Trends of Utilization of Family Planning Methods at Divisional Headquarter Hospital of Mirpur, AJ and K

Introduction

Growing population is the burning issue adversely affecting the development and social security in the world today, mainly in Asia, South America, Africa and especially in Pakistan and our neighboring country India. Pakistan is one of the populous country with population of 190 million and a growth rate of 1.6% annually. New projections released by the United Nations indicate that Pakistan is among 6th of the 10 populated countries in world and the population has been expected to exceed three hundred million by 2050. Right now, the population has been assessed to be around one hundred ninety million. In year 2030, the population would be around 244 million, and by 2100 population could be 364 million. The population of our region is at its tremendous increase, which is alarming for both men and women. The population has been expected to exceed three hundred million by 2050. Right now, the population has been assessed to be around one hundred ninety million. In year 2030, the population would be around 244 million, and by 2100 population could be 364 million.

The population of our region is at its tremendous increase, which is alarming for both men and women. The population has been expected to exceed three hundred million by 2050. Right now, the population has been assessed to be around one hundred ninety million. In year 2030, the population would be around 244 million, and by 2100 population could be 364 million.

Millions of women for some or other reason are not using contraceptive. It is a well-known fact that the acceptance of contraception by a couple is governed by many factors such as availability of services and facilities for provision of contraceptive devices. Apart from this, various socio demographic factors such as age, sex, religion, education, income, occupation, urban/rural differences, and family size also affecting the use of contraceptives. Thus this study attempts to analyze the trends of utilization of different contraceptive methods in one year at Divisional Headquarter Hospital of Mirpur AJ & K.

Material and Methods

A retrospective record based study was performed to analyze the trends of utilization of different contraceptive methods in a year. The data was collected by analyzing the records from April 2015 to March 2016 from family planning clinic in Divisional Headquarter Hospital of Mirpur AJ & K. Inclusion criterion for this study was the individuals who used different contraceptive methods at family planning clinic. The various socio-demographic factors such as age, gender, religion, family size and utilization pattern in reference to urban and rural area were analyzed for adoption of different family planning methods. Data were analyzed using percentage algorithm.

Results and Discussion

During the one-year period, a total of 920 individuals attended the reproductive health services from April 2015 to March 2016 at family planning clinic. Among them, 92% individual utilized temporary methods and only 8% utilized permanent methods. Among temporary, out of total 299 (33%) selected intrauterine device, 233(25%) had used injectable, 191(21%) took oral contraceptive pills, and 121 (13%) selected Barrier Methods (condom). Among permanent 76 (8%) had bilateral tubal ligation and no vasectomy. Males are not convinced for male sterilization due to social pressure of family. The most contraceptive methods were used between age group 28-40 years. (Figure 1) (Table 1)

Table 1: Age wise utilization of contraceptive methods in last one year.

| Year               | 18-25 Year(%) | 26-30 Year(%) | 31-35 Year(%) | >35 Year(%) | Total |
|--------------------|---------------|---------------|---------------|-------------|-------|
| April 2015-March 2016 | 920           |               |               |             |       |

The present study revealed that 92% individuals accepted temporary methods for contraception whereas only 8% chosen permanent methods. Out of 92%, majority of individuals (33%) preferred the use of IUCD and followed by injectable contraceptives by 25% and then oral contraceptive pill (21%). Out of permanent methods, utilization of tubectomy with no vasectomy was adopted by 8% of subjects. Studies conducted by Sajid A., Maik S. at Lady Alitchon Hospital, Lahore, 2010 and another study by Seema Bibi, Amna Memon in two districts of Sindh, shown contrary findings indicating that tubal ligation was the least common method of family planning followed by condom and IUCD which may be due to social customs, fear and cultural misbelieves about accepting IUCD of that particular area (5, 6). A study by Rozina Mustafa and Haleema A Hashmi in Karachi and another in urban population of North India in 2008 had found that condom was the most common method, which is also in contrast to our study. This could be due to high risk of failure of condom as compared to IUCD with which failure rate is low. The interesting finding emerging out of this study is that adoption of injectable methods was more as compared to oral contraceptives. This is most probably due to fear of forgetting taking oral tablets and burden of remembering to take tablets daily. Multicentric study shows methods for contraception use differs country-to-county for conferring to their cultural and traditions values in terms of total use and the sorts of methods used. Around the globe, a total of 63% of married women ages 15 to 49 years use a contraceptive method: 57% use a modern methods. While more women in much developed countries use contraception, in the most under developed countries, less than one in five married women use any of the method. Contraceptive use has risen steadily over time in most developing countries, as is the case in Colombia and Bangladesh. Still, use of family planning methods has continued stable or even dropped in others, for example Jordan and Nepal. Most popular method right now in the world is Female sterilization for the birth prevention. United Nations global survey of reproductive health declared in his statement that in married women one fifth depends on female sterilization (tubal ligation). In China, India and Brazil more than one third of all married women have been sterilized for birth control.

Conclusions

In present study, trend of utilization was found most common for temporary (92) as compared to permanent (8%). Female are mostly using the contraception. Male should be counseled for vasectomy as it is simple procedure as compared to female tubectomy. All resources like Media Maslanas in Mosques and leaders should be involved to avoid the myths. More and more camps should be arranged to provide education and awareness to the both rural as well as urban population for benefits of use of contraception.
