**ABSTRACT**

Precise design of graphitic carbon nitride (gC$_3$N$_4$) nanostructures is of grand importance in different catalytic applications. This article emphasizes additional data on the fabrication of metal-free gC$_3$N$_4$ nanofibres (gC$_3$N$_4$NFs) and its associated structural and composition analysis compared with Au/Pd co-doped gC$_3$N$_4$ nanofibres (Au/Pd/gC$_3$N$_4$NFs). The data is including the typical fabrication process of metal-free gC$_3$N$_4$ nanofibres and its SEM, TEM, and element mapping analysis beside Raman, and FTIR spectra relative to Au/Pd/gC$_3$N$_4$NFs. We also investigated the catalytic CO oxidation durability testes on Au/Pd/gC$_3$N$_4$NFs compared to Pd/gC$_3$N$_4$NFs and Au/gC$_3$N$_4$NFs. The presented data are associated with the research article entitled “Rational synthesis of one-dimensional carbon nitride-based nanofibers atomically doped with Au/Pd for efficient carbon monoxide oxidation.” [1].

1. Data

The presented herein data provides deep insights on the rational synthesis of metal-free gC3N4NFs and its correlated analysis relative to Au/Pd/gC3N4NFs. This is in addition to the CO oxidation durability of Au/Pd/gC3N4NFs and its compositional analysis after CO oxidation reaction. Particularly, the data involves the SEM, TEM, and elemental mapping images of gC3N4NFs (Fig. 1), while the FTIR and Raman spectra of gC3N4NFs compared to Au/Pd/gC3N4 are represented in Fig. 2 and Fig. 3, respectively. Meanwhile, the CO oxidation stability testes carried out on Au/Pd/gC3N4NFs, Pd/gC3N4NFs, and Au/gC3N4NFs beside their loss in the complete conversion temperature (T100) are shown in (Fig. 4). This is alongside the Energy Dispersive X-ray Analysis (EDX) analysis of Au/Pd/gC3N4NFs after the CO oxidation durability testes (Fig. 5) and the schematic reveals the synthetic mechanism process of Au/Pd/gC3N4NFs in (Fig. 6).

2. Experimental design, materials, and methods

2.1. Synthesis of metal-free gC3N4NFs

Fig. 1 shows the SEM and TEM images of metal-free gC3N4NFs typically synthesized by the slow dispersion of melamine (1 g) in an aqueous solution of isopropanol (30 mL, 99%) under stirring at 40 °C. Then, an aqueous solution of nitric acid (HNO3, 60 mL, 0.3 M) was added to the previous solution under stirring at 40 °C. The as-formed white precipitate was filtered and washed with isopropanol solution before being dried at 100 °C for 12 h. Finally, the obtained powder was subsequently annealed under nitrogen at 550 °C for 2 h (5 °C min⁻¹).
The fabrication of Au/Pd/gC3N4NFs was done according to the same procedure of metal-free gC3N4NFs but in presence of Au and Pd precursors before the addition of HNO₃ (see Ref. [1] for more information).

The SEM image clearly shows the formation of uniform one-dimensional fiber-like morphology in high yield (nearly 100%) without resolving any other undesired shapes such as spherical and sheets (Fig. 1a). The average length of thus formed nanofibers obtained from the TEM is about 10 μm. The TEM image further confirmed the formation of a nanofiber structure with smooth surfaces and had an average width of nearly 80 ± 2 nm (Fig. 1b). The element mapping analysis indicated the presence of both C and N with an atomic ratio of 41 and 59, respectively (Fig. 1c and d).

2.2. Chemical structure and composition analysis

The chemical bonds and the functional groups of both Au/Pd/gC3N4NFs and gC3N4NFs were evaluated using the Fourier transform infrared (FTIR) analysis. Both Au/Pd/gC3N4NFs and gC3N4NFs revealed the peaks attributed to the stretching vibration of triazine at 810 cm⁻¹ and several peaks for C–N heterocycles from 1000 to 1750 cm⁻¹ (Fig. 2) [2]. The weak bands observed between 2900 and 3300 cm⁻¹ are assigned to the N–H vibrations at the edges of gC3N4-based material. The anchoring of

![Fig. 1.](image-url)
Au and Pd over N-atoms inside Au/Pd/gC3N4NFs slightly broadens and decreases in the intensity of N–H and C–N bands of Au/Pd/gC3N4NFs [1–4].

Fig. 3a shows the Raman spectra of typically formed Au/Pd/gC3N4NFs and gC3N4NFs. Both materials revealed a sharp peak at 1555 cm\(^{-1}\) of graphitic (G) band, which indicates the high degree of graphitization of the as-obtained materials [4,5]. The G band of Au/Pd/gC3N4NFs was slightly positively shifted relative to that of gC3N4NFs, implying its higher strained effect. Additionally, both materials

displayed a small spectrum at 2690 cm\(^{-1}\) of \((\text{G}^`\text{peak})\), resulting from the disordered surface. Fig. 3b shows the typical spectrum of melamine starting from 500 until 3000 cm\(^{-1}\), which are dissimilar to those recorded for Au/Pd/gC\(_3\)N\(_4\)NFs and gC\(_3\)N\(_4\)NFs \([1–3]\). Table 1 summarizes the identification and position for Raman spectra of Au/Pd/gC\(_3\)N\(_4\)NFs and gC\(_3\)N\(_4\)NFs.

### 2.3. CO oxidation stability tests

The CO oxidation is of particular interest in wide varieties of industrial, biological, and environmental remediation applications \([2,6–8]\). Thus, it is essential to develop efficient and durable catalysts for CO oxidation reaction to convert highly toxic CO gas into less toxic gasses or other fuels \([1–4,8–11]\). After determination, the complete CO conversion temperature (T\(_{100}\)) on the as-synthesized Au/Pd/gC\(_3\)N\(_4\)NFs, Pd/gC\(_3\)N\(_4\)NFs, and Au/gC\(_3\)N\(_4\)NFs, the long-term durability tests were investigated at their T\(_{100}\) for 48 h. In particular, the catalysts were exposed to the gas mixture consisting of CO (4%), O\(_2\) (20%), and Ar (76%) with a total flow of 50 mL min\(^{-1}\) and the temperature was increased steadily (5 °C min\(^{-1}\)) until the T\(_{100}\) of each catalyst. Then, the percentage of CO conversion was monitored through an online multichannel infrared gas analyzer (IR200, Yokogawa, Japan). Following the durability tests, the CO conversion efficiencies were measured again through the pretreatment at 250 °C under an O\(_2\) flow of 50 mL min\(^{-1}\), and H\(_2\) (30 mL min\(^{-1}\)) for 1 h. Then, each catalyst was exposed to a gas mixture of CO (4%), O\(_2\) (20%), and Ar (76%) with a total flow of 50 mL min\(^{-1}\), while heating from the room temperature till the complete CO conversion occurred.

Fig. 4 shows the CO oxidation durability of Au/Pd/gC\(_3\)N\(_4\)NFs compared to Pd/gC\(_3\)N\(_4\)NFs, and Au/gC\(_3\)N\(_4\)NFs. In particular, after the accelerated durability tests, Au/Pd/gC\(_3\)N\(_4\)NFs reserved its initial CO oxidation activity without any noticed loss (Fig. 4a); meanwhile, Pd/gC\(_3\)N\(_4\)NFs loss is around 7% (Fig. 4b) and Au/gC\(_3\)N\(_4\)NFs lose about 11% (Fig. 4c). However, from the light-off curves for the CO conversion durability expressed as a function of time, all materials did not show any noticed change in the CO oxidation kinetics. To this end, the estimated T\(_{100}\) after the stability cycles on Au/Pd/gC\(_3\)N\(_4\)NFs, Pd/gC\(_3\)N\(_4\)NFs, and Au/Pd/gC\(_3\)N\(_4\)NFs were about 146 °C, 203 °C, and 246.4 °C, respectively (Fig. 4d).

### 2.4. Compositional stability

After the CO oxidation durability tests, the elemental composition of Au/Pd/gC\(_3\)N\(_4\)NFs was carried out using the EDX analysis to examine any changes in the composition. Fig. 5 shows the EDX analysis of Au/Pd/gC\(_3\)N\(_4\)NFs, which revealed the presence of C, N, Au, and Pd without any changes or undesired phases. The detailed atomic ratios of C/N/Au/Pd are about with 39/60/0.51/0.44, respectively.

Chemically speaking, and looking deeply to the formation mechanism, Au/Pd/gC\(_3\)N\(_4\)NFs combine between the unique physicochemical properties of gC\(_3\)N\(_4\) and catalytic merits of Au/Pd atomic dopants \([1–4,12–15]\). Particularly, the strong binding affinity between N-atoms of melamine and metal atoms Au/Pd led to their chemical bonding in the form of -N-Au and -N-Pd during the polymerization step resulting in a coherent distribution through the skeletal structure of gC\(_3\)N\(_4\)NFs (Fig. 6) \([1–4]\). These chemical legends not only allow the homogenous distribution of Au/Pd inside the nanofibers but also stabilize them against the detachment and agglomeration, during the CO oxidation reaction.
