Abstract
We consider the following elliptic system
\[ \Delta u = \nabla H(u) \text{ in } \mathbb{R}^N, \]
where \( u : \mathbb{R}^N \to \mathbb{R}^m \) and \( H \in C^2(\mathbb{R}^m) \), and prove, under various conditions on the nonlinearity \( H \) that, at least in low dimensions, a solution \( u = (u_i)_{i=1}^m \) is necessarily one-dimensional whenever each one of its components \( u_i \) is monotone in one direction. Just like in the proofs of the classical De Giorgi’s conjecture in dimension 2 (Ghoussoub-Gui) and in dimension 3 (Ambrosio-Cabrè), the key step is a Liouville theorem for linear systems. We also give an extension of a geometric Poincaré inequality to systems and use it to establish De Giorgi type results for stable solutions as well as additional rigidity properties stating that the gradients of the various components of the solutions must be parallel. We introduce and exploit the concept of an orientable system, which seems to be key for dealing with systems of three or more equations. For such systems, the notion of a stable solution in a variational sense coincide with the pointwise (or spectral) concept of stability.

2010 Mathematics Subject Classification: 35J47, 35B08, 35B35, 35B40, 35B53.
Key words: Liouville theorems, energy estimates, elliptic systems, rigidity results, stable solutions.

1 Introduction
In 1978, Ennio De Giorgi proposed the following conjecture.

Conjecture 1. Suppose that \( u \) is an entire solution of the Allen-Cahn equation
\[ \Delta u + u - u^3 = 0 \text{ on } \mathbb{R}^N, \] (1)
satisfying \( |u(x)| \leq 1, \frac{\partial u}{\partial x_N}(x) > 0 \) for \( x = (x', x_N) \in \mathbb{R}^N \). Then, at least in dimensions \( N \leq 8 \) the level sets of \( u \) must be hyperplanes, i.e. there exists \( g \in C^2(\mathbb{R}) \) such that \( u(x) = g(ax' - x_N) \), for some fixed \( a \in \mathbb{R}^{N-1} \).

The first positive result on the De Giorgi conjecture was established in 1997 by Ghoussoub and Gui [11] for dimension \( N = 2 \). Their proof used the following linear Liouville type theorem for elliptic equations in divergence form, which (only) holds in dimensions 1 and 2 ([3, 11]). If \( \phi > 0 \), then any solution \( \sigma \) of
\[ \text{div}(\phi^2 \nabla \sigma) = 0, \] (2)

*Research partially supported by a University Graduate Fellowship at the University of British Columbia, under the supervision of the second-named author.
†Partially supported by a grant from the Natural Sciences and Engineering Research Council of Canada.
such that \( \phi \sigma \) is bounded, is necessarily constant. This result is then applied to the ratio \( \sigma := \frac{\partial u_i}{\partial x_j} \) to conclude in dimension 2. Ambrosio and Cabré [4] extended the result to dimension \( N = 3 \) by noting that for the linear Liouville theorem to hold, it suffices that

\[
\int_{B_R} \phi^2 \sigma^2 \leq CR^2,
\]

and by proving that any solution \( u \) satisfying \( \partial_N u > 0 \) satisfies the energy estimate

\[
\int_{B_R} \phi^2 \sigma^2 \leq CR^{N-1}.
\]

The conjecture remains open in dimensions \( 4 \leq N \leq 8 \). However, Ghoussoub and Gui also showed in [12] that it is true for \( N = 4 \) or \( N = 5 \) for solutions that satisfy certain antisymmetry conditions, and Savin [16] established its validity for \( 4 \leq N \leq 8 \) under the following additional natural hypothesis on the solution,

\[
\lim_{x_N \to \pm \infty} u(x', x_N) \to \pm 1.
\]

Unlike the above proofs in dimensions \( N \leq 5 \), the proof of Savin is nonvariational and does not use a Liouville type theorem. Our proofs below for analogous results corresponding to systems are more in the spirit of Ghoussoub-Gui and Ambrosio-Cabré, which mostly rely on notions of stability and on an interesting linear Liouville theorem that is suitable for non-linear elliptic systems of the following type:

\[
\Delta u = \nabla H(u) \quad \text{in} \quad \mathbb{R}^N,
\]

where \( u : \mathbb{R}^N \to \mathbb{R}^m, H \in C^2(\mathbb{R}^m) \) and \( \nabla H(u) = (H_{u_i}(u_1, u_2, \ldots u_m)) \). The notation \( H_{u_i} \) is for the partial derivative \( \frac{\partial H}{\partial u_i} \).

**Definition 1.** We shall say that the system \([6]\) (or the non-linearity \( H \)) is orientable, if there exist nonzero functions \( \theta_k \in C^1(\mathbb{R}^N), k = 1, \cdots , m \), which do not change sign, such that for all \( i, j \) with \( 1 \leq i < j \leq m \), we have

\[
H_{u_iu_j} \theta_i(x) \theta_j(x) \leq 0 \quad \text{for all} \quad x \in \mathbb{R}^N.
\]

Note that the above condition on the system means that none of the mixed derivative \( H_{u_iu_j} \) changes sign. It is clear that a system consisting of two equations (i.e., \( m = 2 \)) is always orientable as long as \( H_{u_1u_2} \) does not change sign. On the other hand, if \( m = 3 \), then the system \([6]\) cannot be orientable if, for example, all three mixed derivatives \( H_{u_iu_j} \) with \( i < j \) are positive. This concept of "orientable system" seems to be the right framework for dealing with systems of three or more equations. We shall see for example, that for such systems, the notions of variational stability and pointwise stability coincide.

We shall consider solutions of \([6]\) whose components \( (u_1, u_2, \ldots u_m) \) are strictly monotone in the last variable \( x_N \). However, and in contrast to the case of a single equation, the various components need not be all increasing (or decreasing). This leads us to the following definition of monotonicity.

**Definition 2.** Say that a solution \( u = (u_k)_{k=1}^m \) of \([6]\) is \( H \)-monotone if the following hold:

1. For every \( i \in \{1, \ldots , m\} \), \( u_i \) is strictly monotone in the \( x_N \)-variable (i.e., \( \partial_N u_i \neq 0 \)).
2. For \( i < j \), we have

\[
H_{u_iu_j} \partial_N u_i(x) \partial_N u_j(x) \leq 0 \quad \text{for all} \quad x \in \mathbb{R}^N.
\]

We shall then write \( I \cup J = \{1, \ldots , m\} \), where

\[
\partial_N u_i > 0 > \partial_N u_j \quad \text{for} \quad i \in I \quad \text{and} \quad j \in J.
\]

It is clear that the mere existence of an \( H \)-monotone solution for \([6]\) implies that the system is orientable, as it suffices to use \( \eta_i = \partial_N u_i \). We now recall two notions of stability that will be considered in the sequel.

**Definition 3.** A solution \( u \) of the system \([6]\) on a domain \( \Omega \) is said to be...
(i) **stable**, if the second variation of the corresponding energy functional is nonnegative, i.e., if
\[
\sum_{i} \int_{\Omega} |\nabla \zeta_i|^2 + \sum_{i,j} \int_{\Omega} H_{u_{i,j}} \zeta_i \zeta_j \geq 0,
\]  
(10) for every \( \zeta_k \in C^1_\text{c}(\Omega) \), \( k = 1, \ldots, m \).

(ii) **pointwise stable**, if there exist \( (\phi_i)_{i=1}^m \) in \( C^1(\Omega) \) that do not change sign and \( \lambda \geq 0 \) such that
\[
\Delta \phi_i = \sum_j H_{u_{i,j}} \phi_j - \lambda \phi_i \quad \text{in } \Omega \quad \text{for all } \ i = 1, \ldots, m,
\]  
(11) and \( H_{u_{i,j}} \phi_j \phi_i \leq 0 \) for \( 1 \leq i < j \leq m \).

Note that a system that possesses a pointwise stable solution is necessarily orientable. On the other hand, we shall prove in Section 2 that for solutions of orientable systems, the two notions of stability are equivalent.

The following Liouville theorem plays a key role in this paper. Note that for the case \( A \) linear Liouville theorem for systems and first applications

Assume that the level sets of each component \( u_i \), if there exist \( (\phi_i)_{i=1}^m \) that do not change sign and \( \lambda \geq 0 \) such that
\[
\Delta \phi_i = \sum_j H_{u_{i,j}} \phi_j - \lambda \phi_i \quad \text{in } \Omega \quad \text{for all } \ i = 1, \ldots, m,
\]  
and later by Ambrosio and Cabré [4] to prove the De Giorgi conjecture in dimensions two and three. Also, Ghoussoub and Gui in [12] used a slightly stronger version to show that the De Giorgi’s conjecture is true in dimensions four and five for a special class of solutions that satisfy an antisymmetry condition.

**Conjecture 2.** Suppose \( u = (u_i)_{i=1}^m \) is an \( H \)-monotone bounded entire solutions of the system (10), then at least in dimensions \( N \leq 8 \), the level sets of each component \( u_i \) must be a hyperplane.

We are extremely grateful to an anonymous referee for several important comments, including the suggestion that our methods could also lead to a solution of the conjecture in dimension 3, without the additional assumptions that we had used in the first version of this paper.

## 2 A linear Liouville theorem for systems and first applications

The following Liouville theorem plays a key role in this paper. Note that for the case \( m = 1 \), this type of Liouville theorem was noted by Berestycki, Caffarelli and Nirenberg in [6] and used by Ghoussoub-Gui [11] and later by Ambrosio and Cabré [4] to prove the De Giorgi conjecture in dimensions two and three. Also, Ghoussoub and Gui in [12] used a slightly stronger version to show that the De Giorgi’s conjecture is true in dimensions four and five for a special class of solutions that satisfy an antisymmetry condition.

**Proposition 1.** Assume that \( \phi_i \in L^\infty_{\text{loc}}(\mathbb{R}^N) \) are such that \( \phi_i^- > 0 \) a.e., and \( \sigma_i \in H^1_{\text{loc}}(\mathbb{R}^N) \) satisfy
\[
\sum_{i=1}^m \int_{B_{2R} \setminus B_R} \phi_i^2 \sigma_i^2 \leq CR^2.
\]  
(12) If \( (\sigma_i)_{i=1}^m \) are solutions of
\[
\text{div}(\phi_i^2 \nabla \sigma_i) + \sum_{j=1}^m h_{i,j}(x) f(\sigma_i - \sigma_j) + k_i(x) g(\sigma_i) = 0 \quad \text{in } \mathbb{R}^N \quad \text{for } i = 1, \ldots, m,
\]  
(13) where \( 0 \geq h_{i,j}, k_i \in L^1_{\text{loc}}(\mathbb{R}^N) \), \( h_{i,j} = h_{j,i} \) and \( f, g \in L^1_{\text{loc}}(\mathbb{R}) \) are odd functions such that \( f(t), g(t) \geq 0 \) for \( t \in \mathbb{R}^+ \). Then, for all \( i = 1, \ldots, m \), the functions \( \sigma_i \) are constant.

**Proof:** Multiply both sides of (13) by \( \sigma_i \zeta_R \) where \( \zeta_R \in C^1_\text{c}(\mathbb{R}^N) \) with \( 0 \leq \zeta_R \leq 1 \) being the following test function:
\[
\zeta_R(x) = \begin{cases} \ 1, & \text{if } |x| < R, \\ \ 0, & \text{if } |x| > 2R, \end{cases}
\]  
where \( ||\nabla \zeta_R||_\infty \leq R^{-1} \). By integrating by parts, we get
\[
\int_{B_{2R}} \phi_i^2 |\nabla \sigma_i|^2 \zeta_R^2 + 2 \int_{B_{2R}} \phi_i^2 \nabla \sigma_i \cdot \nabla \zeta_R \zeta_R \sigma_i - \int_{B_{2R}} \sum_j h_{i,j}(x) f(\sigma_i - \sigma_j) \sigma_i \zeta_R^2 - \int_{B_{2R}} k_i(x) g(\sigma_i) \sigma_i \zeta_R^2 = 0.
\]  
Summing the above identity over \( i \), we get
\[
\sum_{i=1}^m \int_{B_{2R}} \phi_i^2 |\nabla \sigma_i|^2 \zeta_R^2 = -2 \sum_{i,j=1}^m \int_{B_{2R} \setminus B_R} \phi_i^2 \nabla \sigma_i \cdot \nabla \zeta_R \zeta_R \sigma_i + \int_{B_{2R}} I(x) \zeta_R^2 + \int_{B_{2R}} J(x) \zeta_R^2,
\]  
3
An integration by parts yields,

\[ I(x) := \sum_{i,j} h_{ij}(x)\sigma_i f(\sigma_i - \sigma_j) \quad \text{and} \quad J(x) := \sum_i h_i(x)g(\sigma_i)\sigma_i. \]

Note that

\[ I(x) = \sum_{i,j} h_{ij}(x)\sigma_i f(\sigma_i - \sigma_j) = \sum_{i<j} h_{ij}\sigma_i f(\sigma_i - \sigma_j) + \sum_{i>j} h_{ij}\sigma_i f(\sigma_i - \sigma_j) = \sum_{i<j} h_{ij}\sigma_i f(\sigma_i - \sigma_j) = \sum_{i<j} h_{ij}(\sigma_i - \sigma_j)f(\sigma_i - \sigma_j) \]

since \( h_{ij} = h_{ji} \)

Since \( h_{i,j}(x) \leq 0 \) and \( (\sigma_i - \sigma_j) f(\sigma_i - \sigma_j) \geq 0 \) for all \( i, j \), we have \( I(x) \leq 0 \). Similarly, \( J(x) \leq 0 \). Therefore, for \( 0 < \epsilon < 1 \), we get Young’s inequality that

\[
\sum_{i=1}^{m} \int_{B_{2R}} \phi_i^2 |\nabla \sigma_i|^2 \zeta_R^2 \leq 2 \sum_{i=1}^{m} \int_{B_{2R} \setminus B_R} \phi_i^2 |\nabla \sigma_i||\nabla \zeta_R| \zeta_R \sigma_i \\
\leq \epsilon \sum_{i=1}^{m} \int_{B_{2R} \setminus B_R} \phi_i^2 |\nabla \sigma_i|^2 \zeta_R^2 + C_\epsilon \sum_{i=1}^{m} \int_{B_{2R} \setminus B_R} (\sigma_i \phi_i)^2 |\nabla \zeta_R|^2. \quad (14)
\]

By assumption \((12)\) we see that

\[
\sum_{i=1}^{m} \int_{\mathbb{R}^N} \phi_i^2 |\nabla \sigma_i|^2 \zeta_R^2 < \infty \quad \text{and} \quad \sum_{i=1}^{m} \int_{\mathbb{R}^N} (\sigma_i \phi_i)^2 |\nabla \zeta_R|^2 < \infty.
\]

Estimate \((14)\) then yields

\[
\sum_{i=1}^{m} \int_{\mathbb{R}^N} \phi_i^2 |\nabla \sigma_i|^2 \zeta_R^2 = 0,
\]

which means that \( \sigma_i \) for all \( i = 1, \ldots, m \) must be constant.

Our first application is the following extension of a recent result by Berestycki, Lin, Wei and Zhao \([7]\) who considered a system of \( m = 2 \) equations and the nonlinearity \( H(t, s) = \frac{1}{2} t^2 s^2 \), which also appear as a limiting elliptic system arising in phase separation for multiple states Bose-Einstein condensates.

**Theorem 1.** Suppose the nonlinearity \( H \) satisfies the condition:

\[
u_i H_{u_i} \geq 0 \quad \text{for all} \quad 1 \leq i \leq m. \quad (15)
\]

Then, any pointwise stable solution \( u \) of the system \((6)\), which satisfies

\[
\sum_i \int_{B_{2R} \setminus B_R} u_i^2 \leq CR^4, \quad (16)
\]

is necessarily one-dimensional.

**Proof:** Note that we do not assume here that \( u \) is bounded solution. Multiply both sides of \((6)\) with \( u_i \zeta^2 \) to get

\[
u_i \Delta u_i \zeta^2 = u_i H_{u_i} \zeta^2 \geq 0 \quad \text{in} \quad \mathbb{R}^N. \quad (17)
\]

An integration by parts yields,

\[
\int_{B_R} |\nabla u_i|^2 \zeta^2 \leq 2 \int_{B_R} |\nabla u_i||\nabla \zeta| u_i \zeta. \quad (18)
\]
Now, use the same test function as in the proof of Proposition 1 to obtain
\[
\sum_i \int_{B_R} |\nabla u_i|^2 \leq C R^{-2} \sum_i \int_{B_{2R}\setminus B_R} u_i^2 \leq C R^2. \tag{19}
\]
Since \( u \) is a pointwise stable solution of (6), there exist eigenfunctions \((\phi_i)_i\) such that
\[
\Delta \phi_i = \sum_j H_{u,uj} \phi_j - \lambda \phi_i \text{ in } \mathbb{R}^N, \tag{20}
\]
where \( \phi_i \) does not change sign, \( H_{u,uj} \phi_i(x) \phi_j(x) \leq 0 \) and \( \lambda \geq 0 \). For any fixed \( \eta = (\eta',0) \in \mathbb{R}^{N-1} \times \{0\} \), define \( \psi_i := \nabla u_i \cdot \eta \) and observe that \( \psi_i \) satisfies the following equation
\[
\Delta \psi_i = \sum_j H_{u,uj} \psi_j \text{ in } \mathbb{R}^N. \tag{21}
\]
It is straightforward to see that \( \sigma_i := \frac{\psi_i}{\psi_i^\infty} \) is a solution of system (13) with \( h_{i,j}(x) = H_{u,uj} \phi_i(x) \phi_j(x) \), \( k_i(x) = -\lambda \phi_i^2 \) and \( f, g \) equal the identity. Apply now Proposition 1 to deduce that \( \sigma_i \) is constant for every \( i = 1, \ldots, m \), which clearly yields our claim. \( \square \)

**Remark 1.** Note that in the case where \( m = 2 \) and \( H(t,s) = \frac{1}{2} t^2 s^2 \), the above theorem yields that any positive solution \((u,v)\) of the corresponding system (6), which satisfies the growth assumption \( u(x), v(x) = O(|x|^\alpha) \) and such that \( \partial_N u > 0, \partial_N v < 0 \), is necessarily one-dimensional provided \( N \leq 4 - 2k \). Note that Noris et al. [12] have recently shown that a solution such that \( u(x), v(x) \leq C(1 + |x|^\alpha) \) is necessarily constant.

We can also deduce the following Liouville theorem for bounded solutions of (6) with general non-positive nonlinearities. The approach to this Liouville theorem seems to be new, even for single equations. It is worth comparing to the general results of Nedev [14] and Cabrè [8] regarding the regularity of stable solutions of semilinear equations with general nonlinearities up to dimension four.

**Theorem 2.** Suppose \( H \) is a nonlinearity verifying
\[
H_{u,i} \leq 0 \quad \text{for all } i = 1, \ldots, m. \tag{22}
\]
If the dimension \( N \leq 4 \), then any bounded pointwise stable solution of the system (6) is necessarily constant.

**Proof:** Multiply both sides of system (6) with \((u_i - \|u_i\|_\infty)\zeta^2\). Since \( H_{u,i}(u_i - \|u_i\|_\infty) \geq 0 \) we have
\[
\Delta u_i(u_i - \|u_i\|_\infty) \zeta^2 \geq 0 \text{ in } \mathbb{R}^N. \tag{23}
\]
After an integration by parts, we end up with
\[
\int_{B_R} |\nabla u_i|^2 \zeta^2 \leq 2 \int_{B_R} |\nabla u_i| |\nabla \zeta|(\|u_i\|_\infty - u_i) \zeta \quad \text{for all } 1 \leq i \leq m. \tag{24}
\]
Using Young’s inequality and adding we get
\[
\sum_i \int_{B_R} |\nabla u_i|^2 \leq R^{N-2}. \tag{25}
\]
As in the preceding theorem, one can apply Proposition 1 to quotients of partial derivatives to obtain that each \( u_i \) is one dimensional solutions as long as \( N \leq 4 \). Note now that \( u_i \) is a bounded solution for (23) in dimension one, and the corresponding decay estimate (25) now implies that \( u_i \) must be constant for all \( 1 \leq i \leq m \). \( \square \)

We now show that stability and pointwise stability are equivalent for solutions of orientable elliptic systems.

**Lemma 1.** A \( C^2 \)-function is a pointwise stable solution of the system (6) if and only if it is a stable solution and the system is orientable.
\textbf{Proof:} Assume first that \( u \) is a pointwise stable solution for \((6)\). It is clear that the system is then obviously orientable. In order to show that \( u \) is a stable solution, we consider test functions \( \zeta \in C^1_c(\mathbb{R}^N) \) and multiply both sides of \((11)\) with \( \frac{\partial \zeta}{\partial t} \) to obtain
\[
- \int_{\mathbb{R}^N} |\nabla \phi_i|^2 \frac{\partial^2}{\partial t^2} \phi_i + 2 \int_{\mathbb{R}^N} \nabla \phi_i \cdot \nabla \zeta \cdot \frac{\partial \zeta}{\partial t} + \sum_j \int_{\mathbb{R}^N} H_{u_{i,j}} \frac{\partial \zeta}{\partial t} \phi_i - \lambda \zeta^2 = 0.
\]
By applying Young’s inequality for the first two terms and taking sums, we get
\[
\sum_i \int_{\mathbb{R}^N} |\nabla \zeta|^2 + \sum_{i,j} \int_{\mathbb{R}^N} H_{u_{i,j}} \frac{\partial \zeta_i}{\partial t} \zeta_i^2 \geq \lambda \sum_i \int_{\mathbb{R}^N} \zeta_i^2 \geq 0.
\]
Note now that
\[
\sum_{i,j} H_{u_{i,j}} \frac{\partial \zeta_i}{\partial t} \zeta_i^2 = \sum_i H_{u_{i,j}} \zeta_i^2 + \sum_{i\neq j} H_{u_{i,j}} \zeta_i^2 \\
= \sum_i H_{u_{i,j}} \zeta_i^2 + \sum_{i<j} H_{u_{i,j}} \frac{\partial \zeta_i}{\partial t} \zeta_i^2 + \sum_{i>j} H_{u_{i,j}} \frac{\partial \zeta_i}{\partial t} \zeta_i^2 \\
= \sum_i H_{u_{i,j}} \zeta_i^2 + \sum_{i<j} H_{u_{i,j}} (\phi_i \phi_j)^{-1} (\zeta_i^2 + \zeta_j^2) \\
\leq \sum_i H_{u_{i,j}} \zeta_i^2 + 2 \sum_{i<j} H_{u_{i,j}} \zeta_i \zeta_j \quad \text{since} \quad H_{u_{i,j}} (\phi_i \phi_j)^{-1} \leq 0 \\
= \sum_{i,j} H_{u_{i,j}} \zeta_i \zeta_j,
\]
which finishes the proof.

For the reverse implication, we assume the system orientable and consider a stable solution \( u \). We shall follow ideas of Ghoussoub-Gui in \([11]\) (see also Berestycki-Caffarelli-Nirenberg in \([6]\)) to show that \( u \) is pointwise stable.

Define for each \( R > 0 \),
\[
\lambda_1(R) := \min \left\{ \left( \lambda_i \right)_{i=1}^n \in H^1_0(B_R(0)) \mid 0 \right\} \left\{ \sum_i \int_{B_R(0)} |\nabla \zeta_i|^2 + \sum_{i,j} \int_{B_R(0)} H_{u_{i,j}} \zeta_i \zeta_j, \quad \sum_i \int_{B_R(0)} \zeta_i^2 = 1 \right\}.
\]
Since \( u \) is a stable solution, we have that \( \lambda_1(R) \geq 0 \) and there exist eigenfunctions \( \zeta_i^R \) such that
\[
\begin{cases}
\Delta \zeta_i^R = \sum_j H_{u_{i,j}} \zeta_j^R - \lambda_1(R) \zeta_i^R, & \text{if } |x| < R, \\
\zeta_i^R = 0, & \text{if } |x| = R.
\end{cases}
\]
Since the system is orientable, there exists \((\theta_k)_{k=1}^n\) such that \( H_{u_{i,j}} \theta_i \theta_j \leq 0 \). We can then use the signs of the \( \theta_k \)'s to assign signs for the eigenfunctions \( \zeta_i^R \) so that they satisfy
\[
H_{u_{i,j}} \zeta_i^R \zeta_j^R \leq 0.
\]
For that it suffices to replace \( \zeta_i^R \) with \( sgn(\theta_i)|\zeta_i^R| \) if need be. We can also normalize them so that
\[
\sum_k |\zeta_i^R(0)| = 1.
\]
Note that \( \lambda_1(R) \downarrow \lambda_1 \geq 0 \) as \( R \to \infty \). Define \( \chi_i^R := sgn(\zeta_i^R) \zeta_i^R \) and multiply system \((27)\) with \( sgn(\zeta_i^R) \) to get that
\[
\begin{cases}
\Delta \chi_i^R = H_{u_{i,j}} \chi_i^R - \sum_{j \neq i} sgn(H_{u_{i,j}}) H_{u_{i,j}} \chi_j^R - \lambda_1(R) \chi_i^R, & \text{if } |x| < R, \\
\chi_i^R = 0, & \text{if } |x| = R.
\end{cases}
\]
Note that to get (33) we have used (28), i.e., $\text{sgn}(\zeta_R^i) = -\text{sgn}(H_{u,u_i})\text{sgn}(\zeta_R^i)$. Since now $\chi_R^i$ is a nonnegative solution for (30), Harnack’s inequality yields that for any compact subset $K$, $\max_K |\chi_R^i| \leq C(K) \min_K |\chi_R^i|$ for all $i = 1, \ldots, m$ with the latter constant being independent of $\chi_R^i$. Standard elliptic estimates also yield that the family $(\chi_R^i)_R$ have also uniformly bounded derivatives on compact sets. It follows that for a subsequence $(R_k)_k$ going to infinity, $(\chi_R^{i_k})_k$ converges in $C^2_\text{loc}(\mathbb{R}^N)$ to some $\chi_i \in C^2(\mathbb{R}^N)$ and that $\chi_i \geq 0$. From (30) we see that $\phi_i$ satisfy (11) and that $H_{u_i,u_j} \phi_j \phi_i \leq 0$ for $i < j$, which means that $u$ is a pointwise stable solution.

\section{De Giorgi type results}

We first establish a geometric Poincaré inequality for stable solutions of system (6), which will enable us to obtain De Giorgi type results but also certain rigidity properties on the gradient of the solutions.

\textbf{Theorem 3.} Assume that $m, N \geq 1$ and $\Omega \subset \mathbb{R}^N$ is an open set. Then, for any $\eta = (\eta_i)_{i=1}^m \subset C^1_c(\Omega)$, the following inequality holds for any classical solution $u \in C^2(\Omega)$ of (6)

$$
\sum_i \int_\Omega |\nabla u_i|^2|\nabla \eta_i|^2 \geq \sum_i \int_{\nabla u_i \neq 0} (|\nabla u_i|^2 A_i^2 + |\nabla T|\nabla u_i|^2) \eta_i^2 + \sum_{i \neq j} \int_\Omega (\nabla u_i \cdot \nabla u_j \eta_i^2 - |\nabla u_i||\nabla u_j|\eta_i \eta_j) H_{u_i,u_j},
$$

where $\nabla_T$ stands for the tangential gradient along a given level set of $u_i$ and $A_i^2$ for the sum of the squares of the principal curvatures of such a level set.

\textbf{Proof:} Let $\eta = (\eta_1, \ldots, \eta_m)$ and $\eta_i \in C^1_c(\Omega)$. Test the stability inequality (10) with $\zeta_i = |\nabla u_i|\eta_i$ to get

$$
0 \leq \sum_i \int_\Omega |\nabla (|\nabla u_i|\eta_i)|^2 + \sum_{i \neq j} \int_\Omega H_{u_i,u_j} |\nabla u_i||\nabla u_j|\eta_i \eta_j
$$

$$
= \sum_i \int_\Omega |\nabla |\nabla u_i||^2 \eta_i^2 + \sum_i \int_\Omega |\nabla \eta_i|^2 |\nabla u_i|^2 + \frac{1}{2} \sum_i \int_{\mathbb{R}^N} |\nabla u_i|^2 \cdot |\nabla \eta_i|^2
$$

$$
+ \sum_i \int_\Omega H_{u_i,u_j} |\nabla u_i|^2 \eta_i^2 + \sum_{i \neq j} \int_\Omega H_{u_i,u_j} |\nabla u_i||\nabla u_j|\eta_i \eta_j.
$$

Differentiate the $i^{th}$ equation of (6) with respect to $x_k$ for each $i = 1, 2, \ldots, m$ and multiply with $\partial_k u$ to get

$$
\partial_k u_i \Delta \partial_k u_i = \sum_j H_{u_i,u_j} \partial_k u_j \partial_k u_i = H_{u_i,u_j} |\partial_k u_i|^2 + \sum_{j \neq i} H_{u_i,u_j} \partial_k u_i \partial_k u_j.
$$

Multiply both sides with $\eta_i^2$ and integrate by parts to obtain

$$
\int_\Omega H_{u_i,u_j} |\partial_k u_i|^2 \eta_i^2 = \int_\Omega \partial_k u_i \Delta \partial_k u_i \eta_i^2 - \sum_{j \neq i} \int_{\mathbb{R}^N} H_{u_i,u_j} \partial_k u_i \partial_k u_j \eta_i^2
$$

$$
= - \int_\Omega |\nabla \partial_k u_i|^2 \eta_i^2 - \frac{1}{2} \int_\Omega |\nabla \partial_k u_i|^2 \cdot \eta_i^2 - \sum_{j \neq i} \int_\Omega H_{u_i,u_j} \partial_k u_i \partial_k u_j \eta_i^2.
$$
By summing over the index \( k \), we obtain
\[
\int_{\Omega} H_{u,u_i}|\nabla u_i|^2 \eta_i^2 = -\sum_k \int_{\Omega} |\nabla \partial_k u_i|^2 \eta_i^2 - \frac{1}{2} \int_{\Omega} \nabla|\nabla u_i|^2 \cdot \nabla \eta_i^2
\]
\[
- \sum_{k,j \neq i} \int_{\Omega} H_{u,u_j} \partial_k u_i \partial_k u_j \eta_i^2.
\] (34)

Combine (33) and (34) to get
\[
\sum_i \int_{\Omega} |\nabla \eta_i|^2 |\nabla u_i|^2 \geq \sum_i \int_{|\nabla u_i| \neq 0} \left( \sum_k |\nabla \partial_k u_i|^2 - |\nabla|\nabla u_i|^2 \right) \eta_i^2
\]
\[
+ \sum_{i \neq j} \int_{\Omega} (\nabla u_i \cdot \nabla u_j \eta_i^2 - |\nabla u_i||\nabla u_j| \eta_i \eta_j) H_{u,u_j}.
\]

According to formula (2.1) given in [17], the following geometric identity between the tangential gradients and curvatures holds. For any \( w \in C^2(\Omega) \)
\[
\sum_{i=1}^N |\nabla \partial_k w|^2 - |\nabla|\nabla w||^2 = \begin{cases} 
|\nabla w|^2 (\sum_{i=1}^{N-1} \kappa_i^2) + |\nabla_T|\nabla w||^2 & \text{for } x \in \{|\nabla w| > 0 \cap \Omega \}, \\
0 & \text{for a.e. } x \in \{|\nabla w| = 0 \cap \Omega \},
\end{cases}
\] (35)

where \( \kappa_i \) are the principal curvatures of the level set of \( w \) at \( x \) and \( \nabla_T \) denotes the orthogonal projection of the gradient along this level set. In light of this formula, we finally get (32).

\[\text{Remark 1. Note that for the case of } m = 1 \text{ the use of (32) and of } \zeta = |\nabla u| \eta \text{ in the stability (or semi-stability) condition (17) was first exploited by Sternberg and Zumbrun [17] to study semilinear phase transitions problems. Later on, Farina, Sciunzi, and Valdinoci [10] used it to reprove the De Giorgi’s conjecture in dimension two, and Cabré used it (see Proposition 2.2 in [8]) to prove the boundedness of extremal solutions of semilinear elliptic equations with Dirichlet boundary conditions on a convex domain up to dimension four.}\]

Here is an application of the above geometric Poincaré inequality for stable solutions of (6).

**Theorem 4.** Any bounded stable solution \( u \) of an orientable system (6) in \( \mathbb{R}^2 \) is one-dimensional. Moreover, if \( H_{u,u_j} \) is not identically zero, then for \( i \neq j \),
\[
\nabla u_i = C_{i,j} \nabla u_j \quad \text{for all } x \in \mathbb{R}^2,
\] (36)

where \( C_{i,j} \) are constants whose sign is opposite to the one of \( H_{u,u_j} \).

**Proof:** Fix the following standard test function
\[
\chi(x) := \begin{cases} 
\frac{1}{\log \frac{|x|}{\log R}}, & \text{if } |x| \leq \sqrt{R}, \\
\frac{\log \frac{|x|}{\log R}}{\log R}, & \text{if } \sqrt{R} < |x| < R, \\
0, & \text{if } |x| \geq R.
\end{cases}
\]

Since the system (6) is orientable, there exist nonzero functions \( \theta_k \in C^1(\mathbb{R}^N), \ k = 1, \ldots, m \), which do not change sign such that
\[
H_{u,u_i} \theta_i \theta_j \leq 0, \quad \text{for all } i, j \in \{1, \cdots, m\} \text{ and } i < j.
\] (37)

Consider \( \eta_k := \text{sgn}(\theta_k) \chi \) for \( 1 \leq k \leq m \), where again \( \text{sgn}(x) \) is the Sign function. The geometric Poincaré inequality (32) yields
\[
\int_{B_R \setminus B_{\sqrt{R}}} \sum_i |\nabla u_i|^2 |\nabla \chi|^2 \geq \sum_i \int_{|\nabla u_i| \neq 0} (|\nabla u_i|^2 \kappa_i^2 + |\nabla_T|\nabla u_i||^2) \chi^2
\]
\[
+ \sum_{i \neq j} \int_{\mathbb{R}^N} (\nabla u_i \cdot \nabla u_j - \text{sgn}(\theta_i) \text{sgn}(\theta_j) |\nabla u_i||\nabla u_j|) H_{u,u_j} \chi^2 = I_1 + I_2.
\] (38)
Note that $I_1$ is clearly nonnegative. Moreover, (37) yields that $H_{u_i u_j} \text{sgn}(\theta_i) \text{sgn}(\theta_j) \leq 0$ for all $i \neq j$, and therefore, $I_2$ can be written as

$$I_2 = \sum_{i \neq j} \int_{\mathbb{R}^N} (\text{sgn}(H_{u_i u_j}) \nabla u_i \cdot \nabla u_j + |\nabla u_i| |\nabla u_j|) H_{u_i u_j} \text{sgn}(H_{u_i u_j}) \chi^2,$$

which is also nonnegative.

On the other hand, since

$$\int_{B_R \setminus B_{\frac{3}{4}R}} \sum_i |\nabla u_i|^2 |\nabla \chi|^2 \leq C \left\{ \begin{array}{ll}
\frac{1}{\log^2 R} \frac{1}{R^{N-2} + R^{(N-2)/2}}, & \text{if } N = 2, \\
\frac{1}{|N-2| \log^2 R}, & \text{if } N \neq 2,
\end{array} \right.$$

one can see that in dimension two the left hand side of (38) goes to zero as $R \to \infty$. Since $I_1 = 0$, one concludes that all $u_i$ for $i = 1, \cdots, m$ are one-dimensional and from the fact that $I_2 = 0$, provided $H_{u_i u_j}$ is not identically zero, we obtain that for all $x \in \mathbb{R}^2$,

$$-\text{sgn}(H_{u_i u_j}) \nabla u_i \cdot \nabla u_j = |\nabla u_i| |\nabla u_j|,$$

which completes the proof of the theorem.

Theorem 5. Conjecture (2) holds for $N \leq 3$.

Proof: Let again $\phi_i := \partial_N u_i$ and $\psi_i := \nabla u_i \cdot \eta$ for any fixed $\eta = (\eta', 0) \in \mathbb{R}^{N-1} \times \{0\}$ in such a way that $\sigma_i := \frac{\psi_i}{\phi_i}$ is a solution of system (13) for $h_{i,j}(x) = H_{u_i u_j}(x, \phi_j(x))$ and $f$ to be the identity. Since $|\nabla u_i| \in L^\infty(\mathbb{R}^N)$, we have $||\phi_i \sigma_i||_{L^\infty(\mathbb{R}^N)} < \infty$.

In dimension $N = 2$, assumption (12) holds and Proposition 1 then yields that $\sigma_2$ is constant, which finishes the proof as argued before.

In dimension $N = 3$, we shall follow ideas used by Ambrosio-Cabré [4] and Alberti-Ambrosio-Cabré [5] in the case of a single equation. We first note that $u$ being $H$-monotone means that $u$ is a stable solution of (3). Moreover, the function $v(x_1, x_2) := \lim_{x_3 \to \infty} u(x_1, x_2, x_3)$ is also a bounded stable solution for (4) in $\mathbb{R}^2$. Indeed, it suffices to test (10) on $\zeta_k(x) = \eta_k(x') \chi_k(x_N)$ where $\eta_k \in C^1_c(\mathbb{R}^{N-1})$ and $\chi_k \in C^1_c(\mathbb{R})$ is defined as

$$\chi_k(t) := \begin{cases} 
1, & \text{if } R + 1 < t < 2R + 1, \\
0, & \text{if } t < R \text{ or } t > 2R + 2,
\end{cases}$$

for $R > 1$, $0 \leq \chi_k \leq 1$ and $0 \leq \chi_k' \leq 2$. Note also that since $u$ is an $H$-monotone solution, the system (3) is then orientable. It follows from Theorem 4 that $v$ is one dimensional and consequently the energy of $v$ in a two-dimensional ball of radius $R$ is bounded by a multiple of $R$, which yields that

$$\limsup_{t \to \infty} E(u^t) \leq CR^2,$$

where here $u^t(x') := u(x', x_n + t)$ for $t \in \mathbb{R}$ and $E_R(u) = \int_{B_R} \frac{1}{2} |\nabla u|^2 + H(u) - c_u d\mathbf{x}$ for $c_u := \inf H(u)$.

To finish the proof, we shall show that

$$\int_{B_R} |\nabla u|^2 \leq CR^2. \quad (40)$$

Note that shifted function $u^t$ is also a bounded solution of (4) with $|\nabla u^t| \in L^\infty(\mathbb{R}^N)$, i.e.,

$$\Delta u^t = \nabla H(u^t) \text{ in } \mathbb{R}^N,$$

and also

$$\partial_t u^t_i > 0 > \partial_t u^t_j \text{ for all } i \in I \text{ and } j \in J \text{ and in } \mathbb{R}^N. \quad (42)$$

Since $u^t_i$ converges to $v_i$ in $C^1_{loc}(\mathbb{R}^N)$ for all $i = 1, \cdots, m$, we have

$$\lim_{t \to \infty} E(u^t) = E(v).$$
Now, we claim that the following upper bound for the energy holds.

\[
E_R(u) \leq E_R(u^t) + M \int_{\partial B_R} \left( \sum_{i \in I} (u_i^t - u_i) + \sum_{j \in J} (u_j - u_j^t) \right) dS \quad \text{for all} \quad t \in \mathbb{R}^+ ,
\]

where \( M = \max_i \| \nabla u_i \|_{L^\infty(\mathbb{R}^N)} \). Indeed, by differentiating the energy functional along the path \( u^t \), one gets

\[
\partial_t E_R(u^t) = \int_{\partial B_R} \nabla u^t \cdot \nabla (\partial_t u^t) + \int_{B_R} \nabla H(u^t) \partial_t u^t ,
\]

where \( \nabla H(u^t) \partial_t u^t = \sum_i H_{u_i}(u^t) \partial_t u_i^t \). Now, multiply (41) with \( \partial_t u^t \), to obtain

\[
- \int_{\partial B_R} \nabla u^t \cdot \nabla (\partial_t u^t) + \int_{\partial B_R} \partial_t u_i^t \partial_t u^t = \int_{B_R} \nabla H(u^t) \partial_t u^t .
\]

From (45) and (44) we obtain

\[
\partial_t E_R(u^t) = \int_{\partial B_R} \partial_t u_i^t \partial_t u^t = \sum_i \int_{\partial B_R} \partial_t u_i^t \partial_t u_i^t .
\]

Note that \(-M \leq \partial_t u_i^t \leq M \) and \( \partial_t u_i^t > 0 > \partial_t u_j^t \) for \( i \in I \) and \( j \in J \). Therefore,

\[
\partial_t E_R(u^t) \geq M \int_{\partial B_R} \left( \sum_{j} \partial_t u_j^t - \sum_i \partial_t u_i^t \right) dS .
\]

On the other hand,

\[
E_R(u) = E_R(u^t) - \int_{0}^{t} \partial_t E_R(u^s) ds \\
\leq E_R(u^t) + M \int_{0}^{t} \int_{\partial B_R} \left( \sum_{i} \partial_t u_i^s - \sum_j \partial_t u_j^s \right) dS ds \\
= E_R(u^t) + M \int_{\partial B_R} \left( \sum_{i} (u_i^t - u_i) + \sum_j (u_j - u_j^t) \right) dS .
\]

To finish the proof of the theorem just note that \( u_i < u_i^t \) and \( u_j^t < u_j \) for all \( i \in I, j \in J \) and \( t \in \mathbb{R}^+ \).

Moreover, from (39) we have \( \lim_{t \to \infty} E_R(u^t) \leq CR^2 \). Therefore, (48) yields

\[
E_R(u) \leq C |\partial B_R| \leq CR^2 ,
\]

and we are done. \( \square \)

The above proof suggests that –just as in the case of a single equation– any \( H \)-monotone solution \( u \) of (50) must satisfy the following estimate

\[
\int_{B_R} |\nabla u|^2 \leq CR^{N-1} \quad \text{for any} \quad R > 1 ,
\]

for some constant \( C > 0 \). This can be done in the following particular case.

**Theorem 6.** If \( u \) is a bounded \( H \)-monotone solution of (50) such that for \( i = 1, \ldots, m \),

\[
\lim_{x_N \to \infty} u_i(x', x_N) = a_i, \quad \forall x = (x', x_N) \in \mathbb{R}^{N-1} \times \mathbb{R}
\]

where \( a_i \) are constants, then

\[
E_R(u) = \int_{B_R} \frac{1}{2} |\nabla u|^2 + H(u) - H(a) dx \leq CR^{N-1} ,
\]

where \( a = \{ a_i \}_{i=1}^{m} \) and \( C \) is a positive constant independent of \( R \).
Proof: We first note the following decay on the energy of the shifted function $u^t$ as defined above,

$$\lim_{t \to \infty} E_R(u^t) = 0.$$  \hfill (51)

Indeed, since $u^t$ is convergent to a pointwise, one can see that

$$\lim_{t \to \infty} \int_{B_R} (H(u^t) - H(a)) dx \to 0.$$ 

Therefore, we need to prove that

$$\lim_{t \to \infty} \int_{B_R} |\nabla u^t_i|^2 dx \to 0.$$ 

To do so, multiply both sides of (41) with $u^t_i - a_i$ and integrate by parts to get

$$-\int_{B_R} |\nabla u^t_i|^2 + \int_{\partial B_R} \partial_{\nu} u^t_i(u^t_i - a_i) = \int_{B_R} \nabla H(u^t)(u^t_i - a_i),$$

which yields (51).

To get the energy bound in (50), one can follow the proof of the previous theorem to end up with

$$E_R(u) \leq E_R(u^t) + C|\partial B_R| \text{ for all } t \in \mathbb{R}^+.$$ 

To conclude, it suffices to send $t \to \infty$ and to use the fact that $\lim_{t \to \infty} E_R(u^t) = 0$ to finally obtain that

$$E_R(u) \leq C|\partial B_R| \leq C R^{N-1}.$$ 

**Remark 2.** Using Pohozaev type arguments one can see that

$$\Gamma_R = \frac{E_R(u)}{R^N} \text{ is increasing}$$  \hfill (52)

provided the following pointwise estimate holds:

$$|\nabla u|^2 \leq 2H(u).$$ \hfill (53)

Note that this is an extension of the pointwise estimate that Modica [13] proved in the case of a single equation. It is still not known for systems, though Caffarelli-Lin in [9] and later, Alikakos in [2] have shown, in the case where $H \geq 0$, the following weaker monotonicity formula, namely that

$$\Lambda_R = \frac{E_R(u)}{R^N} \text{ is increasing in } R.$$ \hfill (54)

**Remark 3.** The $H$-monotonicity assumption seems to be crucial for concluding that the solutions are one-dimensional. Indeed, it was shown in [1] that when $H$ is a multiple-well potential on $\mathbb{R}^2$, the system has entire heteroclinic solutions $(u,v)$, meaning that for each fixed $x_2 \in \mathbb{R}$, they connect (when $x_1 \to \pm \infty$) a pair of constant global minima of $W$, while if $x_2 \to \pm \infty$, they connect a pair of distinct one dimensional stationary wave solutions $z_1(x_1)$ and $z_2(x_1)$. Note that these convergence are even uniform, which means that the corresponding Gibbons conjecture for systems of equations is not valid in general, without the assumption of $H$-monotonicity.
