AN UPPER BOUND FOR THE LENGTH OF A TRAVELING SALESMAN PATH IN
THE HEISENBERG GROUP

SEAN LI AND RAANAN SCHUL

Abstract. We show that a sufficient condition for a subset $E$ in the Heisenberg group (endowed with the Carnot-Carathéodory metric) to be contained in a rectifiable curve is that it satisfies a modified analogue of Peter Jones’s geometric lemma. Our estimates improve on those of [FPF07], allowing for any power $r < 4$ to replace the power 2 of the Jones-β-number. This complements in an open ended way our work in [LS], where we showed that such an estimate was necessary, however with the power $r = 4$.

1. Introduction

Let $\mathbb{H}$ denote the Heisenberg group, endowed with the Carnot-Carathéodory distance and $E \subseteq \mathbb{H}$ be any subset. Then we denote

$$\beta_{E, \mathbb{H}}(B) = \inf_L \sup_{x \in E \cap B} \frac{d(x, L)}{\text{diam}(B)},$$

with the infimum is taken over all horizontal lines $L$ (to be defined in the next section). If it is clear from the context which set $E$ we are referring to, we will omit it from the notation and write $\beta_B$.

In this paper we prove the following theorem.

**Theorem A.** Let $r < 4$ be fixed. There is a constant $C = C(r) > 0$ such that for any set $E \subseteq \mathbb{H}$ if

$$\text{diam}(E) + \int_0^\infty \beta_{E, \mathbb{H}}(B(x, t))^r \frac{dt}{t^4} \text{d}\mathcal{H}^4(x) < \infty,$$

then there exists a rectifiable curve $\Gamma \supseteq E$ such that

$$\mathcal{H}^1(\Gamma) \leq C \left( \text{diam}(E) + \int_0^\infty \beta_{E, \mathbb{H}}(B(x, t))^r \frac{dt}{t^4} \text{d}\mathcal{H}^4(x) \right). \quad (1)$$

We do not know if Theorem A is still true when $r = 4$, but we do know that it is almost optimal: in [LS] we showed the following.

**Theorem B.** There is a constant $C > 0$ such that for any rectifiable curve $\Gamma$ the following holds. We have

$$\int_0^\infty \beta_{\Gamma, \mathbb{H}}(B(x, t))^4 \frac{dt}{t^4} \text{d}\mathcal{H}^4(x) \leq C \mathcal{H}^1(\Gamma). \quad (2)$$

In $\mathbb{R}^d$, the analogous theorems hold with the same power $r = 2$ for both Theorem A and B ($t^4$ is replaced by $t^n$ as $n$ is the Hausdorff dimension of $\mathbb{R}^n$; affine lines replace horizontal lines) [Jon90, Oki92]. If one discretizes the integral to a sum in an appropriate way, the same holds for an infinite dimensional Hilbert space [Sch07c], again, with $r = 2$. In a general metric space, with no assumptions on the set $E$, there is an analogue of Theorem A [Han03], however the analogue of Theorem B is false in that setting [Sch07a]. If one adds the assumption that $E$ is 1-Ahlfors-regular (i.e. it supports a measure with linear upper and lower bounds on...
its growth) then, in this general metric setting analogues of both Theorem A and B hold [Hah07, Sch07b]. Finally we note in the that extensive work on the Euclidean case had been done by many people in the setup where one approximates with $k$-planes rather than lines, and that there is a very deep connection between these geometric questions and singular integral operators. See for example [Paj02, DS91, DS93, Tel12] and references therein.

The curve in Theorem A may be constructed in an algorithmic way. In fact, up to a natural modification of the constants used (and the metric), this curve is constructed in [FFP07]. The authors there get the estimate $|B|$ for $r \leq 2$. Several years after [FFP07] was published, an example was constructed of a finite length curve such that the right hand side of $|B|$, with $r \leq 2$, is infinite [Jou90]. With a minor modification (taking the parameters of the construction to be $\theta_k = \frac{\pi}{2p}$ for $p > 1/2$ instead of $p = 1$), this example remained a valid counterexample for all $r < 4$ and so suggested that one may be able to improve on [FFP07]. Indeed our contribution in this note is to improve upon the estimates of [FFP07] in a non-trivial fashion, and as a consequence to extend the range of valid $r$ by adding the range $(2, 4)$. The fact that one may improve upon the power $r = 2$ came from [Li14a], which gave a parametric version of Theorem B with power different from 2. In the same paper, it was also shown that the parametric analogue of $r$ is related to the Markov convexity of $\mathbb{H}$, which was recently calculated to be 4 in [Li14b].

Previous proofs of statements like Theorem A used the farthest insertion algorithm along with a curvature inequality of the form

$$d(a, b) + d(b, c) - d(a, c) \leq \beta(B)^p \text{diam}(B)$$

where $B$ is some ball of radius $r$ and $a, b, c \subset E \cap B$ are points whose mutual distances are all on the order of $r$. Here, $\beta(B)$ depends on the context of the problem.

The curve is then built in an iterative fashion. Letting $\Delta_k$ be a $2^{-k}$-net of $E$ that was connected by a polygonal curve $\Gamma_k$, one builds $\Gamma_{k+1}$ by adding and deleting segments of $\Gamma_k$ in a clever way to include $\Delta_{k+1}$. An inequality like (3) allows the sum of the telescoping series $\ell(\Gamma_{k+1}) - \ell(\Gamma_k)$ to be bounded by the Carleson summation of the $\beta$-numbers. This allows us to take an appropriate limit to get the curve $\Gamma$ that we need. This technique was first used in [Jon90].

In [FFP07], the authors showed that the $r = 2$ version of Theorem A is true by proving the inequality

$$d(a, b) + d(b, c) - d(a, c) \leq C\beta_\text{H}(B)^2 \text{diam}(B)$$

and then applying the farthest insertion algorithm with (4). Here, $a, b, c$ are points in $E \cap B$ that are spread out far enough. Thus, the first obvious attempt would be to improve this inequality to get a higher power of the $\beta_\text{H}(B)$. However, this is impossible. We discuss the geometry of the Heisenberg group in the next section, so it may be useful to review that before reading on.

Consider the points $a = (-1, 0, 0), b = (0, 0, \varepsilon), c = (1, 0, 0)$. It is straightforward to calculate that there exists some absolute constant $c_1 > 0$ so that

$$d(a, b) + d(b, c) - d(a, c) \geq c_1\varepsilon^2.$$ 

However, one can see that if we let $L = \{(1 - \frac{t}{2})t, \frac{\varepsilon}{2}t, 0 : t \in \mathbb{R}\}$ be a horizontal line, then there exists some absolute constant $c_2 > 0$ so that

$$\max\{d(a, L), d(b, L), d(c, L)\} \leq c_2\varepsilon.$$ 

This is because if we set $a' = (1 - \frac{\varepsilon}{2}, \frac{\varepsilon}{2}, 0), c' = (\frac{\varepsilon}{2} - 1, -\frac{\varepsilon}{2}, 0)$ to be points in $L$, then $\max\{d(a, a'), d(c, c')\} < c_2\varepsilon$. Thus, by taking $\varepsilon \to 0$, we see that the power 2 in (4) cannot be improved, at least in this generality.

What we will show is that for any $p < 4$, ball $B \subset \mathbb{H}$, and points $a, b, c \in E \cap B$ that are well spread out, if $E \cap B$ is sufficiently connected (the exact condition is given in the assumptions of Proposition 4.1), there is some other ball $F_1(B) \subset \mathbb{H}$ for which

$$d(a, b) + d(b, c) - d(a, c) \leq C_p\beta_\text{H}(F_1(B))^p \text{diam}(F_1(B)).$$

This ball $F_1(B)$ may be smaller than $B$ and may not actually be contained in $B$, but it cannot be too much smaller and cannot be too far away from $B$. In fact the radius of $F_1(B)$ is controlled from below by a function of $\beta_\text{H}(B)$ (times that of $B$), and its distance from $B$ is a multiple of the diameter of $B$. Thus, we can control how many times each ball $B'$ is used as a $F_1(B)$. In the case when $E$ is not sufficiently connected enough to use (4), then the disconnection will enable us to use an accounting trick to show that (4) is sufficient to
handle this case. This search for balls with better \( \beta \) properties deviates from the proofs of previous versions of Theorem A and is what enables us to improve on the \( r = 2 \) power.

An obvious question is whether Theorem A is true for \( r = 4 \). The fact that \( r < 4 \) is crucially used in two parts of the construction of this paper. In finding \( F_1(B) \), one has to do iterative searches for balls with progressively better properties. That \( r < 4 \) guarantees that we only need to do \( O(1) \) searches. This allows us to control the constant in \([3]\). Another place where \( r < 4 \) is used in in controlling the number of times a ball \( B' \) can be some \( F_1(B) \) for some other ball \( B \). We get that the number of occurrences is some log factor of \( \beta_H(B) \). That \( r < 4 \) allows us to remove these log terms by first proving the statement for some power \( r' \in (r, 4) \) and then relaxing the power to \( r' \).

Thus, we leave unanswered the question Is there a constant \( C = C(4) \) so that \( H \) holds for \( r = 4 \)?

In the next section, we review some facts about the Heisenberg group and establish the notation for the rest of the paper. In section 3, we will prove the lemmas needed for our main proposition, the proof of which will be given in section 4. In section 5, we show how to adapt the construction of \([FFP07]\) to use the proposition of Section 4 to prove Theorem A.

2. Preliminaries

Following \([FFP07]\), we will say that the Heisenberg group is the 3-dimensional Lie group \( \mathbb{H} = (\mathbb{R}^3, \cdot) \) where the group multiplication is

\[
(x, y, z) \cdot (x', y', z') = (x + x', y + y', z + z' + 2(xy' - x'y)).
\]

There is a natural path metric on \( \mathbb{H} \) that we now describe. Using the fact that group multiplication is smooth, we can define \( \Delta \), a left-invariant subbundle of the tangent bundle so that \( \Delta_0 \) is the \( xy \)-plane in \( \mathbb{R}^3 \) and \( \Delta_g = (L_g)_*\Delta_0 \) for \( g \in \mathbb{H} \) where \( L_g \) is the \( \mathbb{H} \to \mathbb{H} \) map that is left multiplication by \( g \). We can similarly use \( L_g \) to endow \( \Delta \) with a left-invariant field of inner products \( \langle \cdot, \cdot \rangle_g \). Given \( x, y \in \mathbb{H} \), we can now define the Carnot-Carathéodory distance between \( x \) and \( y \) to be

\[
d_{cc}(x, y) := \left\{ \int_a^b \langle \gamma'(t), \gamma'(t) \rangle_{\gamma(t)} dt : \gamma \in C^1([a, b]; \mathbb{H}), \gamma(a) = x, \gamma(b) = y, \gamma'(t) \in \Delta_{\gamma(t)} \right\}.
\]

It is natural to ask whether there always exists such \( \gamma \in C^1([a, b]; \mathbb{H}) \) such that \( \gamma'(t) \in \Delta_{\gamma(t)} \). Chow’s theorem tells us that such \( C^1 \) curves always exist in \( \mathbb{H} \) (see \( e.g. \) \([Mon02]\)). Continuous paths that satisfy \( \gamma'(t) \in \Delta_{\gamma(t)} \) (almost everywhere) are called horizontal paths. As we are taking the Riemannian distance in a subclass of \( C^1 \) paths connecting two points, this geometry is sometimes called subriemannian geometry.

It is well known that a horizontal curve \( \gamma = (\gamma_x, \gamma_y, \gamma_z) : I \to \mathbb{H} \) satisfies the following identity

\[
\gamma_z(b) - \gamma_z(a) - 2(\gamma_x(a)\gamma_y(b) - \gamma_x(b)\gamma_y(a)) = 2 \int_a^b (\gamma_x(t)\gamma_y'(t) - \gamma_x'(t)\gamma_y(t)) \ dt, \quad \forall a, b \in I.
\]

Thus, the change in \( z \)-coordinate of a horizontal curve as viewed in the group product is equal to four times the algebraic area swept by \( (\gamma_x, \gamma_y) \) when viewed as a curve in \( \mathbb{R}^2 \).

While the Carnot-Carathéodory metric is a well defined path metric, it is not so easy to explicitly compute distances between points based on their coordinates. We now introduce a new metric, the Koranyi metric. It has the advantage that computing distances in terms of coordinate data is explicit. We let

\[
N : \mathbb{H} \to \mathbb{R} \quad (x, y, z) \mapsto ((x^2 + y^2)^2 + z^2)^{1/4}
\]
denote the Koranyi norm. It then defines a left-invariant metric on \( \mathbb{H} \) via \( d(g, h) = N(g^{-1}h) \). It is well known that this metric is biLipschitz equivalent to the Carnot-Carathéodory metric \([Cyg84]\). We have that \( d(x, y) \leq d_{cc}(x, y) \) as \( d(x, y) = d_{cc}(x, y) \) whenever \( x \) and \( y \) are on a horizontal line and so the Koranyi norm does not decrease length in horizontal paths. For simplicity, we will assume the non-sharp (see (1.4) in \([BHT06]\)) lower bound

\[
d(x, y) \geq \frac{1}{2} d_{cc}(x, y).
\]
An important property of \( \mathbb{H} \) is that it admits a family of dilation automorphisms. Specifically, for each \( \lambda > 0 \), we can define the automorphism
\[
\delta_\lambda : \mathbb{H} \to \mathbb{H}
\]
\[
(x, y, z) \mapsto (\lambda x, \lambda y, \lambda^2 z).
\]
These dilations scale the metric, that is, \( d_{cc}(\delta_\lambda(x), \delta_\lambda(y)) = \lambda d_{cc}(x, y) \). This can be verified by looking at the Jacobian of \( \delta_\lambda \) and the remembering how the Carnot-Carathéodory metric is defined. It is immediately verified by looking at the expression of the Koranyi norm that \( \delta_\lambda \) also scales the Koranyi metric.

Rotations around the \( z \)-axis comprise a set of isometric automorphisms of \( \mathbb{H} \). This follows from looking at the formulas of the Koranyi norm and group multiplication and seeing that \( xy' - x'y \) is just a cross product, which is invariant under rotations.

The Heisenberg group is known to be geometrically doubling. That is, there exists some \( M > 0 \) so that any ball \( B(x, r) \subset \mathbb{H} \) can be covered by \( M \) balls of radius \( \frac{r}{2} \). The point is that \( M \) can be chosen uniformly for all \( x \in \mathbb{H} \) and \( r > 0 \). This follows from the fact that the Lebesgue measure on \( \mathbb{R}^3 \) a Haar measure of \( \mathbb{H} \) and balls of \( \mathbb{H} \) grow like \( r^4 \). A standard volume packing argument then gives that \( \mathbb{H} \) is geometrically doubling. That the Lebesgue measure on \( \mathbb{R}^3 \) is a Haar measure for \( \mathbb{H} \) can be seen from the fact that the linear parts of the affine transforms in \( \mathbb{R}^3 \) that correspond to group translations in \( \mathbb{H} \) are volume preserving. The growth of balls comes from the anisotropic scaling of the dilations.

Another important feature of the Heisenberg group is the existence of a distinguished family of curves called horizontal lines. Before we define horizontal lines, we first define horizontal elements of \( \mathbb{H} \). An element \( g \in \mathbb{H} \) is said to be horizontal if \( g \) lies on the \( xy \)-plane. For such horizontal elements, we can extend \( \delta_\lambda \) to all \( \lambda \in \mathbb{R} \) to get \( \delta_\lambda(x, y, 0) = (tx, ty, 0) \). The horizontal lines are subsets of the form \( \{g \cdot \delta_t(h) : t \in \mathbb{R}\} \) where \( g, h \in \mathbb{H} \) and \( h \) is horizontal. Horizontal lines essentially amount to horizontal curves where the tangent vector stays the same. Note that the set of horizontal lines going through a specified point in \( \mathbb{H} \) spans two dimensions instead of three as in \( \mathbb{R}^3 \). This shows that most pairs of points in \( \mathbb{H} \) cannot be joined by a horizontal line, which reflects a crucial difference between Heisenberg and Euclidean geometry.

We define the homomorphic projection
\[
\pi : \mathbb{H} \to \mathbb{R}^2
\]
\[
(x, y, z) \mapsto (x, y).
\]
It is immediately verifiable that this is 1-Lipschitz by looking at the Koranyi norm. We also define the maps
\[
\tilde{\pi} : \mathbb{H} \to \mathbb{H}
\]
\[
(x, y, z) \mapsto (x, y, 0)
\]
and
\[
NH : \mathbb{H} \to \mathbb{H}
\]
\[
g \mapsto N(g^{-1}\tilde{\pi}(g)).
\]
Note that \( \tilde{\pi} \) is not a homomorphism. The map \( NH \) gives a measurement of how nonhorizontal an element \( g \in \mathbb{H} \) is by computing the distance of \( g \) to the horizontal element “below” it.

Given subsets \( K \subseteq L \) of any metric space \( (X, d_X) \) and \( \delta > 0 \), we say \( K \) is \( \delta \)-connected in \( L \) if for each \( x, y \in K \), there exists a finite sequence \( \{z_i\}_{i=1}^n \subset L \) for which \( z_1 = x \) and \( z_n = y \) so that \( d_X(z_i, z_{i+1}) < \delta \).

Finally, we recall that a curve is a continuous map \( \gamma \) whose domain is an interval \( I \subset \mathbb{R} \). If \( \gamma \) has finite arclength then its image is called a rectifiable curve. It is a standard result that a connected set \( \Gamma \) in a doubling metric space, which satisfies \( H^1(\Gamma) < \infty \) is a rectifiable curve. See for example the appendix of \[\text{[FFP07].}\]

3. Lemmas: Future balls

Given a point \( p \in \mathbb{H} \) and a horizontal line \( L \subset \mathbb{H} \), if \( \pi(p) \notin \pi(L) \), we let \( p_L \in \mathbb{H} \) denote the point that is co-horizontal with \( p \) (i.e. \( NH(p_L^{-1}p) = 0 \)) so that \( \pi(p_L) \in \pi(L) \) and the line in \( \mathbb{R}^2 \) spanned by \( \pi(p) \) and \( \pi(p_L) \) is perpendicular to \( \pi(L) \). If \( \pi(p) \in \pi(L) \), then \( p_L = p \). It is easy to see that \( d(p_L, L) \) scales like the square root of the \( z \)-distance from \( p_L \) to \( L \). We have the following lemma.
Lemma 3.1.

\[
\frac{1}{2} \left( d(p, p_L)^4 + d(p_L, L)^4 \right)^{1/4} \leq d(p, L) \leq 2 \left( d(p, p_L)^4 + d(p_L, L)^4 \right)^{1/4}.
\]

Proof. The inequality on the right hand side is simply the triangle inequality along with Jensen’s inequality. By a rotation and translation, we may suppose that \( L \) is the \( x \)-axis and the \( x \) coordinate of \( p \) is 0. Thus, \( p = (0, y, z) \) and \( p_L = (0, 0, z) \). We have that

\[
d(p_L, L) = \inf_{t \in \mathbb{R}} (t^4 + z^2)^{1/4} = |z|^{1/2}.
\]

As \( d(p, p_L) = |y| \), we see that we get the left hand inequality if we show for all \( t \in \mathbb{R} \) that

\[
f(t) := d((t, 0, 0), (0, y, z))^4 = (t^2 + y^2)^2 + (z - 2ty)^2 \geq \frac{1}{16} (y^4 + z^2).
\]

Note that \( f(t) \geq y^4 \) always.

We have made no effort to optimize constants in this lemma. It will not be necessary to use optimal constants in this paper.

Given a horizontal line \( L \) and a point \( p \in \mathbb{H} \), we let \( P_L(p) \) denote the point in \( L \) that is just a vertical translate of \( p_L \). Sometimes we will abuse notation and treat \( P_L(p) \) as a point in \( \mathbb{R} \) corresponding to the linear isometry of \( L \) with \( \mathbb{R} \). It will be clear by context whether we mean \( P_L(p) \) as a point in \( \mathbb{H} \) or a point in \( \mathbb{R} \).

Let \( a, b \in \mathbb{H} \). We let \( \Sigma_{a,b} \) denote the algebraic area of the closed path in \( \mathbb{R}^2 \) that comes from the projection to \( \mathbb{R}^2 \) of any horizontal path in \( \mathbb{H} \) connecting \( a \) to \( b \) (so in \( \mathbb{R}^2 \) it goes from \( \pi(a) \) to \( \pi(b) \)) and then subsequently going back to \( \pi(a) \) via a straight line. Note by Heisenberg geometry that the vertical coordinate of \( a^{-1}b \) is exactly \( \Sigma_{a,b} \) and so we get that \( \Sigma_{a,b} \) is in fact independent of the chosen horizontal path in \( \mathbb{H} \). Thus, we also see that

\[
NH(a^{-1}b) = 2|\Sigma_{a,b}|^{1/2}.
\]

Given a horizontal line \( L \subset \mathbb{H} \), we let \( \Sigma_{a,b}^L \) denote the algebraic area of the following closed path in \( \mathbb{R}^2 \) (with the specified orientation) that we describe. It first goes from \( \pi(a_L) \) to \( \pi(a) \) by a straight line. Then it follows the projection to \( \mathbb{R}^2 \) of any horizontal path in \( \mathbb{H} \) connecting \( a \) to \( b \). It then goes from \( \pi(b) \) to \( \pi(b_L) \) via a straight line before finally going back to \( \pi(a_L) \) via another straight line. We easily see that \( \Sigma_{a,b}^L = \Sigma_{a,b} + T \), where \( T \) is the algebraic area of the trapezoid in \( \mathbb{R}^2 \) that starts at \( \pi(a) \) and goes to \( \pi(b) \), \( \pi(b_L) \), \( \pi(a_L) \), before finally going back to \( \pi(a) \). Thus, we see that \( \Sigma_{a,b}^L \) is also independent of the chosen horizontal curve in \( \mathbb{H} \).
Lemma 3.4. A horizontal line is a set such that
\[ NH(a_L^{-1}b_L) \leq 2|\Sigma_{a_L,b_L}|^{1/2} = 2|\Sigma_{a,b}|^{1/2} \] for any \( a, b \in \mathbb{H} \) and horizontal line \( L \subset \mathbb{H} \). A very useful property of \( \Sigma_{a,b} \) is that it is additive. That is, for \( a, b, c \in \mathbb{H} \), we have
\[ \Sigma_{a,c} = \Sigma_{a,b} + \Sigma_{b,c}. \]

Lemma 3.2. If \( a, b \in \mathbb{H} \) and \( L \subset \mathbb{H} \) is a horizontal line, then
\[ \max\{d(a, L), d(b, L)\} \ges 1/2 |\Sigma|^{1/2}. \]

Proof. Suppose that \( \max\{d(a, L), d(b, L)\} \leq \varepsilon \). Then by Lemma 3.1 we have that \( \max\{d(a_L, L), d(b_L, L)\} \leq 2\varepsilon \). Then we can write \( a_L = g y \) and \( b_L = h z \) for some \( g, h \in L \) and \( y, z \in \mathbb{Z}(\mathbb{H}) \) for which \( \max\{d(y, 0), d(z, 0)\} \leq 2\varepsilon \). It follows that \( \tilde{\pi}(a_L^{-1}b_L) = g^{-1}h \). As \( y, z \) commute with all elements of \( \mathbb{H} \), we get from (8) that
\[ |\Sigma|^{1/2} = \frac{1}{2} NH(a_L^{-1}b_L) = \frac{1}{2} d(y^{-1}g^{-1}h, g^{-1}h) = d(g^{-1}h, y^{-1}z, g^{-1}h) = \frac{1}{2} d(y, z) \leq 2\varepsilon. \]

Lemma 3.3. There exists some universal constant \( C > 0 \) so that for every \( a, b \in \mathbb{H} \) and every horizontal line \( L \subset \mathbb{H} \) we have
\[ \max\{d(a, L), d(b, L)\} \geq \frac{1}{16} \frac{NH(a^{-1}b)^2}{d(a, b)}. \]

We make the observation that the right-hand side above is independent of \( L \). Note that this says that sets of two points in \( \mathbb{H} \) can have a nonnegative \( \beta \) quantity for a ball containing them. This cannot happen in the Euclidean case.

Proof. We now fix a horizontal line \( L \). By Lemma 3.1 we see that \( d(a, L) \geq \frac{1}{2} d(a_L, L) \) and \( d(b, L) \geq \frac{1}{2} d(b_L, L) \). Thus, we are done unless \( \|\pi(b) - \pi(b_L)\| = d(b, b_L) \leq \frac{1}{8} \frac{NH(a^{-1}b)^2}{d(a, b)} \) and \( \|\pi(a) - \pi(a_L)\| = d(a, a_L) \leq \frac{1}{8} \frac{NH(a^{-1}b)^2}{d(a, b)} \). Now consider the trapezoid \( T \) in \( \mathbb{R}^2 \) defined by the points \( \pi(a), \pi(b), \pi(a_L), \pi(b_L) \). As \( \pi : \mathbb{H} \to \mathbb{R}^2 \) is 1-Lipschitz, this trapezoid has area at most \( \frac{1}{8} NH(a^{-1}b)^2 \). But
\[ |\Sigma| \geq |\Sigma_{a, b}| - |T| \geq \frac{1}{8} NH(a^{-1}b)^2. \]
Thus, Lemma 3.2 tell us that
\[ \max\{d(a, L), d(b, L)\} \geq \frac{1}{16} \frac{NH(a^{-1}b)^2}{d(a, b)}. \]
In the last inequality, we used the fact that \( NH(a^{-1}b) \leq d(a, b) \).

The next lemma says that a well-connected set that goes from the center to outside a ball and is close to a horizontal line \( L \) must have large diameter when projected onto \( L \).

Lemma 3.4. Let \( \delta < \frac{1}{100} \). Let \( B \subset \mathbb{H} \) be a ball and \( L \subset \mathbb{H} \) be a horizontal line. Suppose \( E = \{p_i\}_{i=1}^N \subset \mathbb{H} \) is a set such that
\[ p_1 = \text{Center}(B), \]
\[ d(p_1, p_N) \ges \text{rad}(B), \]
\[ d(p_i, p_{i+1}) < \delta \text{diam}(B) \]
\[ \sup_{z \in E \cap B} d(z, L) \leq \frac{1}{100} \text{diam}(B). \]
Proof. Let \( p_j \) be such that \( d(p_1, p_j) \leq \text{rad}(B) \) and \( d(p_1, p_{j+1}) > \text{rad}(B) \). Then
\[
d(p_1, p_j) \leq d(p_1, p_{j+1}) - d(p_j, p_{j+1}) > \frac{49}{100} \text{diam}(B).
\]
By (7), we have that
\[
d(p_1, P_L(p_1)) \leq \frac{4}{100} \text{diam}(B), \quad d(p_j, P_L(p_j)) \geq \frac{4}{100} \text{diam}(B).
\]
Thus,
\[
|P_L(p_1) - P_L(p_j)| = d(P_L(p_1), P_L(p_j)) \geq d(p_1, p_j) - \frac{8}{100} \text{diam}(B) \geq \frac{41}{100} \text{diam}(B).
\]

The following lemma will be crucial for the proof of Lemma 3.6.

Lemma 3.5. Let \( p < 4, \varepsilon, M, M_1, \delta > 0 \) such that
\[
\frac{1}{100} > \varepsilon > M_1 > \frac{M}{2} > 10\delta > 0, \quad \varepsilon > M.
\]
Let \( L \subset \mathbb{H} \) be a horizontal line. Suppose \( \{p_i\}_{i=1}^N \subset H \) is a sequence such that
\[
\begin{align*}
d(p_i, p_{i+1}) &< \delta, \quad \forall i \in \{1, \ldots, N-1\} \\
\max_{i \in \{1, \ldots, N\}} d(p_i, L) &\leq \varepsilon, \quad (12) \\
\|\pi(p_i) - \pi(L)\| &\leq \max_{i \in \{1, \ldots, N\}} \|\pi(p_i) - \pi(L)\| = M_1, \quad (13) \\
|P_L(p_1) - P_L(p_N)| &> \frac{500\varepsilon^2}{M}. \quad (14)
\end{align*}
\]
Then either there exists \( j \in \{1, \ldots, N\} \) so that
\[
|P_L(p_j) - P_L(p_1)| < 500\frac{\varepsilon^2}{M},
\]
\[
\|\pi(p_j) - \pi(L)\| < \frac{M_1}{2},
\]
or there exists a ball \( B' \subset \mathbb{H} \) for which \( \text{diam}(B') \geq M \) and
\[
\beta_{E}(B')^p \text{diam}(B') \geq 10^{-50}M.
\]

Proof. Suppose the first alternative is false, that is
\[
\|\pi(p_j) - \pi(L)\| \geq \frac{M_1}{2}, \quad (14)
\]
for all \( j \) such that \( |P_L(p_j) - P_L(p_1)| < 500\frac{\varepsilon^2}{M} \). We will fix an order on \( L \) so that \( P_L(p_1) - P_L(p_N) > 0 \). We may suppose by removing a tail end of the sequence \( \{p_i\} \) that \( N \) is the first index for which \( P_L(p_1) - P_L(p_N) > M\left[\frac{400\varepsilon^2}{M^2}\right]\). We then let \( \Gamma \) denote the horizontal path connecting \( p_1 \) to \( p_N \) that goes from \( p_1 \) to \( p_{i+1} \) via a subriemannian geodesic. As the Koranyi metric and the Carnot-Carathéodory metric are biLipschitz equivalent and \( \delta \) is small enough compared to \( M \), we get that
\[
\inf_{z \in \pi(\Gamma)} \|z - \pi(L)\| > \frac{M_1}{4}.
\]
We have by (12) and Lemma 3.2 that
\[
|\Sigma_{P_L(p_1 \ldots p_N)}^L| < 16\varepsilon^2.
\]
Lemma 3.6. Bsubball projection of

Thus, if we set \( P_L(q_j) - P_L(q_1) \in (jM_1 + \delta, jM_1 - \delta) \).

This is possible because \( \{p_i\} \) is a \( \delta \)-connected set. Then we have that

\[
\Sigma_{\pi_1, p_N}^L = \sum_{i=1}^{N'} \Sigma_{q_{j-1}, q_j}^L,
\]

and so there exists some \( j \) such that \( |\Sigma_{q_{j-1}, q_j}^L| \leq \frac{1}{N} \Sigma_{p_1, p_{N'}}^L < \frac{16}{N} \varepsilon^2 \). Consider the trapezoid \( T_i \) in \( \mathbb{R}^2 \) defined by the points \( \pi(q_{j-1}), \pi((q_{j-1})L), \pi(q_j) \), and \( \pi((q_j)L) \). We have that

\[
|T_i| \geq (M_1 - 2 \delta) \frac{M_1}{4} > \frac{M_1^2}{5}.
\]

Here, we’ve used the fact that \( \delta < \frac{M_1}{10} \). Then

\[
|\Sigma_{q_{j-1}, q_j}| \geq |T_i| - |\Sigma_{q_{j-1}, q_j}^L| \geq \frac{M_1^2}{5} - \frac{16 \varepsilon^2}{N'} \geq \frac{M_1^2}{10}.
\]

Suppose first that \( d(q_{j-1}, q_j) < 10M_1 \). If we set \( B' \subset \mathbb{H} \) to be the ball around \( q_{j-1} \) of radius \( 10M_1 \), then we get by Lemma 3.3 that

\[
\beta(q_{j-1}, q_j)^p \text{diam}(B') \geq \left( \frac{M_1^2/10}{25600M_1^2} \right)^p 10M_1 \geq 10^{-25} M_1.
\]

Here, we’ve used the fact that \( p < 4 \). As \( M_1 > \frac{M}{2} \), we have found a ball \( B' \) that satisfies the second alternative.

Thus, we may suppose that \( d(q_{j-1}, q_j) \geq 10M_1 \). We have now two additional cases: either \( \|\pi(q_{j-1}) - \pi(q_j)\| > 9M_1 \) or \( \|\pi(q_{j-1}) - \pi(q_j)\| \leq 9M_1 \). Consider the first subcase. As \( |P_L(q_{j-1}) - P_L(q_j)| \leq M_1 + 2 \delta < 2M_1 \), we get that \( |P_L(\pi(q_{j-1})) - P_L(\pi(q_j))| > 4M_1 \) where \( L^\perp \) is a line in \( \mathbb{R}^2 \) that is perpendicular to \( L \).

This means that

\[
\max(\|\pi(q_{j-1}) - \pi(L)\|, \|\pi(q_j) - \pi(L)\|) \geq 2M_1,
\]

a contradiction of (13).

Thus, we are now in the subcase when

\[
\|\pi(q_{j-1}) - \pi(q_j)\| \leq 9M_1 < \frac{9}{10} d(q_{j-1}, q_j).
\]

As \( d(q_{j-1}, q_j)^4 = \|\pi(q_{j-1}) - \pi(q_j)\|^4 + NH(q_{j-1}^{-1}q_j)^4 \), we get that

\[
NH(q_{j-1}^{-1}q_j) \geq \frac{4}{5} d(q_{j-1}, q_j).
\]

Thus, if we set \( B' \subset \mathbb{H} \) to be the ball around \( q_{j-1} \) of radius \( 2d(q_{j-1}, q_j) \), we get from Lemma 3.3 that

\[
\beta(q_{j-1}, q_j)^p \text{diam}(B') \geq 25^{-p} 20M_1 \geq 10^{-50} M.
\]

This finishes the proof of the lemma. \( \square \)

Given a ball \( B \subset \mathbb{H} \), we let \( \tilde{\beta}_E(B) \) denote \( \beta_{\pi(\pi(E) \cap B), \mathbb{R}^2}(\pi(B)) \), the regular Jones-\( \beta \)-number \[Jon90\] of the projection of \( E \cap B \) to \( \mathbb{R}^2 \). The following lemma is our angle improvement step, which says that there is either a subball \( B' \) of large diameter with large \( \tilde{\beta}_E(B') \) (i.e. \( \pi(E) \) has a large angle) or there is some other subball \( B'' \) of large diameter with large \( \tilde{\beta}_E(B'') \).

Lemma 3.6. Let \( p < 4, \varepsilon, M, \delta > 0, \) and \( D > 1 \) so that

\[
\varepsilon > M > 10^{10} \varepsilon^2, \quad M > 1000 \delta.
\]
Let $B \subset \mathbb{H}$ be a ball and $L \subset \mathbb{H}$ be a horizontal line. Suppose $E \subset \mathbb{H}$ is a set such that $E \cap B$ is $\delta \text{diam}(B)$-connected in $E \cap DB$ and satisfies the following conditions:

$$
\sup_{x,y \in E \cap B} |P_L(x) - P_L(y)| \geq \frac{1}{4} \text{diam}(B),
$$

(17)

$$
\sup_{z \in E \cap DB} d(z, L) \leq \varepsilon \text{diam}(B),
$$

$$
\sup_{z \in E \cap B} \|\pi(z) - \pi(L)\| = M \text{diam}(B).
$$

Then either there exists a subball $B' \subseteq 2DB$ whose center is a point in $E$ for which if $L'$ is a horizontal line that realizes $\beta_E(B')$ such that

$$
\text{diam}(B') = 30000 \frac{\varepsilon^2}{M} \text{diam}(B),
$$

$$
\bar{\beta}_E(B') \geq 10^{-10} M^2 \frac{\varepsilon^2}{\varepsilon^2},
$$

$$
\sup_{x,y \in E \cap B'} |P_{L'}(x) - P_{L'}(y)| \geq \frac{1}{4} \text{diam}(B'),
$$

or there exists some other subball $B'' \subseteq 2DB$ for which

$$
\text{diam}(B'') \geq M \text{diam}(B),
$$

$$
\beta_E(B'')\text{diam}(B'') \geq 10^{-50} M \text{diam}(B).
$$

Proof. We may suppose that $\text{diam}(B) = 1$ by dilation. Let $a \in E$ be a point such that $\|\pi(a) - \pi(L)\| > \frac{M}{2}$. By (17), there exists some point $b \in E$ so that $|P_L(a) - P_L(b)| \geq \frac{1}{8}$. Let $\{p_j\}_{j=1}^N$ be a sequence in $E \cap DB$ such that $p_1 = a$, $p_N = b$, and $d(p_j, p_{j+1}) < \delta$ for all $j \in \{1, ..., N-1\}$.

We choose an index $i \in \{1, ..., N\}$ such that

$$
\|\pi(p_i) - \pi(L)\| = \sup_{j \in \{1, ..., N\}} \|\pi(p_j) - \pi(L)\| =: M_1 > \frac{M}{2}.
$$

Note that we still have $M_1 \leq \varepsilon$.

If $|P_L(p_i) - P_L(p_N)| \geq |P_L(p_i) - P_L(p_1)|$, then let $\{q_j\}_{j=1}^{N'}$ denote the sequence $\{p_{i+j-1}\}_{j=1}^{i+N+1}$; otherwise, let $\{q_j\}_{j=1}^{N'}$ denote the sequence $\{p_{i-j+1}\}_{j=1}^{i-1}$. That is, $\{q_j\}$ is the subsequence of $\{p_j\}$ that starts from $p_i$ and goes to $p_1$ or $p_N$, whichever is further along $L$.

By truncating a tail end of $\{q_j\}$, we may now suppose that

$$
5000 \frac{\varepsilon^2}{M} \leq |P_L(q_1) - P_L(q_{N'})| < 5000 \frac{\varepsilon^2}{M} + \delta,
$$

$$
|P_L(q_1) - P_L(q_i)| < 5000 \frac{\varepsilon^2}{M}, \quad \forall i \in \{1, ..., N' - 1\}.
$$

Suppose first that there exists some $j \in \{1, ..., N'\}$ so that

$$
d(q_1, q_j) \geq 25000 \frac{\varepsilon^2}{M}.
$$

As $d(q_1, q_j)^4 = \|\pi(q_1) - \pi(q_j)\|^4 + NH(q_1^{-1}q_j)^4$, we get that

$$
NH(q_1^{-1}q_j) \geq \frac{1}{2} d(q_1, q_j).
$$

Then if we set $B''$ to be a ball around $q_1$ of radius $2d(q_1, q_j) \geq 50000 \frac{\varepsilon^2}{M} \geq 50000M$, Lemma 3.3 gives that

$$
\beta_{(q_1, q_j)}(B'')^p \text{diam}(B'') \geq 128^{-p} d(q_1, q_j) \geq 10^{-10} \frac{\varepsilon^2}{M} \geq 10^{-10} M.
$$

This $B''$ would be give the needed $B''$ to finish the proof of the lemma.
Thus, we may suppose that
\[ d(q_1, q_i) < 25000 \frac{\varepsilon^2}{M}, \quad \forall i \in \{1, ..., N\}. \]

Then by applying Lemma 3.3 we get that either there exists an \( i \in \{2, ..., N'\} \) such that
\[ |P_L(q_i) - P_L(q_1)| < \frac{500 \varepsilon^2}{M}, \]
and
\[ \|\pi(q_i) - \pi(L)\| < \frac{M_1}{2}, \]
or there exists a subball \( B'' \subseteq B \) of diameter at least \( M \) for which
\[ \beta_E(B'') \cdot \text{diam}(B'') \geq 10^{-50} M. \]

We may assume the first alternative as the second alternative would give the needed \( B'' \) to finish the proof of the lemma.

Collecting everything together, we now have three points \( q_1, q_i, q_{N'} \) so that
\[
\begin{align*}
\max\{d(q_1, q_i), d(q_1, q_{N'})\} &< 25000 \frac{\varepsilon^2}{M}, \\
\|\pi(q_{N'}) - \pi(L)\| &\leq \|\pi(q_1) - \pi(L)\| = M_1, \quad (18) \\
\|\pi(q_i) - \pi(L)\| &< \frac{M_1}{2}, \quad (19) \\
|P_L(q_i) - P_L(q_1)| &< \frac{500 \varepsilon^2}{M}, \quad (20) \\
5000 \frac{\varepsilon^2}{M} &\leq |P_L(q_1) - P_L(q_{N'})|, \quad (21) \\
M_1 &\geq \frac{M}{2}.
\end{align*}
\]

It is then elementary, although tedious, to show that if \( L' \) is a line in \( \mathbb{R}^2 \) such that
\[ \|\pi(q_1) - L'\| = \|\pi(q_{N'}) - L'\| \leq \frac{M'}{100}, \]
then \( \|\pi(q_i) - L'\| \geq \frac{M'}{100} \). This is because if a line \( L' \) stays too close to \( \pi(q_1) \) and \( \pi(q_{N'}) \), then as (19) is true, the slope of \( L' \) must be too shallow to get close to \( \pi(q_i) \). Details are left to the reader. Thus, if we let \( B' \) be a ball around \( q_1 \) of radius \( 30000 \frac{\varepsilon^2}{M} \), then
\[ \tilde{\beta}_E(B') \geq \frac{M'/100}{30000 \varepsilon^2/M} \geq 10^{-10} \frac{M^2}{\varepsilon^2}. \]

Now suppose \( \beta_E(B') \geq \frac{1}{100} \). Then
\[ \beta_E(B') \cdot \text{diam}(B') = 30000 \beta_E(B') \cdot \frac{\varepsilon^2}{M} \cdot \text{diam}(B) \geq 10^{-4} \frac{\varepsilon^2}{M} \cdot \text{diam}(B) \geq 10^{-4} M \cdot \text{diam}(B). \]

Notice also that \( \text{diam}(B') = \frac{30000 \varepsilon^2}{M} \cdot \text{diam}(B) > M \cdot \text{diam}(B) \). We would then get the needed \( B'' \) to finish the proof of the lemma if we set \( B'' = B' \).

Thus, we may suppose \( \beta_E(B') < \frac{1}{100} \). Note that
\[ \text{diam}(B') = \frac{30000 \varepsilon^2}{M} \cdot \text{diam}(B) < \frac{1}{16} \cdot \text{diam}(B). \]
As $q_1$ was on a $\delta \text{diam}(B)$-connected path from $a$ to $b$ for which $d(a, b) \geq \frac{1}{\pi} \text{diam}(B)$, there exists a sequence $\{r_i\}_{i=1}^N \subset E$ such that

$$r_1 = q_1 = \text{Center}(B'),$$
$$d(r_i, r_{i+1}) < \delta \text{diam}(B),$$
$$d(r_1, r_N) > \frac{1}{2} \text{diam}(B').$$

We also have the estimate that

$$\delta \text{diam}(B) = \delta \frac{\text{diam}(B)}{\text{diam}(B')} \text{diam}(B') = \frac{1}{30000} \delta \frac{M}{\varepsilon^2} \text{diam}(B') \leq 100 \text{diam}(B').$$

Thus, Lemma 3.4 tells us that if $L$ is the horizontal line that realizes $\beta(B')$, then

$$\sup_{x, y, z} |P_L(x) - P_L(y)| \geq \frac{1}{2} \text{diam}(B').$$

We then get the needed $B'$ to finish the proof of the lemma. \qed

The next lemma tells us that if the triangle inequality excess of three spread out points in a ball $B$ is large relative to $\beta(B)$, then $\beta(B)$ must also be large. The $D_2$ term is needed in its application. Below we abuse notation and allow ourselves to write $\mathbb{R}$ for

$$\{(x, 0, 0) \in \mathbb{R} : x \text{ a is real number}\}$$

**Lemma 3.7.** Let $p < 4$, $0 < \alpha_1 < \alpha_2 < 1$, $D > 0$, and $D_2 > 1$. Then there exist $D_0 = D_0(\alpha_1, \alpha_2) > 0$ and $\varepsilon_0 = \varepsilon_0(\alpha_1, \alpha_2, p, D) \in (0, 1)$ so that the following property holds. Let $B \subset \mathbb{H}$ a ball and $E \subset \mathbb{H}$ be a subset so that

$$\sup_{z \in E \cap D_2 B} d(z, \mathbb{R}) = \varepsilon \text{diam}(B),$$

for some $\varepsilon < \varepsilon_0$. If $p_1, p_2, p_3 \in E \cap B$ so that $\alpha_1 \text{diam}(B) \leq d(p_1, p_i) \leq \alpha_2 \text{diam}(B)$ and

$$d(p_1, p_2) + d(p_2, p_3) - d(p_1, p_3) = \eta \text{diam}(B) \geq D \varepsilon^p \text{diam}(B),$$

then one of the $y$ coordinates of $p_i$ has absolute value at least $\frac{1}{150} \eta^{1/2} \text{diam}(B)$.

**Proof.** Let $D_3$ denote the minimal number such that

$$((x + y)^2 + z)^{1/4} \leq x^{1/2} + D_3(y + z),$$

when $x, y, z \in \mathbb{R}^+$ satisfy the bounds $\frac{\alpha_1}{\alpha_2} \leq x \leq \alpha_2$, $0 \leq y \leq 1$, and $0 \leq z \leq 1$. That such a $D_3$ exists follows from repeated use of Taylor’s approximation and clearly depends only on $\alpha_1$ and $\alpha_2$. Then we set $D_0 = \max\{150, 150D_3^{-1/2}\}$.

Suppose the lemma is false, that is, we have $[42]$ but the $y$ coordinates for all the $p_i$ have absolute value less than $\frac{1}{150} \eta^{1/2} \text{diam}(B)$. We can dilate the setting so that $\text{diam}(B) = 1$ and translate so that the $x$ coordinate of $p_2$ is 0. We label the points $p_i = (x_i, y_i, z_i)$ so that $x_2 = 0$. Then we have that

$$d(p_1, p_2) + d(p_2, p_3) - d(p_1, p_3) \leq \left((x_1^2 + (y_1 - y_2)^2 + (z_1 - z_2 + 2x_1y_2)^2)^{1/4} + ((x_1^2 + (y_2 - y_3)^2 + (z_2 - z_3 - 2x_2y_3)^2)^{1/4} - |x_1 - x_3|.

As we are supposing that $|y_i| < \frac{1}{150} \eta^{1/2}$, we must have that $|y_1 - y_2| < \frac{2}{150} \eta^{1/2}$.

We also claim that

$$|\Sigma_{p_1, p_2}| = \frac{1}{4} |z_1 - z_2 + 2x_1y_2| < \frac{2}{D_0} \eta^{1/2}.$$
\[ \pi((p_2)_L) \text{ is no more than } \frac{1}{\eta^2} \eta^{1/2}. \] Thus, we would have that
\[ |\Sigma^L_{p_1, p_2}| \leq |\Sigma_{p_1, p_2}| - T > \frac{1}{D_0} \eta^{1/2} \geq \frac{D^{1/2}}{D_0} \varepsilon^{p/2}. \] As Lemma 3.2 then says that
\[ \max\{d(p_1, L), d(p_2, L)\} > \frac{D^{1/4}}{2D_0^{1/2}} \varepsilon^{p/4}. \]
As \( p < 4 \), we see that we would contradict the fact that \( \beta_E(B) = \varepsilon \) if \( \varepsilon \leq \varepsilon_0 \) for some \( \varepsilon_0 \) that we can set to depend only on \( D_0, D, \) and \( p. \)
Finally, as \( \eta \leq 2 \), we have that both \( |y_1 - y_2| < \frac{2}{\eta^2} \eta^{1/2} \leq 1 \) and \( |z_1 - z_2 + 2x_1y_2| < \frac{8}{\eta^2} \eta^{1/2} \leq 1 \). Thus, we have by definition of \( D_3 \) that
\[ ((x_1^2 + (y_1 - y_2)^2)^2 + (z_1 - z_2 + 2x_1y_2)^2)^{1/4} \leq |x_1| + D_3 ((|y_1 - y_2|^2 + |z_1 - z_2 + 2x_1y_2|^2). \] The same thing holds with \( d(p_2, p_3) \) and so we get by our choice of \( D_0 \) that
\[ d(p_1, p_2) + d(p_2, p_3) - d(p_1, p_3) \leq D_3 ((|y_1 - y_2|^2 + |z_1 - z_2 + 2x_1y_2|^2 + (y_2 - y_3)^2 + (z_2 - z_3 - 2x_2y_3)^2) < \eta, \] a contradiction. \( \square \)

4. Main proposition

**Remark 1.** In Proposition 4.1 below, we always have \( q \in [2, p) \) or
\[ d(p_1, p_2) + d(p_2, p_3) - d(p_1, p_3) \leq D_{FPP} \beta_\beta(B)^2 \text{diam}(B) \]
The existence of the constant \( D_{FPP} < \infty \) follows from Theorem 2.14 of [FPP07] (see equation (2.51) there).

**Proposition 4.1.** Let \( p < 4, 0 < \alpha_1 < \alpha_2 < 1 \) and \( D_7 > 1 \) be given. Let \( D = D_{FPP}(\alpha_1/D_7, \alpha_2/D_7) > 0 \) be the constant from Remark 1. There exists constants \( D_1 = D_1(\alpha_1, \alpha_2, p, D_7) > 0 \) and \( \varepsilon_1(\alpha_1, \alpha_2, p, D_7) \in (0, 1) \) so that the following holds. Let \( B \subset \mathbb{H} \) be a ball and suppose \( \varepsilon \subseteq \mathbb{H} \) is such that
\[ \beta_E(D_1B) = \frac{\varepsilon}{D_7} \leq \varepsilon_1(\alpha_1, \alpha_2, p). \]
If \( p_1, p_2, p_3 \in E \cap B \) so that \( \alpha_1 \text{diam}(B) \leq d(p_1, p_2) \leq \alpha_2 \text{diam}(B), \)
\[ d(p_1, p_2) + d(p_2, p_3) - d(p_1, p_3) \leq D_\varepsilon^q \text{diam}(B) > D_\varepsilon^p \text{diam}(B), \] for some \( q < p, \) and for every subball \( B' \subseteq 4D_7B \) of diameter at least \( \frac{1}{D_1} \varepsilon^{q/2} \text{diam}(B) \), \( E \cap B' \) is \( \frac{1}{D_1} \varepsilon^{q/2} \text{diam}(B) \)-connected inside \( E \cap D_7B' \), then there exists a subball \( B'' \subseteq 4D_7B \) of diameter
\[ \text{diam}(B'') \geq \frac{1}{D_1} \varepsilon^{q/2} \text{diam}(B) \]
so that
\[ d(p_1, p_2) + d(p_2, p_3) - d(p_1, p_3) \leq D_3 \beta_E(D_7B'')^p \text{diam}(D_7B''). \]

**Proof.** We first choose \( \varepsilon_1 \) small enough so that \( \varepsilon_1 \leq \varepsilon_0(\alpha_1, \alpha_2, p, D) \) where \( \varepsilon_0 \) is from Lemma 3.7. By rotation, we may assume that the horizontal line realizing \( \beta_E(D_7B) \) projects to the x-axis. Then as \( \beta_E(D_7B) = \frac{\varepsilon}{D_7}, \) Lemma 3.7 says there exists a constant \( D_0 \) so that
\[ M := \frac{1}{\text{diam}(B)} \sup_{z \in B} \|\pi(z) - \pi(L)\| \geq \frac{D^{1/2}}{D_0} \varepsilon^{q/2}. \]
As \( 2 \leq q < 4, \) if we set \( \varepsilon_1 \) smaller than some constant depending only on \( D \) and \( D_0, \) we then get that \( \varepsilon > M > 10^{10} \varepsilon^2. \) Thus, an application of Lemma 3.6 gives us either a ball \( B' \subset 2D_7B \) for which
\[ \text{diam}(B') = 30000 \frac{\varepsilon^2}{M} \text{diam}(B), \]
\[ \beta_E(B') \geq 10^{-10} \frac{M^2}{\varepsilon^2}, \]
or some other ball $B'' \subset 2D_T B$

\[
\text{diam}(B'') \geq M \text{diam}(B), \\
\beta_E(B'')^p \text{diam}(B'') \geq 10^{-50} M \text{diam}(B).
\]

If we have the latter case, then as $M \geq \frac{\varepsilon}{\varepsilon^{1/2}} \geq \frac{\varepsilon^{3/2}}{\varepsilon^2}$, we get that $B''$ is our needed ball if we specify $D_1$ large enough. Thus, we may suppose that we have a ball that satisfies the conditions in the first case. Let us denote this ball $B_1$.

We let $L_1$ denote the horizontal line that realizes the infimum of $\beta_E(D_T B_1)$. Then

\[
M_1 := \frac{1}{\text{diam}(B_1)} \sup_{z \in E \cap B_1} \|\pi(z) - \pi(L_1)\| \geq \beta_E(B_1).
\]

We then let $\alpha_1 \in [0, 1]$ be such that

\[
\beta_E(D_T B_1) = \frac{M_1^{\alpha_1}}{D_T}.
\]

Suppose $\alpha_1 \leq \frac{2}{p}$. Then as $\tilde{\beta}_E(B_1) \leq 1$, we have that

\[
\beta_E(D_T B_1)^p \text{diam}(D_T B_1) = \frac{M_1^{\alpha_1}}{D_T^{p-1}} \text{diam}(B_1) \geq \frac{1}{D_T^{p-1}} \tilde{\beta}_E(B_1)^2 \text{diam}(B_1) \geq \frac{1}{D_T^{p-1}} 10^{-20} \frac{M_1^3}{\varepsilon^2} \text{diam}(B)
\]

\[
\geq \frac{D^{3/2}}{10^{20} D_T^{p-1} D_0^2} \varepsilon^2 D - \frac{20}{20 D_T^{p-1} D_0^2} \varepsilon^2 \text{diam}(B).
\]

In the last inequality, we used the fact that $q < p < 4$. This would give that $D_T B_1$ is a ball that would satisfy the claim of the proposition for sufficiently large $D_1$. Thus, we may suppose that $\alpha_1 > \frac{2}{p}$.

Now suppose $M_1 \leq 10^{10} M_1^{2\alpha_1}$, that is,

\[
M_1 \geq 10^{-10(1-2\alpha_1)}.
\]

As $p$ is some fixed number strictly less than 4 and $\alpha_1 > \frac{2}{p}$, we get that there exists some $C > 0$ depending only on $p$ so that $M_1 > C$. Thus,

\[
\beta_E(D_T B_1)^p \text{diam}(D_T B_1) = \frac{M_1^{\alpha_1}}{D_T^{p-1} D_0^3} 30000 \varepsilon^2 \text{diam}(B) \geq 30000 \frac{C^{\alpha_1}}{D_T^{p-1} D_0^3} M \text{diam}(B)
\]

\[
> 30000 C^{\alpha_1} D_1^{p-1}\varepsilon^2 \text{diam}(B) \geq 30000 C^{\alpha_1} D_1^{p-1}\varepsilon^2 \text{diam}(B).
\]

Again, we would have that $B_1$ is a ball that would satisfy the claim of the proposition for sufficiently large $D_1$. Thus, we may suppose $M_1 > 10^{10} M_1^{2\alpha_1}$.

We now have the following information about $L_1$ and $B_1$:

\[
M_1^{\alpha_1} > M_1 > 10^{10} M_1^{2\alpha_1},
\]

\[
\sup_{x, y \in E \cap B_1} |P_{L_1}(x) - P_{L_1}(y)| \geq \frac{1}{4} \text{diam}(B_1),
\]

\[
\sup_{z \in E \cap D_T B_2} d(z, L_1) = M_1^{\alpha_1} \text{diam}(B_1),
\]

\[
\sup_{z \in E \cap B_1} \|\pi(z) - \pi(L_1)\| = M_1 \text{diam}(B_1),
\]

\[
\text{diam}(B_1) = 30000 \frac{\varepsilon^2}{M} \text{diam}(B).
\]

Suppose that we have a sequence of subballs $B_1, ..., B_n$ with the following properties. Each $B_j$ is contained in $2D_T B_{j-1}$. If $L_k$ is the horizontal line realizing $\beta_E(D_T B_k)$ then

\[
\sup_{x, y \in E \cap B_k} |P_{L_k}(x) - P_{L_k}(y)| \geq \frac{1}{4} \text{diam}(B_k).
\]
If
\[ M_k := \frac{1}{\text{diam}(B_1)} \sup_{z \in E \cap B_k} \|\pi(z) - \pi(L_k)\| \geq \breve{\beta}_E(B_k), \]
then
\[ \beta_{E}(D_7 B_k) = \frac{M_k^{\alpha_k}}{D_7}, \]
for some \( \alpha_k \in (2/p, 1] \). Furthermore we have the estimates
\[ M_k^{\alpha_k} > M_k > 10^{10} M_k^{2\alpha_k}, \]
\[ M_k \geq 10^{-10k} \left( \frac{M^2}{\varepsilon^2} \right)^{2^{k-1} - 1} \left( 1 - \alpha_1 \cdots (1 - \alpha_{k-1}) \right), \]
\[ \text{diam}(B_k) = 30000^k \left( \frac{M^2}{\varepsilon^2} \right)^{1 - 2^{k-1} - (1 - \alpha_1) \cdots (1 - \alpha_{k-1})} \frac{\varepsilon^2}{M} \text{diam}(B). \]

Here, the term \( 2^{k-1} - 1 - \alpha_1 \cdots (1 - \alpha_{k-1}) \) is understood to be 1 if \( k = 1 \). Then
\[ \frac{1}{D_1} \varepsilon^{q/2} \text{diam}(B) = \frac{1}{D_1} \varepsilon^{q/2} \text{diam}(B) \frac{\text{diam}(B_m)}{\text{diam}(B)} \]
\[ = \frac{1}{30000^m D_1} M \frac{\varepsilon^{q/2}}{\varepsilon^2} \left( \frac{M^2}{\varepsilon^2} \right)^{1 - 2^{m-1} - (1 - \alpha_1) \cdots (1 - \alpha_{m-1})} \text{diam}(B_m) \leq \frac{1}{100} M_m \text{diam}(B_m), \]
where in the last inequality we used the fact we can set \( D_1 \) large enough and that
\[ M_m \geq 10^{-10m} \left( \frac{M^2}{\varepsilon^2} \right)^{1 - 2^{m-1} - (1 - \alpha_1) \cdots (1 - \alpha_{m-1})} \left( \frac{M^2}{\varepsilon^2} \right)^{1 - 2^{m-1} - (1 - \alpha_1) \cdots (1 - \alpha_{m-1})} \frac{\varepsilon^2}{M} \text{diam}(B). \]

Thus, we can apply Lemma 3.6 to \( B_m \) to give us either a ball \( B' \subseteq 2D_7 B_m \) so that
\[ \text{diam}(B') = 30000^m \frac{M^{2\alpha_m}}{M_m} \text{diam}(B_m) \geq 30000^{m+1} \left( \frac{M^2}{\varepsilon^2} \right)^{1 - 2^{m-1} - (1 - \alpha_1) \cdots (1 - \alpha_{m-1})} \frac{\varepsilon^2}{M} \text{diam}(B), \]
\[ \breve{\beta}_E(B') \geq 10^{-10} M_m^{2(1 - \alpha_m)} \geq 10^{-10(m+1)} \left( \frac{M^2}{\varepsilon^2} \right)^{2^m(1 - \alpha_1) \cdots (1 - \alpha_m)}, \]
or some other ball \( B'' \subseteq 2D_7 B_m \)
\[ \text{diam}(B'') \geq M_m \text{diam}(B_m) \geq 10^{-10k} \left( \frac{M^2}{\varepsilon^2} \right) \frac{\varepsilon^2}{M} \text{diam}(B) \geq 10^{-10k} M \text{diam}(B), \]
\[ \beta_{E}(B'')^p \text{diam}(B'') \geq 10^{-50} M_m \text{diam}(B_m) \geq 10^{-50-50} M \text{diam}(B). \]

If we have the latter case, then as \( M \geq \frac{D_1^{1/2} \varepsilon^{q/2}}{D_0} \geq \frac{D_1^{1/2} \varepsilon^q}{D_0} \), we get that \( B'' \) is our needed ball if we specify that \( D_1 \) is large enough. Thus, we can inductively construct these \( B_k \).

Like before, we let \( L_{m+1} \) denote the horizontal line that realizes the infimum of \( \beta_{E}(D_7 B_{m+1}) \). Then
\[ M_{m+1} := \frac{1}{\text{diam}(B_{m+1})} \sup_{z \in E \cap B_{m+1}} \|\pi(z) - \pi(L_{m+1})\| \geq \breve{\beta}_E(B_{m+1}). \]

We then let \( \alpha_{m+1} \in [0, 1] \) be such that
\[ \beta_{E}(D_7 B_{m+1}) = \frac{M_{m+1}^{\alpha_{m+1}}}{D_7}. \]

As before, we may suppose that \( \alpha_{m+1} > \frac{2}{p} \) and that \( M_{m+1} > 10^{10} M_m^{2\alpha_{m+1}} \) as otherwise we would be done if we specify that \( D_1 \) is large enough. Thus, we have exhibited a subball \( B_{m+1} \) that allows us to apply Lemma 3.6 again.

Continuing inductively, we get that for each \( k > 0 \), if we specify \( D_1 \) large enough, then we can find subballs satisfying (28) and (29) (if such a ball does not exist, then sometime during the induction, we would have
found a ball that satisfies the conclusion of the proposition). Note that \( D_1 \) for now depends on the \( k \) that we specify.

Let \( m \) be the smallest integer such that \( 2^{m-1} \left( 1 - \frac{2}{p} \right)^{m-1} \leq \frac{1}{2} \). Such a number exists as \( p < 4 \) and so \( 1 - \frac{2}{p} < \frac{1}{2} \). We then see that \( m \) is a constant depending only on \( p \). As \( \alpha_m p > 2 \), we get that

\[
\beta_E (D_7 B_m)^p \text{diam}(D_7 B_m) \geq \frac{M^2_{m}}{D_{7}^{p-1}} \text{diam}(B_m) \geq \frac{1}{10^{10m} D_7^{p-1}} \left( \frac{M^2}{\varepsilon^2} \right)^{2^{m-1} \left( 1 - \alpha_1 \right) \cdots \left( 1 - \alpha_{m-1} \right)} M \text{diam}(B) = (*).
\]

Note that

\[
2^{m-1} \left( 1 - \alpha_1 \right) \cdots \left( 1 - \alpha_{m-1} \right) \leq 2^{m-1} \left( 1 - \frac{2}{p} \right)^{m-1} \leq \frac{1}{2},
\]

where we again used the fact that \( \alpha_k > \frac{2}{p} \). As \( M \leq \varepsilon \), we get that

\[
(*) \geq \frac{1}{10^{10m} D_7^{p-1}} \varepsilon \text{diam}(B) \geq \frac{1}{10^{10m} D_7^{p-1}} \frac{D}{D_7} \varepsilon^{q-1} \text{diam}(B) \geq \frac{1}{10^{10m} D_7^{p-1}} \frac{D}{D_7} \varepsilon^{q} \text{diam}(B).
\]

As \( m \) is some constant depending only on \( p \), so is the needed \( D_1 \) and so we get that by choosing \( D_1 \) even larger

\[
d(p_1, p_2) + d(p_2, p_3) - d(p_1, p_3) \leq D_1 \beta_E (D_7 B_m)^p \text{diam}(D_7 B_m).
\]

\[ \square \]

5. The Construction and its Length

Let \( E \subset \mathbb{H} \) be a set and \( r \in (2, 4) \). We would like to construct \( \Gamma \supset E \), a continuum, such that we control the length of \( \Gamma \) by

\[
\text{diam}(E) + \int_0^{\int_0} \beta_E (B(x, r))^q \frac{dt}{t^3} dH^4(x), \tag{30}
\]

which we are assuming is bounded. To this end, we will use the algorithm from [Jon90]. This had been done before in [FFP07], where the estimates established (30) for \( r = 2 \). We will follow the same notation and refer to the detailed work done in section 3 of [FFP07]. In fact, with some appropriate choices, we will only need to modify the estimates for one of their cases in a non-trivial manner. In other words, the construction in [FFP07] works as is (but see Remark 2). However, the estimate (30) for \( r = 2 \) obtained in [FFP07] can be improved to yield (30) for any \( r \in (2, 4) \), and that is what we do below. We let

\[
p = \frac{r + 4}{2} < 4.
\]

Remark 2. in [FFP07] the Carnot-Carathéodory metric was used for the definitions and construction. We will use a different (equivalent) metric, namely the Koranyi metric. When we say we use the [FFP07] construction, we mean we use the same algorithm, but with respect to the Koranyi metric, i.e. all nets, balls etc. are with respect to this metric.

Remark 3. We will assume that the reader is very familiar with [FFP07] and has it on hand. In order to avoid confusion, in this section we use the exact same notation as in [FFP07]. We allow ourselves to reduce the value of the constant \( \varepsilon_0 > 0 \) and increase the value of the constant \( C_1 > 1 \). We will assume in particular that \( \varepsilon_0 \leq \varepsilon_1 \) of Proposition 4.1

Remark 4. We describe the dependency of constants below. All of them are allowed to depend on \( r \). When we will be invoking Proposition 4.1 we will always do so with the constant

\[
D_7 = 2C_1.
\]

\( C_1 \) needs to be large enough. The constant \( D_1 \) depends on \( r \), \( C_1 \). The constant \( D_{10} \) depends on \( C_1, D_7 \) and \( r \). The constant \( R \) depends on \( C_1, D_1 \) and \( r \). The constant \( \varepsilon_0 \) depends on \( C_1, R \) and \( r \). The constant \( C_r \)
depends on $C_1$ and $r$. The constant $\varepsilon_0$ is the only one that needs to be sufficiently small, the rest of the dependencies are lower bounds.

The construction in [FFP07] is inductive, and there are 3 hypotheses which hold at every step of the process: (P1), (P2),(P3). We will add two more (P4) and (P5), and claim that they hold as well.

(P4): For any $P \in \Delta_k$, we have that $B(P,C_12^{-k}) \cap \Delta_k$ is connected via $\Gamma_k \cap B(P,C_12^{-k})$.
(P5): If $\beta_{\tilde{H}}(B(P,C_12^{-k})) < \varepsilon_0$ and $I \in \Gamma_k \cap B(P,C_12^{-k})$ is an interval, then $I$ is in the $2^{-k}C_1\varepsilon_0$ neighborhood of $\Gamma_{k+1}$. Furthermore, there is a map $I \to I_1$ which take the interval $I$ to a polygonal curve $I_1 \subset \Gamma_{k+1}$. This is the only way in which an interval $I$ may be deleted.

Suppose without loss of generality that $E$ is closed. We now proceed precisely as in the construction of [FFP07], however we will replace the estimates of Case B1 with Case B1', specifically, we will improve on equation (3.4), p. 465 of [FFP07] via improving on the estimates for the quantities $S_1, S_2$. Case B2(i).2 will follow similar changes. Let $B = B(P,C_12^{-j}).$

Case B1': Since $\beta_{\tilde{H}}(B) < \varepsilon_0$ (which we may, as we are not in Case A), there exists an order on $\Delta_j \cap B(P,C_12^{-j}) = [P_1, ..., P_n]$. We separate into two case, based on the validity of the assumptions for Proposition 4.1.

Case B1'(i): For each triple of the form $[p_1,p_2,p_3] = [P_1, P_2, P_3]$ where $1 \leq i_1 < i_2 < i_3 \leq n$ one of two things happens: either we may apply Proposition 4.1 or assumption (23) of Proposition 4.1 fails for all $q < p$.

Suppose Proposition 4.1 is applicable to $B$ and the triple of points $P_1, P_2, P_3$. Then it guaranties a ball $B'' = B''[P_1, P_2, P_3]$. There is a ball which we denote by $F_1(B, i_1, i_2, i_3)$ with center $z \in \Delta_k$ and radius $C_12^{-k}$ for some $k \in \mathbb{N}$, such that $B'' \subset F_1(B, i_1, i_2, i_3) \subset 10B''$. By multiplying the constant $D_1$ by a factor, we may assume without loss of generality that the conclusion of Proposition 4.1 holds for $F_1(B, i_1, i_2, i_3)$. Using this notation we proceed. As in [FFP07] and using Proposition 4.1 as well as the fact that the numbers of tuples $1 \leq i_1 < i_2 < i_3 \leq n$ is bounded independently of $B$ (or $E$) we have

$$S_1 \leq C \left( \beta_{\tilde{H}}(B)^p \text{diam}(B) + \sum_{1 \leq i_1 < i_2 < i_3 \leq n} D_1 \beta_{\tilde{H}}(D_7 F_1(B, i_1, i_2, i_3))^p \text{diam}(D_7 F_1(B, i_1, i_2, i_3)) \right),$$

where

$$(*) \quad \text{Proposition 4.1 is applicable.}$$

Because of the first term, this inequality holds even if assumption (23) fails for all $q < p$. We have that when $F_1(B, i_1, i_2, i_3)$ is defined, it satisfies (for $q \in [2,4]$) depending on $[P_1, P_2, P_3])$

$$\text{diam}(F_1(B, i_1, i_2, i_3)) \geq \frac{1}{D_1} \beta_{\tilde{H}}(B)^{q/2} \text{diam}(B).$$

which may be weakened to

$$\text{diam}(F_1(B, i_1, i_2, i_3)) \geq \frac{1}{D_1} \beta_{\tilde{H}}(B)^{p/2} \text{diam}(B).$$

Similarly for $S_2$. This gives an improvement over equation (3.4) in [FFP07] (changing the value of $C$ to incorporate $D_1$):

$$l(\Gamma_j) - l(\Gamma_{j-1}) \leq C \left( \beta_{\tilde{H}}(B)^p \text{diam}(B) + \sum_{1 \leq i_1 < i_2 < i_3 \leq n} \beta_{\tilde{H}}(D_7 F_1(B, i_1, i_2, i_3))^p \text{diam}(D_7 F_1(B, i_1, i_2, i_3)) \right).$$
Let denote by $B_{B_1'}$, the collection of all balls which fall into Case B1'(i) and satisfy (*). The function $B \to F_1(B,\cdot)$ is at most $C \log(1/\beta_3(B))$ to 1. Thus
\[
\sum_{B \in B_{B_1'}} \beta_3(D_7F_1(B,i_1,i_2,i_3))^p \text{diam}(D_7F_1(B,i_1,i_2,i_3))
\]
\[
\leq \sum_{t=0}^{\infty} \sum_{B \in B_{B_1'}} \beta_3(D_7F_1(B,i_1,i_2,i_3))^p \text{diam}(D_7F_1(B,i_1,i_2,i_3))
\]
\[
\leq \sum_{t=0}^{\infty} 2^{-(t-1)(p-r)} \sum_{B \in B_{B_1'}} \beta_3(D_7F_1(B,i_1,i_2,i_3))^p \text{diam}(D_7F_1(B,i_1,i_2,i_3))
\]
\[
\leq \sum_{t=0}^{\infty} (2^{-(t-1)(p-r)} \sum_{j \in \mathbb{N}} \sum_{P \in \Delta_j} \beta_3(P,D_10^{-j})^p 2^{-j}
\]
\[
\leq C_r \sum_{j \in \mathbb{N}} \sum_{P \in \Delta_j} \beta_3(P,D_10^{-j})^p 2^{-j}
\]
where $C_r = \sum_{t=0}^{\infty} t2^{-(t-1)(p-r)} < \infty$ as $p = \frac{q}{q+4}$. We summarize this as
\[
\sum_{B \in B_{B_1'}} \beta_3(D_7F_1(B,i_1,i_2,i_3))^p \text{diam}(D_7F_1(B,i_1,i_2,i_3)) \leq C_r \sum_{j \in \mathbb{N}} \sum_{P \in \Delta_j} \beta_3(P,D_10^{-j})^p 2^{-j}.
\]

**Case B1'(ii):** In this case there is at least one (ordered) triple $[P_{i_1}, P_{i_2}, P_{i_3}]$, $1 \leq i_1 < i_2 < i_3 \leq n$, where we cannot apply Proposition 4.1 and assumption 2.3 holds for some $q \in [2,p)$. Let us fix such an instance $(i_1,i_2,i_3)$. Since we are not in Case A, we conclude the existence of a ball $F_2(B) = B' \subset 4D_7B$ of diameter $\text{diam}(F_2(B)) \geq \frac{1}{2\alpha} \varepsilon^{q/2} \text{diam}(B)$ which has $E \cap F_2(B)$ is not $\frac{1}{10} \varepsilon^{q/2} \text{diam}(B)$-connected inside $E \cap D_7F_2(B)$, where $\varepsilon^q \text{diam}(B) = \beta_3(B)^q \text{diam}(B) = \frac{1}{2\alpha} \varepsilon^{q/2} \text{diam}(B) - d(P_{i_1}, P_{i_2}) + d(P_{i_2}, P_{i_3}) - d(P_{i_1}, P_{i_3})$. As stated in Remark 4, $D_7 = 2C_1$.

Let
\[
\alpha \in \left[\frac{1}{D_1} \varepsilon^{q/2} \text{diam}(B), 4D_7 \text{diam}(B)\right]
\]
be the largest number of the form $2^{-k}$ such that $E \cap F_2(B)$ is not $\alpha$-connected inside $2C_1F_2(B)$, but is $2\alpha$-connected inside $2C_1F_2(B)$, with $F_2(B) \subset 4D_7B$ and $\text{diam}(F_2(B)) \geq \alpha$. Let $x, y \in E \cap F_2(B)$ be two points of distance $(\alpha, 2\alpha]$ which witness to this (discrete) non-connectedness, and minimize $d(x,y)$. Let $k$ be such that $2^{-k} = \alpha/128$, and let $x', y' \in \Delta_k \cap \frac{10}{101} F_2(B)$ be minimize distance to $x, y$ respectively. If $C_1 > 2^{10}$, then $B(x', C_12^{-k}) \supset B(x', 3\alpha) \supset y'$, and thus (from (P4)), the points $x', y'$ are connected via $\Gamma_k \cap B(x', C_12^{-k})$ with a polygon $P_{x,y}$ of edges $\geq 2^{-k}$.

Since segments are only modified in cases other than Case A, we have by (P5) that $P_{x,y}$ is in the $2\alpha C_1^{-k}$ neighborhood of the limit curve $\Gamma$, and furthermore, that there is an arc $\Gamma_{x,y} \subset \Gamma$ which contains $P_{x,y}$ in its $2\alpha C_1^{-k}$ neighborhood. If we take $\varepsilon_0$ small enough so that $C_1^2 \varepsilon_0 < 1/100$, then $x, y$ are in the $\alpha/10$ neighborhood of $\Gamma_{x,y}$. Furthermore, $\Gamma_{x,y} \subset B(x', C_12^{-k}) \subset C_1F_2(B)$. Recall that $x, y$ are not $\alpha$-connected inside $2C_1F_2(B)$ and that $\text{rad}(F_2(B)) \geq \alpha/2$, which gives us the following lemma.

**Lemma 5.1.** There is a connected set $\Gamma_B \subset \Gamma_{x,y}$ such that
\[
\Gamma_B \subset \Gamma
\]
\[
\frac{1}{10} \alpha \leq \text{diam}(\Gamma_B) \leq \frac{2}{10} \alpha
\]
\[
\frac{1}{10} \alpha \leq \text{d}(\Gamma_B, E) \leq \alpha
\]
Proof. We proceed by contradiction. Suppose that any candidate connected set $G$ satisfying (32) and (33) fails $\frac{1}{10} \alpha \leq d(G, E)$. This means that $x'$ and $y'$ are $\frac{1}{10} \alpha$-connected in $E \cap (C_1 + 1) F_2(B)$, which is contradiction since $x, y$ are not $\alpha$-connected inside $2C_1 F_2(B)$ and $d(x, x') d(y, y') < \alpha / 128$. Thus we have a connected $G$ satisfying (32) and (33) and $\frac{1}{10} \alpha \leq d(G, E)$. The connectedness of $\Gamma_{x, y}$ and the fact that $x' \in E$ then implies that there is also a $G$ satisfying the RHS of (34) in addition to the above properties.

Let $R$ be a large constant to be chosen, and recall that $p = \frac{t+4}{2}$, i.e. $\frac{4 - t}{8} + p/2 < 2$. Suppose also that $\varepsilon_0$ is small enough so that $\varepsilon_0^{\frac{4 - t}{8} + p/2} > R \varepsilon_0^2$. Since we have $q < p < 4$ and $\beta_\Omega(B) < \varepsilon_0$, this improves (33) above to

$$H^1(\Gamma_B) \beta_\Omega(B) \varepsilon_0^{4 - t} \geq R \frac{1}{2D_1} \beta_\Omega(B) 2 \varepsilon_0.$$

which means that the cost of the algorithm in this case is dominated by $H^1(\Gamma_B) \beta_\Omega(B) \varepsilon_0^{4 - t}$.

Lemma 5.2. Let $x_0 \in \Gamma$ and $t \in \mathbb{N}$. Then

$$\# \{ B = B(z, C_1 2^{-j}) : j \in \mathbb{N}; z \in \Delta_j; \Gamma_B \ni x_0; \beta_\Omega(B) \in [2^{-t}, 2^{-t+1}] \} < Ct. \quad (36)$$

Equation (36) will be used in conjunction with (35) above later on.

Proof. First note that since $\mathbb{H}$ is doubling, only a fixed number of balls of any fixed scale may intersect at a point. This, together with the fact that

$$\Gamma_B \subset \Gamma_{x, y} \subset 2D_7B$$

gives us a uniform bound for the number of balls on the left hand side of (36) of a single scale. We now address the question of how many scales can come into play.

The answer will follow from (33), (34) above. Let $B_1 = B(z_1, C_1 2^{-t_1})$ be a ball, and suppose $x_0 \in \Gamma_{B_1}$. Now we have that if $B$ is a ball on the left hand side of (36), then

$$\operatorname{diam}(B) \leq 10D_1 2^{2t} \operatorname{diam}(\Gamma_B, E) \leq 10D_1 2^{2t} (\operatorname{diam}(\Gamma_{B_1}) + \operatorname{diam}(\Gamma_{B_1}) + \operatorname{diam} \Gamma_{B_1}, E)) \leq 10D_1 2^{2t} (8D_7 \operatorname{diam}(B_1)) = C2^{2t} \operatorname{diam}(B_1) \quad (37)$$

and in the same way, $\operatorname{diam}(B_1) \leq C2^{2t} \operatorname{diam}(B)$. Thus, only $O(t)$ of scales need to be considered, giving the lemma.

Let denote by $B_{B_1}$ the collection of all balls which fall into Case B1’(ii). We sum as follows, using (35) and Lemma 5.2

$$\sum_{B \in B_{B_1}} \beta_\Omega(B)^2 \operatorname{diam}(B) \leq \sum_{B \in B_{B_1}} \frac{2D_1}{R} H^1(\Gamma_B) \beta_\Omega(B) \varepsilon_0^{4 - t} \leq \sum_{t=0}^{\infty} \sum_{\beta_\Omega(B) \in [2^{-t}, 2^{-t+1}]} \frac{4D_1}{R} H^1(\Gamma_B)^{2 - t} \leq \frac{4D_1}{R} \sum_{t=0}^{\infty} t H^1(\Gamma)^{2 - t} \leq \frac{4D_1}{R} C(r) H^1(\Gamma) \quad (38)$$

Finally, we note that increasing $R$ (which forces us to decrease $\varepsilon_0$ accordingly), reduces $\frac{4D_1}{R} C(r)$ to being arbitrarily close to 0.

Case B2(i).2 appeals to the estimates in Case B1. The estimates for Case B1’ work to give Case B2(i).2’.

The rest of the cases follow with the same estimates as those in Section 3 of [FFP07]. This allows us to improve the estimate at the top of page 468 of [FFP07] to give (30) (increasing their value of $C_1$, and allowing $C$ to change form line to line). Specifically, we use equations (31), (38) to get:
\[ H^1(\Gamma) \leq C \operatorname{diam}(E) + C \sum_{j \in \mathbb{N}} \sum_{P \in \Delta_j} \beta_{\mathbb{H}}(P, C_1 2^{-j})^p 2^{-j} + \frac{1}{10^6} H^1(\Gamma) + \frac{1}{10^3} H^1(\Gamma) \]
\[ + C \sum_{j \in \mathbb{N}} \sum_{P \in \Delta_j} \beta_{\mathbb{H}}(D_7 F_1(B(P, C_1 2^{-j})))^p 2^{-j} + \frac{4D_1}{R} C_r H^1(\Gamma) \]
\[ \leq C \operatorname{diam}(E) + C_r \sum_{j \in \mathbb{N}} \sum_{P \in \Delta_j} \beta_{\mathbb{H}}(P, D_{10} 2^{-j})^r 2^{-j} + \frac{1}{10} H^1(\Gamma) \]

where we made \( R \) and \( D_{10} \) large enough. Note \( R \) is independent of \( C \) above, which is important since \( C \) above grows as \( \varepsilon_0 \to 0 \), and \( \varepsilon_0 \) depends on \( R \). Hence
\[ H^1(\Gamma) \leq C \operatorname{diam}(E) + C_r \sum_{j \in \mathbb{N}} \sum_{P \in \Delta_j} \beta_{\mathbb{H}}(P, D_{10} 2^{-j})^r 2^{-j} \]
which is bounded in turn by a constant multiple (dependent on \( r \)) of \( [\mathbb{H}] \).
