \frac{\alpha}{M} \right\}.
\]
Therefore, \( 0 \leq \omega(q^t, \alpha) \leq 1 \). Furthermore, \( \omega(q^t, 0) = 1 \) and \( \omega(q^t, 1) = 1 \). Finally, we show that \( \sum_{m=1}^{M} \tilde{q}_m^t = 1 \). By (33) and the definition of \( \omega(q^t, \alpha) \) in (9), we have
\[
\sum_{m=1}^{M} \tilde{q}_m^t = \sum_{m=1}^{M} \frac{\alpha}{M} \mathbb{1} \left\{ q_m^t < \frac{\alpha}{M} \right\} + \sum_{m=1}^{M} q_m^t \mathbb{1} \left\{ q_m^t \geq \frac{\alpha}{M} \right\} 
- \omega(q^t, \alpha) \sum_{m=1}^{M} \left( q_m^t - \frac{\alpha}{M} \right) \mathbb{1} \left\{ q_m^t \geq \frac{\alpha}{M} \right\}
= \sum_{m=1}^{M} \frac{\alpha}{M} \mathbb{1} \left\{ q_m^t < \frac{\alpha}{M} \right\} + \sum_{m=1}^{M} q_m^t \mathbb{1} \left\{ q_m^t \geq \frac{\alpha}{M} \right\} - \sum_{m=1}^{M} \left( \frac{\alpha}{M} - q_m^t \right) \mathbb{1} \left\{ q_m^t < \frac{\alpha}{M} \right\}
= \sum_{m=1}^{M} q_m^t \mathbb{1} \left\{ q_m^t \geq \frac{\alpha}{M} \right\} + \sum_{m=1}^{M} q_m^t \mathbb{1} \left\{ q_m^t < \frac{\alpha}{M} \right\}
= 1.
\]
Therefore, \( q^t \in A \) for any \( t \in [T] \).

We now bound \( \sum_{t=1}^{T} l_t(q^t) - \sum_{t=1}^{T} l_t(q^t) \). When \( q^t_m < \alpha/M \), then \( 1/q^t_m - 1/q^t_m < 0 \); and when \( q^t_m \geq \alpha/M \), then

\[
\frac{1}{q^t_m} - 1 = \frac{1}{q^t_m} \left[ \frac{1}{1 - \omega(q^t, \alpha) \left( 1 - \frac{\alpha}{M q^t_m} \right)} - 1 \right] = \frac{1}{q^t_m} \cdot \frac{\omega(q^t, \alpha) \left( 1 - \frac{\alpha}{M q^t_m} \right)}{1 - \omega(q^t, \alpha) \left( 1 - \frac{\alpha}{M q^t_m} \right)}.
\]

Since

\[
\omega(q^t, \alpha) \left( 1 - \frac{\alpha}{M q^t_m} \right) \leq \omega(q^t, \alpha) \quad \text{and} \quad 1 - \omega(q^t, \alpha) \left( 1 - \frac{\alpha}{M q^t_m} \right) \geq 1 - \omega(q^t, \alpha) + \frac{\omega(q^t, \alpha) \alpha}{M}
\]

as \( q^t_m \leq 1 \), we have

\[
\frac{1}{q^t_m} - 1 \leq \frac{1}{q^t_m} \cdot \frac{\omega(q^t, \alpha)}{1 - \omega(q^t, \alpha) \left( 1 - \frac{\alpha}{M} \right)} = \frac{\phi(q^t, \alpha)}{q^t_m}.
\]

Thus,

\[
\sum_{t=1}^{T} l_t(q^t) - \sum_{t=1}^{T} l_t(q^t) \leq \sum_{t=1}^{T} \sum_{m=1}^{M} a^t_m \left( \frac{1}{q^t_m} - \frac{1}{q^t_m} \right) \leq \sum_{t=1}^{T} \sum_{m=1}^{M} a^t_m \left( \frac{1}{q^t_m} - \frac{1}{q^t_m} \right) \mathbf{1} \left\{ q^t_m \geq \frac{\alpha}{M} \right\} \leq \sum_{t=1}^{T} \phi(q^t, \alpha) \sum_{m=1}^{M} \frac{a^t_m}{q^t_m} \mathbf{1} \left\{ q^t_m \geq \frac{\alpha}{M} \right\} \leq \sum_{t=1}^{T} \phi(q^t, \alpha) M \sum_{m=1}^{M} \frac{a^t_m}{q^t_m} \mathbf{1} \left\{ q^t_m \geq \frac{\alpha}{M} \right\}.
\]

Next, we bound \( TV(\bar{q}^{1:T}) - TV(q^{1:T}) \). Note that

\[
TV(\bar{q}^{1:T}) = \sum_{t=2}^{T} \| \bar{q}^t - \bar{q}^{t-1} \|_1
\]

\[
= \sum_{t=2}^{T} \| \bar{q}^t - q^t + q^t - q^{t-1} + q^{t-1} - \bar{q}^{t-1} \|_1
\]

\[
\leq \sum_{t=2}^{T} \| \bar{q}^t - q^t \|_1 + \sum_{t=2}^{T} \| q^t - q^{t-1} \|_1 + \sum_{t=2}^{T} \| q^{t-1} - \bar{q}^{t-1} \|_1
\]

\[
\leq TV(q^{1:T}) + 2 \sum_{t=1}^{T} \| \bar{q}^t - q^t \|_1.
\]

We now upper bound \( \sum_{t=1}^{T} \| \bar{q}^t - q^t \|_1 \). If \( q^t_m < \alpha/M \), then \( |\bar{q}^t_m - q^t_m| = \alpha/M - q^t_m \). If \( q^t_m \geq \alpha/M \), by (33), we have \( |\bar{q}^t_m - q^t_m| = \omega(q^t, \alpha)(q^t_m - \alpha/M) \). Therefore, recalling the
Adaptive Client Sampling in Federated Learning

definition of \( \psi(q^t, \alpha) \) in (9), we have

\[
\|q^t - q^t\|_1 = \sum_{m=1}^{M} \left( \frac{\alpha}{M} - q^t_m \right) 1 \{ q^t_m < \frac{\alpha}{M} \} + \omega(q^t, \alpha) \sum_{m=1}^{M} \left( q^t_m - \frac{\alpha}{M} \right) 1 \{ q^t_m \geq \frac{\alpha}{M} \}
\]

\[
= 2 \sum_{m=1}^{M} \left( \frac{\alpha}{M} - q^t_m \right) 1 \{ q^t_m < \frac{\alpha}{M} \}
\]

\[
= 2 \psi(q^t, \alpha)
\]

and

\[
\text{TV}(\tilde{q}^{1:T}) - \text{TV}(q^{1:T}) \leq \sum_{t=1}^{T} \psi(q^t, \alpha). \tag{35}
\]

Combining (31), (32), (34), and (35), and taking expectation on both sides, we obtain the result. \( \blacksquare \)

A.3 Corollary 17 and Its proof

**Corollary 17** Suppose conditions of Theorem 1 hold and \( \Phi = \Phi_e \). Then for any comparator sequence \( \{q^{1:T}\} \), we have

\[
D\text{-Regret}_T(q^{1:T}) \leq \frac{\log M}{\eta_1} + \frac{2 \log(M/\alpha)}{\eta_T} \text{TV}(q^{1:T}) + \frac{2M^6}{K^4 \alpha^6} \sum_{t=1}^{T} \eta_t (\bar{a}^t)^2
\]

\[
+ \frac{4H}{\eta_T} \sum_{t=1}^{T} \psi(q^t, \alpha) + \sum_{t=1}^{T} \phi(q^t, \alpha) l_t(q^t),
\]

where \( \bar{a}^t := \max_{1 \leq m \leq M} a^t_m = \max_{1 \leq m \leq M} \lambda^2_m \|g^t_m\|^2 \).

**Proof** When \( \Phi = \Phi_e \), we have \( \rho = 1 \) from Pinsker’s inequality. Furthermore, \( \| \cdot \|_\infty = \| \cdot \|_\alpha = \nabla \Phi_e(p) = (\log p_1, \ldots, \log p_M)^T \), and \( \bar{p}^t \in A = \mathcal{P}_{M-1} \cap [\alpha/M, \infty)^M \), \( t \in [T] \). Then \( Q_t = M^3 \bar{a}^t/(K^2 \alpha^3) \) and \( H = \log(M/\alpha) \) follows by checking the definition. Finally, to show that \( D_{\Phi_e}(q \| p^{\text{unif}}) \leq \log M \) for all \( q \in A \), we note that \( D_{\Phi_e}(q \| p^{\text{unif}}) = \log M + \sum_{m=1}^{M} q_m \log q_m \leq \log M \). \( \blacksquare \)

A.4 Proof of Theorem 7

The proof proceeds in two steps. First, we show that there exists an expert learning rate \( \eta_e \in \mathcal{E} \) such that the regret bound for \( \hat{p}_e^{1:T} \) is close to (12). That is, we show that there exists \( \eta_e \in \mathcal{E} \) such that

\[
\mathbb{E} \left[ \sum_{t=1}^{T} l_t(\hat{p}_e^t, \hat{p}_e^t) - \sum_{t=1}^{T} l_t(p_e^t) \right] \leq \frac{3\sqrt{2M^3} \sqrt{\mathbb{E}[(\bar{a}^t)^2]}}{K^2 \alpha^3} \sqrt{T \log M + 2 \log (M/\alpha) \mathbb{E} [\text{TV}(p^{1:T})]}. \tag{36}
\]
Note that $S^t \sim \hat{p}^t$. Second, we show that the output of meta-algorithm can track the best expert with small regret. That is, we show that

$$
E \left[ \sum_{t=1}^{T} \hat{l}_t(p^*_t; \hat{p}^t) \right] - E \left[ \sum_{t=1}^{T} \hat{l}_t(p^*_e; \hat{p}^t) \right] \leq \frac{M}{\alpha} \sqrt{\frac{T \mathbb{E}[a]^{1}}{8K}} \left( 1 + 2 \log E \right), \quad e \in [E]. \tag{37}
$$

The theorem follows by combining (36) and (37).

We first prove (36). Since $0 \leq E[TV(p^*_1;T)] \leq 2(T - 1)$, we have

$$
\min \mathcal{E} = \frac{K^2 \alpha^3}{M^3 a^1} \sqrt{\frac{\log M}{2T}} \leq \eta^* \leq \frac{K^2 \alpha^3}{M^3 a^1} \sqrt{\frac{\log M + 4 \log (M/\alpha)(T - 1)}{2T}} \leq \max \mathcal{E},
$$

where $\eta^*$ is defined as in (11). Thus, there exists $\eta_e \in \mathcal{E}$, such that $\eta_e \leq \eta^* \leq 2\eta_e$. Repeating the proof of (30) and proof of Corollary 17, we show that

$$
\sum_{t=1}^{T} \hat{l}_t(p^*_e; \hat{p}^t) - \sum_{t=1}^{T} \hat{l}_t(p^*_t; \hat{p}^t) \leq \frac{\log M}{\eta_e} + \frac{2 \log (M/\alpha)}{\eta_e} TV(p^*_1;T) + \frac{2 \eta_e M^6}{K^4 \alpha^6} \sum_{t=1}^{T} (\bar{a}^t)^2,
$$

which then implies that

$$
E \left[ \sum_{t=1}^{T} \hat{l}_t(p^*_e; \hat{p}^t) - \sum_{t=1}^{T} \hat{l}_t(p^*_t; \hat{p}^t) \right] \leq \frac{\log M}{\eta_e} + \frac{2 \log (M/\alpha)}{\eta_e} E \left[ TV(p^*_1;T) \right] + \frac{2 \eta_e M^6}{K^4 \alpha^6} \sum_{t=1}^{T} (\bar{a}^t)^2,
$$

Since $\eta^*/2 \leq \eta_e \leq \eta^*$, we further have

$$
E \left[ \sum_{t=1}^{T} \hat{l}_t(p^*_e; \hat{p}^t) - \sum_{t=1}^{T} \hat{l}_t(p^*_t; \hat{p}^t) \right] \leq \frac{2 \log M}{\eta^*} + \frac{4 \log (M/\alpha)}{\eta^*} E \left[ TV(p^*_1;T) \right] + \frac{2 \eta^* M^6}{K^4 \alpha^6} \sum_{t=1}^{T} (\bar{a}^t)^2
$$

$$
\leq \frac{2 \log M}{\eta^*} + \frac{4 \log (M/\alpha)}{\eta^*} E \left[ TV(p^*_1;T) \right] + \frac{2 \eta^* M^6 T}{K^4 \alpha^6} E \left[ (\bar{a}^t)^2 \right]
$$

$$
= \frac{3 \sqrt{2} M^3 \sqrt{E[(\bar{a}^t)^2]}}{K^2 \alpha^3} \sqrt{T \log M + 2 \log (M/\alpha) E[TV(p^*_1;T)]}.
$$

Now, (36) follows, since

$$
E \left[ \sum_{t=1}^{T} \hat{l}_t(p^*_e; \hat{p}^t) \right] = \sum_{t=1}^{T} E \left[ \mathbb{E}_{\eta_t} \left[ \hat{l}_t(p^*_t; \hat{p}^t) \right] \right] = \sum_{t=1}^{T} E \left[ \hat{l}_t(p^*_e) \right].
$$

We prove (37) next. Let

$$
\hat{L}^e_t = \sum_{s=1}^{t} \hat{l}_s(p^*_e; \hat{p}^s) \quad e \in [E], t \in [T].
$$
Recall the update for $\theta^t_e$ in Step 11 of Alg 3. We have

$$
\theta^t_e = \frac{\theta^1_e \exp \left(-\gamma \hat{L}^t_{t-1}\right)}{\sum_{b=1}^{E} \theta^1_b \exp \left(-\gamma \hat{L}^b_{t-1}\right)}, \quad t = 2, \ldots T.
$$

Let $\Theta_t = \sum_{b=1}^{E} \theta^1_b \exp \left\{-\gamma \hat{L}^b_{t}\right\}$. Then

$$
\log \Theta_1 = \log \left(\sum_{b=1}^{E} \theta^1_b \exp \left\{-\gamma \hat{L}^b_{1}\right\}\right)
$$

and, for $t \geq 2$,

$$
\log \left(\frac{\Theta_t}{\Theta_{t-1}}\right) = \log \left(\frac{\sum_{b=1}^{E} \theta^1_b \exp \left\{-\gamma \hat{L}^b_{t-1}\right\} \exp \left\{-\gamma \hat{L}_t (\hat{p}^t_b; \hat{p}^t)\right\}}{\sum_{b=1}^{E} \theta^1_b \exp \left\{-\gamma \hat{L}^b_{t-1}\right\}}\right) = \log \left(\sum_{b=1}^{E} \theta^1_b \exp \left\{-\gamma \hat{L}_t (\hat{p}^t_b; \hat{p}^t)\right\}\right).
$$

We have

$$
\log \Theta_T = \log \Theta_1 + \sum_{t=1}^{T} \log \left(\frac{\Theta_t}{\Theta_{t-1}}\right)
$$

$$
= \sum_{t=1}^{T} \log \left(\sum_{b=1}^{E} \theta^1_b \exp \left\{-\gamma \hat{L}_t (\hat{p}^t_b; \hat{p}^t)\right\}\right)
$$

$$
\leq \sum_{t=1}^{T} \left(-\gamma \sum_{b=1}^{E} \theta^1_b \hat{L}_t (\hat{p}^t_b; \hat{p}^t) + \frac{\gamma^2 M^2 \bar{a}^t}{8K\alpha^2}\right) \quad \text{(Lemma 22)}
$$

$$
\leq -\gamma \sum_{t=1}^{T} \hat{L}_t (\hat{p}^t; \hat{p}^t) + \frac{\gamma^2 M^2 \left(\sum_{t=1}^{T} \bar{a}^t\right)}{8K\alpha^2} \quad \text{(Jensen’s inequality)}
$$

and

$$
\log (\Theta_T) = \log \left(\sum_{b=1}^{E} \theta^1_b \exp \left\{-\gamma \hat{L}^b_T\right\}\right)
$$

$$
\geq \log \left(\max_{1 \leq b \leq E} \theta^1_b \exp \left\{-\gamma \hat{L}^b_T\right\}\right) = -\gamma \min_{1 \leq b \leq E} \left\{\hat{L}^b_T + \frac{1}{\gamma} \log \frac{1}{\theta^1_b}\right\}.
$$

Combining the last two displays, we have

$$
-\gamma \min_{1 \leq b \leq E} \left\{\hat{L}^b_T + \frac{1}{\gamma} \log \frac{1}{\theta^1_b}\right\} \leq -\gamma \sum_{t=1}^{T} \hat{L}_t (\hat{p}^t; \hat{p}^t) + \frac{\gamma^2 M^2 \left(\sum_{t=1}^{T} \bar{a}^t\right)}{8K\alpha^2},
$$

47
which implies that
\[
\sum_{t=1}^{T} \hat{l}_t(p_t^i; \hat{p}_t^i) - \hat{L}_T^e \leq \frac{\gamma M^2 \left( \frac{1}{\gamma} \log \frac{1}{\theta^t_e} \right)}{8K\alpha^2} + \frac{1}{\gamma} \log \frac{1}{\theta^t_e} \leq \frac{\gamma M^2 T \alpha^1}{8K\alpha^2} + \frac{1}{\gamma} \log \frac{1}{\theta^t_e}, \quad e \in [E].
\]

Taking expectation on both sides, we then have
\[
\mathbb{E} \left[ \sum_{t=1}^{T} \hat{l}_t(p_t^i; \hat{p}_t^i) - \hat{L}_T^e \right] \leq \frac{\gamma M^2 T \mathbb{E} [\hat{a}_t^1]}{8K\alpha^2} + \frac{1}{\gamma} \log \frac{1}{\theta^t_e}.
\]

Since \( \theta^t_e \geq \frac{1}{E^2} \), \( \log 1/\theta^t_e \leq 2 \log E \). Let \( \gamma = \sqrt{8K\alpha^2/(T M^2 \mathbb{E}[\hat{a}_t^1])} \) to minimize the right hand side of the above inequality with \( \log 1/\theta^t_e \) substituted by 1. Then
\[
\mathbb{E} \left[ \sum_{t=1}^{T} \hat{l}_t(p_t^i; \hat{p}_t^i) - \hat{L}_T^e \right] = \mathbb{E} \left[ \sum_{t=1}^{T} \hat{l}_t(p_t^i; \hat{p}_t^i) - \sum_{t=1}^{T} \hat{l}_t(p_t^i; \hat{p}_t^i) \right] 
\leq M \alpha \sqrt{\frac{T \mathbb{E} [\hat{a}_t^1]}{8K} (1 + 2 \log E), \quad e \in [E].
\]

### A.5 Proof of Theorem 8

Recall that \( T_b = 2^{b-1} \) and \( \hat{p}_b \) is reinitialized as the uniform distribution. Let
\[
\text{D-Regret}_b = \mathbb{E} \left[ \sum_{t=T_b}^{T_b+1} l_t(\hat{p}_t) - \sum_{t=T_b}^{T_b+1} l_t(p_t^b) \right].
\]

Similar to the proof of (36) and (37), we have
\[
\text{D-Regret}_b \leq \frac{(2C + 1)\sqrt{2} M^3 \sqrt{\mathbb{E} [(\hat{a}_T^b)^2]}}{K^2\alpha^3} \sqrt{\log M + 2 \log (M/\alpha) \mathbb{E} [\text{TV} (p_T^{T_b+1-(T_b+1)})]} (T_b+1 - T_b)
\]
\[
+ \frac{M}{\alpha} \sqrt{\frac{(T_b+1 - T_b) \mathbb{E} [\hat{a}_T^b]}{8K}} (C + 2 \log E_b)
\]
\[
\leq \frac{(2C + 1)\sqrt{2} M^3 \sqrt{\mathbb{E} [(\hat{a}_T^b)^2]}}{K^2\alpha^3} \sqrt{\log M + 2 \log (M/\alpha) \mathbb{E} [\text{TV} (p_T^1:T)]} (\sqrt{2})^{b-1}
\]
\[
+ \frac{M}{\alpha} \sqrt{\frac{\mathbb{E} [\hat{a}_T^b]}{8K}} (C + 2 \log E) (\sqrt{2})^{b-1},
\]

where \( E \) is defined in (14). Since \( B = \lceil \log_2 (T + 1) \rceil \), we have \( T_B \leq T \leq T_{B+1} - 1 \), which implies that \( 1 \leq T - T_B + 1 \leq T_{B+1} - T_B = 2^{B} \). Thus, we can similarly obtain
\[
\mathbb{E} \left[ \sum_{t=T_B}^{T} l_t(\hat{p}_t) - \sum_{t=T_B}^{T} l_t(p_t^b) \right] \leq \frac{(2C + 1)\sqrt{2} M^3 \sqrt{\mathbb{E} [(\hat{a}_T^b)^2]}}{K^2\alpha^3} \sqrt{\log M + 2 \log (M/\alpha) \mathbb{E} [\text{TV} (p_T^1:T)]} (\sqrt{2})^B
\]

48
Since

Besides, we let which is drawn from \([M]\) from the comparator sampling distribution. The ghost subset is only constructed for theoretical purpose and does not need to be computed in practice. We only show the result follows combing the last two displays.

\[ E \left[ g^t \mid w^t, \hat{p}^t \right] = \nabla F(w^t), \] thus we have \( E \left[ \delta^t \mid w^t, \hat{p}^t \right] = 0, \) and

\[ E \left[ \langle \nabla F(w^t), \delta^t \rangle \right] = E \left[ E \left[ \langle \nabla F(w^t), \delta^t \rangle \mid w^t, \hat{p}^t \right] \right] = 0. \tag{39} \]

On the other hand, we can assume that there is a ghost subset of clients \( \tilde{S}^t \) with \( |\tilde{S}^t| = K, \) which is drawn from \([M]\) with sampling distribution \( q_* \). Recall that \( J^t = (1/M) \sum_{m=1}^M g^t_m. \) Besides, we let

\[ \hat{g}^t := \frac{1}{MK} \sum_{m \in \tilde{S}^t} g^t_m. \]

Then we have

\[ E_{\tilde{S}^t} \left[ \| \delta^t \|^2 \mid w^t, \hat{p}^t \right] = E_{\tilde{S}^t} \left[ \| g^t - J^t + J^t - \nabla F(w^t) \|^2 \mid w^t, \hat{p}^t \right] \\
= E_{\tilde{S}^t} \left[ \| g^t - J^t \|^2 \mid w^t, \hat{p}^t \right] + \| J^t - \nabla F(w^t) \|^2 \\
= l_t (\hat{p}^t) - \| J^t \|^2 + \| J^t - \nabla F(w^t) \|^2 \\
= l_t (q_*) - \| J^t \|^2 + \| J^t - \nabla F(w^t) \|^2 + l_t (\hat{p}^t) - l_t (q_*) \]

Since

\[ E \left[ \| \hat{g}^t - \nabla F(w^t) \|^2 \mid w^t, \hat{p}^t \right] \]

\[ + \frac{M}{\alpha} \sqrt{\frac{E [\hat{a}^t]}{8K}} (C + 2 \log E)(\sqrt{2})^B. \]
\[
\begin{align*}
&= \mathbb{E} \left[ \left\| \frac{1}{MK} \sum_{m \in S^t} \frac{g_m^t}{q_m^*} - \nabla F(w^t) \right\|^2 | w^t, \hat{p}^t \right] \\
&\leq 2 \mathbb{E} \left[ \left\| \frac{1}{MK} \sum_{m \in S^t} \frac{g_m^t}{q_m^*} - \frac{1}{MK} \sum_{m \in S^t} \nabla F_m(w^t) \right\|^2 | w^t, \hat{p}^t \right] \\
&+ 2 \mathbb{E} \left[ \left\| \frac{1}{MK} \sum_{m \in S^t} \nabla F_m(w^t) - \nabla F(w^t) \right\|^2 | w^t, \hat{p}^t \right] \\
&= \frac{2}{M^2 K^2} \mathbb{E} \left[ \sum_{m \in S^t} \mathbb{E} \left[ \left\| \frac{g_m^t - \nabla F_m(w^t)}{q_m^*} \right\|^2 \right] | w^t, \hat{p}^t \right] \\
&+ \frac{2}{K} \left( \frac{1}{M^2} \sum_{m=1}^M \left\| \frac{\nabla F_m(w^t)}{q_m^*} \right\|^2 - \left\| \nabla F(w^t) \right\|^2 \right) \\
&\leq \frac{2\sigma^2}{M^2 KB \mu} \sum_{m=1}^M \frac{1}{q_m^*} + \frac{2\zeta_1^2}{K} \leq \frac{2\sigma^2}{KB \mu} + \frac{2\zeta_1^2}{K},
\end{align*}
\]

where the penultimate line follows that \( \mathbb{E} \left[ \left\| \frac{g_m^t - \nabla F_m(w^t)}{q_m^*} \right\|^2 \right] \leq \sigma^2/B \) and the definition of \( \zeta_1 \), and the last line follows that \( q_m^* \geq M \).

Thus, we have
\[
\mathbb{E} \left[ \left\| \delta^t \right\|^2 | w^t, \hat{p}^t \right] \leq \frac{2\sigma^2}{KB \mu} + \frac{2\zeta_1^2}{K} + L_t (\hat{p}^t) - L_t (q^*),
\]

which implies that
\[
\sum_{t=0}^{T-1} \mathbb{E} \left[ \left\| \delta^t \right\|^2 \right] \leq \frac{2T\sigma^2}{KB \mu} + \frac{2T\zeta_1^2}{K} + \mathbb{E} \left[ \sum_{t=0}^{T-1} l_t (\hat{p}^t) - \sum_{t=0}^{T-1} l_t (q^*) \right] \\
= \frac{2T\sigma^2}{KB \mu} + \frac{2T\zeta_1^2}{K} + \text{D-Regret}_{T}(q^*). \quad (40)
\]

Combine (38), (39) and (40), we have
\[
\left( \mu - \frac{L}{2} \mu^2 \right) \sum_{t=0}^{T-1} \mathbb{E} \left[ \left\| \nabla F (w^t) \right\|^2 \right] \leq F(w^1) - F(w^T) + \frac{L}{2} \mu^2 \left( \frac{2T\sigma^2}{KB \mu} + \frac{2T\zeta_1^2}{K} + \text{D-Regret}_{T}(q^*) \right) \leq DF + \frac{L}{2} \mu^2 \left( \frac{2T\sigma^2}{KB \mu} + \frac{2T\zeta_1^2}{K} + \text{D-Regret}_{T}(q^*) \right).
\]

Since \( \mu \leq 1/L \), thus \( \mu - \frac{L}{2} \mu^2 = \mu (1 - \frac{L}{2} \mu) \geq \mu/2 \), thus
\[
\frac{1}{T} \sum_{t=0}^{T-1} \mathbb{E} \left[ \left\| \nabla F (w^t) \right\|^2 \right] \leq \frac{2DF}{T \mu} + L \mu \left( \frac{2\sigma^2}{KB \mu} + \frac{2\zeta_1^2}{K} + \frac{\text{D-Regret}_{T}(q^*)}{T} \right).
\]
Finally, let
\[
\mu = \min \left\{ 1/L, (1/\sigma) \sqrt{D^F K B \alpha / (LT)}, (1/\zeta_1) \sqrt{D^F K / (TL)}, \sqrt{D^F / (L D \text{Regret}_T(q^*))} \right\},
\]
then we have
\[
\frac{1}{T} \sum_{t=0}^{T-1} \mathbb{E} \left[ \| \nabla F(w^t) \|^2 \right] \leq \frac{D^F}{T} \max \left\{ L, \sigma \sqrt{\frac{LT}{D^F K B \alpha}}, \zeta_1 \sqrt{\frac{TL}{D^F K}}, \sqrt{\frac{L \text{Regret}_T(q^*)}{D^F}} \right\} + \sigma \sqrt{\frac{D^F L}{TK B \alpha}} + \zeta_1 \sqrt{\frac{D^F L}{TK}} + \sqrt{\frac{D^F L \text{Regret}_T(q^*)}{T}}.
\]

A.7 Proof of Theorem 14

Similar to the proof in Appendix A.6, the key novel technique is the construction of a ghost subset that is drawn from \([M]\) by the comparator sampling distribution. The ghost subset is only constructed for theoretical purpose and does not need to be computed in practice. We only show the proof of \(R_1, R_0\) and \(R_2\) can be then derived in a similar fashion.

By Assumption 10 and Lemma 19, we have
\[
F(w^{t+1}) \leq F(w^t) + \langle -\nabla F(w^t), w^{t+1} - w^t \rangle + \frac{L}{2} \| w^{t+1} - w^t \|^2,
\]
where
\[
w^{t+1} - w^t = -\frac{\mu}{MK} \sum_{m \in S^t} \frac{1}{\tilde{p}_m} g^t_m, \quad g^t_m = \mu \sum_{b=0}^{B-1} \nabla \phi(w^{t,b}_m; \xi_m^t, \xi_m^b).
\]
Let \(B_m^t = \{ \xi_m^0, \ldots, \xi_m^{B-1} \} \) and \(\mathbb{E}_{S^t} [\cdot]\) denote the expectation with respect to \(S^t\). We then have
\[
\mathbb{E}_{S^t} [F(w^{t+1})] \leq F(w^t) - \mu \langle \nabla F(w^t), \frac{1}{M} \sum_{m=1}^{M} g^t_m \rangle + \frac{L \mu^2}{2} \mathbb{E}_{S^t} \left[ \left\| \frac{1}{K} \sum_{m \in S^t} \frac{1}{\tilde{p}_m} g^t_m \right\|^2 \right].
\]
Recall that $J^t = (1/M) \sum_{m=1}^{M} g_m^t$, then we have
\[
\mathbb{E}_{S^t} \left[ F \left( w^{t+1} \right) \right] \leq F \left( w^t \right) - \mu \left\langle \nabla F \left( w^t \right), J^t \right\rangle + \frac{L\mu^2}{2} \mathbb{E}_{S^t} \left[ \left\| \frac{1}{K} \sum_{m \in S^t} \frac{1}{M_{\hat{p}_m}} g_m^t - J^t \right\|^2 \right]
\]
\[
= F \left( w^t \right) - \mu \left\langle \nabla F \left( w^t \right), J^t \right\rangle + \frac{L\mu^2}{2} \left\| J^t \right\|^2 + \frac{L\mu^2}{2} \mathbb{E}_{S^t} \left[ \left\| \frac{1}{K} \sum_{m \in S^t} \frac{1}{M_{\hat{p}_m}} g_m^t - J^t \right\|^2 \right].
\]

Recall that in Algorithm 7, we let $a_m^t = \frac{\left\| g_m^t \right\|^2}{B(M\mu)^2}$, thus we have
\[
\mathbb{E}_{S^t} \left[ \left\| \frac{1}{K} \sum_{m \in S^t} \frac{1}{M_{\hat{p}_m}} g_m^t - J^t \right\|^2 \right] = \frac{1}{K} \sum_{m=1}^{M} \frac{\left\| g_m^t \right\|^2}{M^2\hat{p}_m^2} - \frac{1}{K} \left\| J^t \right\|^2
\]
\[
= B\mu_l^2 \frac{1}{K} \sum_{m=1}^{M} \frac{\left\| g_m^t \right\|^2}{B(\mu_l M)^2\hat{p}_m^2} - \frac{1}{K} \left\| J^t \right\|^2
\]
\[
= B\mu_l^2 \frac{1}{K} \sum_{m=1}^{M} \frac{a_m^t}{\hat{p}_m^2} - \frac{1}{K} \left\| J^t \right\|^2
\]
\[
= B\mu_l^2 \bar{l}_t (\hat{p}^t) - \frac{1}{K} \left\| J^t \right\|^2,
\]
which then implies that
\[
\mathbb{E}_{S^t} \left[ F \left( w^{t+1} \right) \right] \leq F \left( w^t \right) - \mu \left\langle \nabla F \left( w^t \right), J^t \right\rangle + \frac{L\mu^2}{2} \left\| J^t \right\|^2 + \frac{B\mu^2}{2} \left( l_t(q^*) - \frac{1}{K} \left\| J^t \right\|^2 \right),
\]
where $l_t(q)$ is the variance reduction loss defined in (4).

We assume that there is a ghost subset of clients $S^t$ with $|\tilde{S}^t| = K$, which is drawn from $[M]$ with sampling distribution $q_*$. Besides, we let
\[
\tilde{g}^t := \frac{1}{K} \sum_{m \in S^t} g_m^t / M q_m^*,
\]
then we have
\[
\mathbb{E}_{\tilde{S}^t} \left[ \left\| \tilde{g}^t - J^t \right\|^2 \right] = \bar{l}_t(q^*) - \frac{1}{K} \left\| J^t \right\|^2.
\]
Combine the above equation with (42), we have
\[
\mathbb{E}_{\tilde{S}^t} \left[ F \left( w^{t+1} \right) \right] \leq F \left( w^t \right) - \mu \left\langle \nabla F \left( w^t \right), J^t \right\rangle + \frac{L\mu^2}{2} \left\| J^t \right\|^2 + \frac{L\mu^2}{2} \left( \bar{l}_t(q^*) - \frac{1}{K} \left\| J^t \right\|^2 \right)
\]
\[
+ \frac{L\mu^2}{2} \left( l_t(\hat{p}^t) - l_t(q^*) \right)
\]
\[
= F \left( w^t \right) - \mu \left\langle \nabla F \left( w^t \right), J^t \right\rangle + \frac{L\mu^2}{2} \left\| J^t \right\|^2 + \frac{B\mu^2}{2} \left( l_t(\hat{p}^t) - l_t(q^*) \right)
\]
52
Let \( E_t[\cdot] \) denote the expectation conditioned on \( w^t \). We thus have

\[
E_t \left[ F(w^{t+1}) \right] \leq F(w^t) - \frac{\mu L}{M} E_t \left[ \langle \nabla F(w^t), \sum_{m=1}^{M} \sum_{b=0}^{B-1} \nabla F_m(w_{m,b}^t) \rangle \right] + \frac{L \mu^2}{2} E_t \left[ \| \hat{g}^t \|^2 \right] + \frac{L \mu^2}{2} E_t \left[ l_t(\hat{p}^t) - l_t(q^*) \right].
\]

(43)

Note that for any \( u, v \in \mathbb{R}^d \), we have \(-\langle u, v \rangle = -\frac{1}{2} \| u \|^2 + \frac{1}{2} \| u - v \|^2 \leq -\frac{1}{2} \| u \|^2 + \frac{1}{2} \| u - v \|^2\). Thus we have

\[
E_t \left[ -\frac{\mu L B}{2} \| \nabla F(w^t) \|^2 + \frac{\mu B}{2} \sum_{b=0}^{B-1} \left\| \frac{1}{M} \sum_{m=1}^{M} \left( \nabla F_m(w^t) - \nabla F_m(w_{m,b}^t) \right) \right\|^2 \right]
\]

\[
= -\frac{\mu L B}{2} \| \nabla F(w^t) \|^2 + \frac{\mu L B}{2} \sum_{b=0}^{B-1} \left\| \frac{1}{M} \sum_{m=1}^{M} \sum_{b=0}^{B-1} \nabla F_m(w^t) - \nabla F_m(w_{m,b}^t) \right\|^2 
\]

\[
\leq -\frac{\mu L B}{2} \| \nabla F(w^t) \|^2 + \frac{\mu L B}{2} \sum_{b=0}^{B-1} \left\| \frac{1}{M} \sum_{m=1}^{M} \sum_{b=0}^{B-1} \nabla F_m(w^t) - \nabla F_m(w_{m,b}^t) \right\|^2 
\]

\[
\leq -\frac{\mu L B}{2} \| \nabla F(w^t) \|^2 + \frac{\mu L B}{2} \sum_{b=0}^{B-1} \left\| \frac{1}{M} \sum_{m=1}^{M} \sum_{b=0}^{B-1} \nabla F_m(w^t) - \nabla F_m(w_{m,b}^t) \right\|^2 
\]

\[
\leq -\frac{\mu L B}{2} \| \nabla F(w^t) \|^2 \quad \text{and} \quad \frac{\mu L B}{2} \sum_{b=0}^{B-1} \left\| \frac{1}{M} \sum_{m=1}^{M} \sum_{b=0}^{B-1} \nabla F_m(w^t) - \nabla F_m(w_{m,b}^t) \right\|^2 
\]

(44)

Besides, we also have

\[
E_t \left[ \| \hat{g}^t \|^2 \right] = E_t \left[ \left\| \frac{1}{K} \sum_{m \in S^t} \frac{g_m^t}{M q_m^t} \right\|^2 \right] = \mu^2 \sum_{m \in S^t} \left\| \frac{1}{M q_m^t} \sum_{b=0}^{B-1} \nabla \phi(w_{m,b}, \xi_{m,b}) \right\|^2 
\]

\[
= \mu^2 \sum_{m \in S^t} \left\| \frac{1}{M q_m^t} \sum_{b=0}^{B-1} \nabla \phi(w_{m,b}, \xi_{m,b}) + \nabla F_m(w_{m,b}) \right\|^2 
\]

\[
+ \mu^2 \sum_{m \in S^t} \left\| \frac{1}{M q_m^t} \sum_{b=0}^{B-1} \nabla F_m(w_{m,b}) \right\|^2 
\]

(45)
To bound $I_1$, note that
\[
I_1 = \frac{1}{K} \sum_{m=1}^{M} \frac{1}{M^2q_m^*} \mathbb{E}_t \left[ \left\| \sum_{b=0}^{B-1} \nabla \phi(w_{m}^{t,b}; \xi_{m}^{t,b}) - \nabla F_m(w^{t,b}) \right\|^2 \right]
\]
\[
= \frac{1}{K} \sum_{m=1}^{M} \frac{1}{M^2q_m^*} \sum_{b=0}^{B-1} \mathbb{E}_t \left[ \left\| \nabla \phi(w_{m}^{t,b}; \xi_{m}^{t,b}) - \nabla F_m(w^{t,b}) \right\|^2 \right]
\]
\[
\leq \frac{\sigma^2B}{M^2K} \sum_{m=1}^{M} \frac{1}{q_m^*}.
\]
Since we have $q_m^* \geq \alpha/M$, we then have
\[
I_1 \leq \frac{\sigma^2B}{K\alpha}.
\] (46)

We then give an upper bound on $I_2$. Note that
\[
I_2 = \mathbb{E}_t \left[ \left\| \sum_{m \in S^t} \frac{1}{Mq_m^*} \sum_{b=0}^{B-1} \left( \nabla F_m(w_{m}^{t,b}) - \nabla F_m(w^t) \right) \right\|^2 \right]
\]
\[
\leq 2\mathbb{E}_t \left[ \left\| \sum_{m \in S^t} \frac{1}{Mq_m^*} \sum_{b=0}^{B-1} \left( \nabla F_m(w_{m}^{t,b}) - \nabla F_m(w^t) \right) \right\|^2 \right]
\]
\[
+ 2B^2\mathbb{E}_t \left[ \left\| \sum_{m \in S^t} \frac{1}{Mq_m^*} \nabla F_m(w^t) \right\|^2 \right]
\]
\[
\leq 2\mathbb{E}_t \left[ \left\| \sum_{m \in S^t} \frac{1}{Mq_m^*} \sum_{b=0}^{B-1} \left( \nabla F_m(w_{m}^{t,b}) - \nabla F_m(w^t) \right) \right\|^2 \right]
\]
\[
+ 2B^2\mathbb{E}_t \left[ \left\| \sum_{m \in S^t} \frac{1}{Mq_m^*} \nabla F_m(w^t) \right\|^2 \right]
\]
\[
= 2\mathbb{E}_t \left[ \sum_{m=1}^{M} \frac{1}{M^2q_m^*} \left\| \sum_{b=0}^{B-1} \left( \nabla F_m(w_{m}^{t,b}) - \nabla F_m(w^t) \right) \right\|^2 \right]
\]
\[
+ 2B^2\mathbb{E}_t \left[ \left\| \sum_{m \in S^t} \frac{1}{Mq_m^*} \nabla F_m(w^t) \right\|^2 \right] + 2B^2 \left\| \nabla F(w^t) \right\|^2
\]
\[
\leq 2B\mathbb{E}_t \left[ \sum_{m=1}^{M} \frac{1}{M^2q_m^*} \left\| \sum_{b=0}^{B-1} \left( \nabla F_m(w_{m}^{t,b}) - \nabla F_m(w^t) \right) \right\|^2 \right]
\]
\[
+ 2B^2\mathbb{E}_t \left[ \left\| \sum_{m \in S^t} \frac{1}{Mq_m^*} \nabla F_m(w^t) \right\|^2 \right] + 2B^2 \left\| \nabla F(w^t) \right\|^2
\]
\[
+ 2B^2 \left( \frac{1}{M^2} \sum_{m=1}^{M} \frac{1}{q_m^*} \left\| \nabla F_m(w^t) \right\|^2 - \left\| \nabla F(w^t) \right\|^2 \right)
\]
By letting \( \tilde{\zeta} \) equality follows the definition of \( \zeta_1^2 \) in (17) and the definition of \( q^* \) in (18), and the final inequality follows Assumption 10. Finally, since \( q_m^* \geq \alpha/M \), we have

\[
I_2 \leq \frac{2BL^2}{M\alpha} \mathbb{E}_t \left[ \sum_{m=1}^{M} \sum_{b=0}^{B-1} \left\| w_{m}^{t,b} - w^t \right\|^2 \right] + 2B^2 \left\| \nabla F(w^t) \right\|^2 + \frac{2B^2\zeta_1^2}{K},
\]

where the first three inequalities follow Jensen’s inequality and Lemma 20, the fourth inequality follows Assumption 20, and the final inequality follows Assumption 10. Finally, since \( q_m^* \geq \alpha/M \), we have

\[
I_2 \leq \frac{2BL^2}{M\alpha} \mathbb{E}_t \left[ \sum_{m=1}^{M} \sum_{b=0}^{B-1} \left\| w_{m}^{t,b} - w^t \right\|^2 \right] + 2B^2 \left\| \nabla F(w^t) \right\|^2 + \frac{2B^2\zeta_1^2}{K}.
\]

Combine (45)–(48), we then have

\[
\frac{L\mu^2}{2} \mathbb{E}_t \left[ \left\| \tilde{g}^t \right\|^2 \right] \leq \frac{\mu \mu_B^2 L^2 \sigma^2 B}{2K\alpha} + \frac{\mu \mu_B^2 L^3 B}{M\alpha} \mathbb{E}_t \left[ \sum_{m=1}^{M} \sum_{b=0}^{B-1} \left\| w_{m}^{t,b} - w^t \right\|^2 \right] + \mu \mu_B^2 B^2 L \left\| \nabla F(w^t) \right\|^2 + \frac{\mu \mu_B^2 L^2 B^2 \zeta_1^2}{K}.
\]

Combine the above equation with (43) and (44), we have

\[
\mathbb{E}_t \left[ F(w^{t+1}) \right] \leq F(w^t) - \frac{\mu \mu_B}{2} \left( 1 - 2\mu \mu_B L \right) \left\| \nabla F(w^t) \right\|^2
\]

\[
+ \frac{\mu \mu_B^2 L^2}{M} \left( \frac{1}{2} + \frac{\mu \mu_B L}{\alpha} \right) \mathbb{E}_t \left[ \sum_{m=1}^{M} \sum_{b=0}^{B-1} \left\| w_{m}^{t,b} - w^t \right\|^2 \right]
\]

\[
+ \frac{\mu \mu_B^2 L^3 B^2}{2K\alpha} + \frac{\mu \mu_B^2 L^2 \zeta_1^2}{K} + \frac{BL\mu_B^2 L^2}{2} \mathbb{E}_t \left[ l_t(\hat{p}^t) - l_t(q^*) \right].
\]

By letting \( \tilde{\mu} = \mu \mu_B \) and \( \tilde{\mu} \leq \frac{1}{4BL} \), we have

\[
\mathbb{E}_t \left[ F(w^{t+1}) \right] \leq F(w^t) - \frac{\tilde{\mu} B}{4} \left\| \nabla F(w^t) \right\|^2
\]

\[
+ \frac{\tilde{\mu} L^2}{2} \left( \frac{1}{2} + \frac{1}{4\alpha} \right) \mathbb{E}_t \left[ \frac{1}{M} \sum_{m=1}^{M} \sum_{b=0}^{B-1} \left\| w_{m}^{t,b} - w^t \right\|^2 \right]
\]

\[
+ \frac{\tilde{\mu}^2 B^2 L \sigma^2}{2K\alpha} + \frac{\tilde{\mu}^2 B^2 \zeta_1^2}{K} + \frac{BL\mu_B^2 L^2}{2} \mathbb{E}_t \left[ l_t(\hat{p}^t) - l_t(q^*) \right].
\]

Following Lemma 8 of Karimireddy et al. (2020b), we then show the following claim

\[
\mathbb{E}_t \left[ \frac{1}{M} \sum_{m=1}^{M} \sum_{b=0}^{B-1} \left\| w_{m}^{t,b} - w^t \right\|^2 \right] \leq 4B^3 \mu_B^2 \zeta_0^2 + 4B^3 \mu_B^2 \left\| \nabla F(w^t) \right\|^2 + 2B^2 \mu_B^2 \sigma^2.
\]
To show the above inequality, first note that when $b = 0$, we have $w_{m}^{t,b} = w^t$, thus we have $E_t[\|w_{m}^{t,0} - w^t\|^2] = 0$. Besides, for $b \geq 1$, we have

\[
E_t\left[\|w_{m}^{t,b} - w^t\|^2\right] = E_t\left[\|w_{m}^{t,b-1} - \mu_t \nabla f \left(w_{m}^{t,b-1}; \xi_{m}^{t,b-1}\right) - w^t\|^2\right] = E_t\left[\|w_{m}^{t,b-1} - \mu_t \nabla F_m (w_{m}^{t,b-1}) - w^t\|^2\right]
\]

\[
+ \mu_t^2 E_t \left[\|\nabla f \left(w_{m}^{t,b-1}; \xi_{m}^{t,b-1}\right) - \nabla F_m \left(w_{m}^{t,b-1}\right)\|^2\right]
\]

\[
\leq \left(1 - \frac{1}{B - 1}\right) E_t \left[\|w_{m}^{t,b-1} - w^t\|^2\right] + B \mu_t^2 E_t \left[\|\nabla F_m (w_{m}^{t,b-1})\|^2\right] + \mu_t^2 \sigma^2
\]

\[
\leq \left(1 - \frac{1}{B - 1}\right) E_t \left[\|w_{m}^{t,b-1} - w^t\|^2\right] + 2 \mu_t^2 \|\nabla F_m (w^t)\|^2 + \mu_t^2 \sigma^2,
\]

where the first inequality follows Assumption 12 and Lemma 20, the second inequality follows Jensen’s inequality, the third inequality follows Assumption 10. Let $\mu_t \leq \frac{1}{2BL}$, then we have

\[
E_t \left[\|w_{m}^{t,b} - w^t\|^2\right] \leq \left(1 - \frac{1}{2(B - 1)}\right) E_t \left[\|w_{m}^{t,b-1} - w^t\|^2\right] + 2 \mu_t^2 \|\nabla F_m (w^t)\|^2 + \mu_t^2 \sigma^2.
\]

By induction, we then have

\[
E_t \left[\|w_{m}^{t,b} - w^t\|^2\right] \leq \left(2 \mu_t^2 \|\nabla F_m (w^t)\|^2 + \mu_t^2 \sigma^2\right)^{b-1} \left(1 - \frac{1}{2(B - 1)}\right)^{\tau}
\]

Since

\[
\sum_{\tau=0}^{b-1} \left(1 - \frac{1}{2(B - 1)}\right)^{\tau} = 1 - \left(1 - \frac{1}{2(B - 1)}\right)^{b-1} \leq \left(1 - \frac{1}{2(B - 1)}\right) = 2(B - 1) \leq 2B,
\]

thus we have

\[
E_t \left[\|w_{m}^{t,b} - w^t\|^2\right] \leq 4B^2 \mu_t^2 \|\nabla F_m (w^t)\|^2 + 2 \mu_t^2 \sigma^2,
\]

which then implies that

\[
\frac{1}{M} \sum_{m=1}^{M} \sum_{b=0}^{B-1} E_t \left[\|w_{m}^{t,b} - w^t\|^2\right] \leq 4B^2 \mu_t^2 \frac{1}{M} \sum_{m=1}^{M} \|\nabla F_m (w^t)\|^2 + 2 \mu_t^2 \sigma^2
\]

56
where the last inequality follows the definition of $\zeta_0$. We thus have proved (50).

Besides, we have

\[
\tilde{\mu} L^2 \left( \frac{1}{2} + \frac{1}{4\alpha} \right) \mathbb{E}_t \left[ \frac{1}{M} \sum_{m=1}^{M} \sum_{b=0}^{B-1} \frac{1}{M} \sum_{m=1}^{M} \sum_{b=0}^{B-1} \left\| w_{m}^{t,b} - w^t \right\|^2 \right] \leq \left( 2 + \frac{1}{\alpha} \right) \tilde{\mu} \mu^2 B^2 L^2 \| \nabla F(w^t) \|^2 + \left( 1 + \frac{1}{2\alpha} \right) \tilde{\mu} \mu^2 B^2 L^2 \sigma^2.
\]

Combine the above result with (49), we have

\[
\mathbb{E}_t \left[ F(w^{t+1}) \right] \leq F(w^t) - \frac{\tilde{\mu} B}{4} \left( 1 - \left( 2 + \frac{1}{\alpha} \right) \mu^2 B^2 L^2 \right) \| \nabla F(w^t) \|^2 + \left( 2 + \frac{1}{\alpha} \right) \tilde{\mu} \mu^2 B^2 L^2 \left( B \zeta_0^2 + \frac{\sigma^2}{2} \right) + \frac{\tilde{\mu}^2 BL}{K} \left( \frac{\sigma^2}{2\alpha} + B \zeta_0^2 \right) + \frac{BL\tilde{\mu}^2\mu^2}{2} \mathbb{E}_t \left[ l_t(\hat{p}^t) - l_t(q^*) \right].
\]

Let $\mu_t \leq \frac{1}{4BL} \sqrt{\frac{1}{1+1/(2\alpha)}}$, we then have

\[
\mathbb{E}_t \left[ F(w^{t+1}) \right] \leq F(w^t) - \frac{\tilde{\mu} B}{8} \| \nabla F(w^t) \|^2 + \left( 2 + \frac{1}{\alpha} \right) \tilde{\mu} \mu^2 B^2 L^2 \left( B \zeta_0^2 + \frac{\sigma^2}{2} \right) + \frac{\tilde{\mu}^2 BL}{K} \left( \frac{\sigma^2}{2\alpha} + B \zeta_0^2 \right) + \frac{BL\tilde{\mu}^2\mu^2}{2} \mathbb{E}_t \left[ l_t(\hat{p}^t) - l_t(q^*) \right],
\]

which then implies that

\[
\left\| \nabla F(w^t) \right\|^2 \leq \frac{8}{\tilde{\mu} B} \left( F(w^t) - \mathbb{E}_t \left[ F(w^{t+1}) \right] \right) + 8 \left( 2 + \frac{1}{\alpha} \right) \mu^2 B^2 L^2 \left( \zeta_0^2 + \frac{\sigma^2}{2B} \right) + \frac{8\tilde{\mu} BL}{K} \left( \frac{\sigma^2}{2B\alpha} + \zeta_0^2 \right) + 4L\tilde{\mu} \mathbb{E}_t \left[ l_t(\hat{p}^t) - l_t(q^*) \right].
\]

Taking full expectation on both sides, summing over $t = 0$ to $t = T - 1$ and taking average, we then have

\[
\frac{1}{T} \sum_{t=0}^{T-1} \mathbb{E} \left[ \left\| \nabla F(w^t) \right\|^2 \right] \leq \frac{8}{\tilde{\mu} B} \left( F(w^0) - \mathbb{E} \left[ F(w^T) \right] \right) + 8 \left( 2 + \frac{1}{\alpha} \right) \mu^2 B^2 L^2 \left( \zeta_0^2 + \frac{\sigma^2}{2B} \right) + \frac{8\tilde{\mu} BL}{K} \left( \frac{\sigma^2}{2B\alpha} + \zeta_0^2 \right) + 4L\tilde{\mu} \times D-\text{Regret}_T(q^*) \leq \frac{8}{\tilde{\mu} B} \left( F(w^0) - F^* \right) + 8 \left( 2 + \frac{1}{\alpha} \right) \mu^2 B^2 L^2 \left( \zeta_0^2 + \frac{\sigma^2}{2B} \right).\]

57
\[ + \frac{8\hat{\mu}BL}{K} \left( \frac{\sigma^2}{2B\alpha} + \zeta_0^2 \right) + 4L\hat{\mu} \times \text{D-Regret}_T(q^*) \].

In summary, when \( \hat{\mu} \leq \frac{1}{4BL} \) and \( \mu_l \leq \frac{1}{4BL} \sqrt{\frac{1}{1 + 1/(2\alpha)}} \), we have

\[ E \left[ \| \nabla F(w^R) \|^2 \right] = \frac{1}{T} \sum_{t=0}^{T-1} E \left[ \| \nabla F(w^t) \|^2 \right] \]

\[ \leq \frac{8}{\hat{\mu}BT} (F(w^0) - F^*) + 8 \left( 2 + \frac{1}{\alpha} \right) \hat{\mu}^2 B^2 L^2 \left( \zeta_0^2 + \frac{\sigma^2}{2B} \right) \]

\[ + 4\hat{\mu}BL \left( \frac{2\zeta_1^2}{K} + \frac{\sigma^2}{KB\alpha} + \frac{\text{D-Regret}_T(q^*)}{BT} \right). \]

By letting \( \mu \geq 1, \hat{\mu} \leq \frac{1}{4BL} \sqrt{\frac{1}{1 + 1/(2\alpha)}} \) and recall that \( D^F = F(w^0) - F^* \), we then have

\[ E \left[ \| \nabla F(w^R) \|^2 \right] \leq \frac{8D^F}{\hat{\mu}BT} + 8 \left( 2 + \frac{1}{\alpha} \right) \hat{\mu}^2 B^2 L^2 \left( \zeta_0^2 + \frac{\sigma^2}{2B} \right) \]

\[ + 4\hat{\mu}BL \left( \frac{2\zeta_1^2}{K} + \frac{\sigma^2}{KB\alpha} + \frac{\text{D-Regret}_T(q^*)}{BT} \right). \]

When letting

\[ \frac{8D^F}{\hat{\mu}BT} = 8 \left( 2 + \frac{1}{\alpha} \right) \hat{\mu}^2 B^2 L^2 \left( \zeta_0^2 + \frac{\sigma^2}{2B} \right), \]

we have

\[ \hat{\mu} = \frac{(D^F)^{\frac{1}{2}}}{(2 + \frac{1}{\alpha})^{\frac{1}{2}} BL^{\frac{1}{2}} \left( \zeta_0^2 + \frac{\sigma^2}{2B} \right)^{\frac{1}{2}}} T^{\frac{1}{2}}, \]

which implies that

\[ \frac{8D^F}{\hat{\mu}BT} + 8 \left( 2 + \frac{1}{\alpha} \right) \hat{\mu}^2 B^2 L^2 \left( \zeta_0^2 + \frac{\sigma^2}{2B} \right) \leq \frac{16 \left( 2 + \frac{1}{\alpha} \right)^{\frac{1}{2}} (D^F)^{\frac{1}{2}} L^{\frac{1}{2}} \left( \zeta_0^2 + \frac{\sigma^2}{2B} \right)^{\frac{1}{2}}}{T^{\frac{1}{2}}} \]

\[ \leq \frac{16 \left( 2 + \frac{1}{\alpha} \right)^{\frac{1}{2}} (D^F)^{\frac{1}{2}} L^{\frac{1}{2}} \left( \zeta_0^2 + \frac{\sigma^2}{2B} \right)^{\frac{1}{2}}}{T^{\frac{1}{2}}}. \]

On the other hand, when letting

\[ \frac{8D^F}{\hat{\mu}BT} = 4\hat{\mu}BL \left( \frac{2\zeta_1^2}{K} + \frac{\sigma^2}{KB\alpha} + \frac{\text{D-Regret}_T(q^*)}{BT} \right), \]

we have

\[ \hat{\mu} = \frac{\sqrt{2D^F}}{B\sqrt{L} \sqrt{\frac{2\zeta_1^2}{K} + \frac{\sigma^2}{KB\alpha} + \frac{\text{D-Regret}_T(q^*)}{BT}}} \sqrt{T}. \]
which implies that

\[
\frac{8D^F}{\tilde{\mu}BT} + 4\tilde{\mu}BL\left(\frac{2c_1^2}{K} + \frac{\sigma^2}{KB\alpha} + \frac{\text{D-Regret}_T(q^*)}{BT}\right)
\]

\[
\leq \frac{8\sqrt{2D^F} \sqrt{L} \frac{2c_1^2}{K} + \frac{\sigma^2}{KB\alpha} + \frac{\text{D-Regret}_T(q^*)}{BT}}{\sqrt{T}}
\]

\[
\leq \frac{8\sqrt{2D^F} \sqrt{L} \left(\frac{\sqrt{2}\zeta_1}{\sqrt{K}} + \frac{\sigma}{\sqrt{KB\alpha}} + \sqrt{\frac{\text{D-Regret}_T(q^*)}{BT}}\right)}{\sqrt{T}}.
\]

Thus, when \(\mu \geq 1\) and

\[
\tilde{\mu} = \min \left\{ \frac{1}{4BL}\sqrt{\frac{1}{1 + 1/(2\alpha)}}, \frac{(D^F)^{\frac{1}{3}}}{(2 + \frac{1}{\alpha})^{\frac{1}{3}}BL^{\frac{2}{3}}(c_0^2 + \frac{\sigma^2}{2})^{\frac{1}{3}T^{\frac{4}{3}}}}, \sqrt{\frac{2D^F}{B\sqrt{L}(\frac{2c_1^2}{K} + \frac{\sigma^2}{KB\alpha} + \frac{\text{D-Regret}_T(q^*)}{BT})}} \right\},
\]

we then have

\[
\mathbb{E} \left[ \left\| \nabla F(w^R) \right\|^2 \right] \leq \frac{32D^F L}{T} \frac{1 + \frac{1}{2\alpha}}{T^{\frac{2}{3}}} + \frac{16 (2 + \frac{1}{\alpha})^{\frac{1}{3}} (D^F)^{\frac{2}{3}} L^{\frac{2}{3}} (c_0^2 + \frac{\sigma^2}{2B})^{\frac{1}{3}T^{\frac{4}{3}}}}{T^{\frac{2}{3}}} + \frac{8\sqrt{2D^F} \sqrt{L} \left(\frac{\sqrt{2}\zeta_1}{\sqrt{K}} + \frac{\sigma}{\sqrt{KB\alpha}} + \sqrt{\frac{\text{D-Regret}_T(q^*)}{BT}}\right)}{\sqrt{T}}
\]

\[
\leq \frac{D^F L}{T} \frac{1 + \frac{1}{2\alpha}}{T^{\frac{2}{3}}} + \frac{(2 + \frac{1}{\alpha})^{\frac{1}{3}} (D^F)^{\frac{2}{3}} L^{\frac{2}{3}} (c_0^2 + \frac{\sigma^2}{2B})^{\frac{1}{3}T^{\frac{4}{3}}}}{T^{\frac{2}{3}}} + \frac{\sqrt{D^F} \sqrt{L} \zeta_1}{\sqrt{TK}} + \frac{\sqrt{D^F} L \sigma}{\sqrt{TKB\alpha}} + \frac{\sqrt{D^F} L \zeta_1}{\sqrt{TK}} + \frac{\sqrt{D^F} L \sigma}{\sqrt{TKB\alpha}} + \frac{\sqrt{D^F} L \zeta_1}{\sqrt{TK}} + \frac{\sqrt{D^F} L \sigma}{\sqrt{TKB\alpha}} + \frac{\sqrt{D^F} L \zeta_1}{\sqrt{TK}} + \frac{\sqrt{D^F} L \sigma}{\sqrt{TKB\alpha}}
\]

\[
\leq \frac{D^F L}{T} \frac{1 + \frac{1}{2\alpha}}{T^{\frac{2}{3}}} + \frac{(2 + \frac{1}{\alpha})^{\frac{1}{3}} (D^F)^{\frac{2}{3}} L^{\frac{2}{3}} (c_0^2 + \frac{\sigma^2}{2B})^{\frac{1}{3}T^{\frac{4}{3}}}}{T^{\frac{2}{3}}} + \frac{\sqrt{D^F} \sqrt{L} \zeta_1}{\sqrt{TK}} + \frac{\sqrt{D^F} L \sigma}{\sqrt{TKB\alpha}} + \frac{\sqrt{D^F} L \zeta_1}{\sqrt{TK}} + \frac{\sqrt{D^F} L \sigma}{\sqrt{TKB\alpha}}
\]

\[
B. \text{ Useful Lemmas}
\]

**Lemma 18** Suppose that \(f\) is a differentiable convex function defined on \(\text{dom} f\), and \(X \subseteq \text{dom} f\) is a closed convex set. Then \(x\) is the minimizer of \(f\) on \(X\) if and only if

\[
\nabla f(x)^\top (y - x) \geq 0 \quad \text{for all} \ y \in X.
\]
Lemma 19 Let \( f : \mathcal{W} \to \mathbb{R} \) be defined on \( \mathcal{W} \subseteq \mathbb{R}^d \), where \( \mathcal{W} \) is a convex set. Suppose that \( f \) is continuously differentiable and first-order \( L \)-smooth, that is,
\[
\| \nabla f(x) - \nabla f(y) \| \leq L \| x - y \| \quad \text{for all } x, y \in \mathcal{W},
\]
then we have
\[
|f(y) - f(x) - \langle \nabla f(x), y - x \rangle| \leq \frac{L}{2} \| x - y \|^2 \quad \text{for all } x, y \in \mathcal{W}.
\]

Proof [Theorem 2.1.5 of Nesterov et al. (2018)] Note that
\[
|f(y) - f(x) - \langle \nabla f(x), y - x \rangle| = \int_0^1 \langle \nabla f(x + t(y - x)), y - x \rangle \, dt - \langle \nabla f(x), y - x \rangle \leq \int_0^1 \| \nabla f(x + t(y - x)) - \nabla f(x) \| \| y - x \| \, dt \leq \int_0^1 L \| y - x \|^2 \, dt = \frac{L}{2} \| y - x \|^2,
\]
which then implies the conclusion.

Lemma 20 (Relaxed Triangle Inequality) This is Lemma 3 of Karimireddy et al. (2020b). Let \( \{v_1, \ldots, v_\tau\} \) be \( \tau \) vectors in \( \mathbb{R}^d \). Then the following are true:
\[
\|v_i + v_j\|^2 \leq (1 + a)\|v_i\|^2 + \left(1 + \frac{1}{a}\right)\|v_j\|^2 \quad \text{for any } a > 0,
\]
\[
\left\| \sum_{i=1}^\tau v_i \right\|^2 \leq \tau \sum_{i=1}^\tau \|v_i\|^2.
\]

Proof See Lemma 3 of Karimireddy et al. (2020b).

Lemma 21 For \( q \in \mathcal{P}_{M-1} \) we have \( D_\Phi(q \| p^{\text{unif}}) \leq \log M \), where \( \Phi \) is the unnormalized negative entropy.
**Proof** Since \( \Phi(q) = \sum_{m=1}^{M} q_m (\log q_m - 1) \leq 0 \), \( \Phi(p_{\text{unif}}) = -\log M \), and

\[
\langle \nabla \Phi(p_{\text{unif}}), q - p_{\text{unif}} \rangle = \sum_{m=1}^{M} (q_m - \frac{1}{M}) \log \frac{1}{M} = 0,
\]

we have \( D_\Phi(q \| p) \leq \log M \).

**Lemma 22 (Hoeffding’s Inequality)** Let \( X \) be a random variable with \( a \leq X \leq b \) for \( a, b \in \mathbb{R} \). Then for all \( s \in \mathbb{R} \), we have

\[
\log \mathbb{E}[e^{sX}] \leq s \mathbb{E}[X] + \frac{s^2(b-a)^2}{8}.
\]

**Proof** See Section 2 of Wainwright (2019).

**Lemma 23 (Based on Exercise 26.12 of Lattimore and Szepesvári (2020))** Let \( \alpha \in [0, 1] \), \( A = \mathcal{P}_{M-1} \cap [\alpha/M, 1]^M \), \( D = [0, \infty)^M \), and \( \Phi = \Phi_e \) is the unnormalised entropy on \( \mathcal{D} \). For \( y \in [0, \infty)^M \), let \( x = \arg \min_{v \in A} D_\Phi(v \| y) \). Suppose \( y_1 \leq y_2 \leq \cdots \leq y_M \). Let \( m^\star \) be the smallest value such that

\[
y_{m^\star} \left( 1 - \frac{m^\star - 1}{M} \alpha \right) > \frac{\alpha}{M} \sum_{m=m^\star}^{M} y_m.
\]

Then

\[
x_m = \begin{cases} \frac{\alpha}{M} & \text{if } m < m^\star \\ \frac{(1 - \frac{m^\star - 1}{M} \alpha) y_m}{\sum_{m=m^\star}^{M} y_m} & \text{otherwise.} \end{cases}
\]

**Proof** Consider the following constrained optimization problem:

\[
\min_{u \in [0, \infty)^M} \sum_{m=1}^{M} u_m \log \frac{u_m}{y_m},
\]

s.t.

\[
\sum_{m=1}^{M} u_m = 1,
\]

\[
u_m \geq \frac{\alpha}{M}, \quad m \in [M].
\]

Since \( x \) is the solution to this problem, by the optimality condition, there exists \( \lambda, \nu_1, \ldots, \nu_M \in \mathbb{R} \) such that

\[
\log \frac{x_m}{y_m} + 1 - \lambda - \nu_m = 0, \quad m \in [M],
\]

\[
\sum_{m=1}^{M} x_m = 1,
\]

(51)

(52)
\[ x_m - \frac{\alpha}{M} \geq 0, \quad m \in [M], \tag{53} \]
\[ \nu_m \geq 0, \quad m \in [M], \tag{54} \]
\[ \nu_m \left( x_m - \frac{\alpha}{M} \right) = 0, \quad m \in [M]. \tag{55} \]

By (51), we have \( x_m = y_m \exp(-1 + \lambda + \nu_m) \). By (54) and (55), when \( x_m = \alpha/M \), we have \( x_m = y_m \exp(-1 + \lambda) \). Assume that \( x_1 = \cdots = x_{m^* - 1} = \alpha/M < x_{m^*} \leq \cdots \leq x_M \). Then

\[
1 = \sum_{m=1}^{M} x_m = (m^* - 1) \frac{\alpha}{M} + \exp(-1 + \lambda) \cdot \sum_{m=m^*}^{M} y_m,
\]

which implies that

\[
\exp(-1 + \lambda) = \frac{1 - (m^* - 1) \frac{\alpha}{M}}{\sum_{m=m^*}^{M} y_m}.
\tag{56}
\]

Thus, we have

\[
x_{m^*} = y_{m^*} \exp(-1 + \lambda) = y_{m^*} \frac{1 - (m^* - 1) \frac{\alpha}{M}}{\sum_{m=m^*}^{M} y_m} > \frac{\alpha}{M},
\]

which implies that

\[
y_{m^*} \left( 1 - \frac{m^* - 1}{M} \alpha \right) > \frac{\alpha}{M} \sum_{m=m^*}^{M} y_m.
\tag{57}
\]

To complete the proof, we then only need to show that

\[
y_{m'} \left( 1 - \frac{m' - 1}{M} \alpha \right) \leq \frac{\alpha}{M} \sum_{m=m'}^{M} y_m
\tag{58}
\]

for all \( 1 \leq m' \leq m^*-1 \). The result then follows from (57) and (58). To prove (58), recall that for any \( 1 \leq m' \leq m^*-1 \), we have \( \alpha/M = y_{m'} \exp(-1 + \lambda + \nu_{m'}) \), and because \( y_1 \leq \cdots \leq y_M \), we have \( \nu_1 \geq \cdots \geq \nu_{m^*-1} \). This way, we have

\[
(m^* - m') \frac{\alpha}{M} = \sum_{m=m'}^{m^*} y_m \exp(-1 + \lambda + \nu_m) \leq \exp(-1 + \lambda + \nu_{m'}) \sum_{m=m'}^{m^* - 1} y_m.
\tag{59}
\]

On the other hand, by (56), we have

\[
1 - (m^* - 1) \frac{\alpha}{M} = \exp(-1 + \lambda) \sum_{m=m^*}^{M} y_m \leq \exp(-1 + \lambda + \nu_{m'}) \sum_{m=m^*}^{M} y_m.
\tag{60}
\]

Combining (59) and (60), we have

\[
\frac{1 - (m' - 1) \frac{\alpha}{M}}{\sum_{m=m'}^{M} y_m} = \frac{1 - (m^* - 1) \frac{\alpha}{M} + (m^* - m') \frac{\alpha}{M}}{\sum_{m=m'}^{M} y_m}
\]

62
\[
\leq \frac{\exp \left( -1 + \lambda + \nu_m' \right) \left( \sum_{m=m'} y_m + \sum_{m=m'}^M y_m \right)}{\sum_{m=m'}^M y_m} \\
= \exp \left( -1 + \lambda + \nu_m' \right) \\
= \frac{\alpha}{y_{m_1}} 
\]
which then implies (58).  \( \blacksquare \)
