A GEOMETRIC APPROACH TO GENERALIZED STOKES
CONJECTURES

EUGEN VARVARUCA AND GEORG S. WEISS

Dedicated to John Toland on the occasion of his 60th birthday

Abstract. We consider the Stokes conjecture concerning the shape of extreme two-dimensional water waves. By new geometric methods including a nonlinear frequency formula, we prove the Stokes conjecture in the original variables. Our results do not rely on structural assumptions needed in previous results such as isolated singularities, symmetry and monotonicity. Part of our results extends to the mathematical problem in higher dimensions.

1. Introduction

Consider a two-dimensional inviscid incompressible fluid acted on by gravity and with a free surface. If we denote by $D(t) \subset \mathbb{R}^2$ the domain occupied by the fluid

2000 Mathematics Subject Classification. Primary 35R35, Secondary 76B15, 76B07.

Key words and phrases. Water wave, Stokes conjecture, singularity, frequency formula, concentration compactness.

G.S. Weiss has been partially supported by the Grant-in-Aid 15740100/18740086 of the Japanese Ministry of Education, Culture, Sports, Science and Technology.
at time $t$, then the dynamics of the fluid is described by the Euler equations for the vector velocity field $(u(t,\cdot),v(t,\cdot)) : D(t) \to \mathbb{R}^2$ and the scalar pressure field $P(t,\cdot) : D(t) \to \mathbb{R}$:

$$
\begin{align*}
ut + uu_x + vu_y &= -P_x \quad \text{in } D(t), \\
v_t + uv_x + vv_y &= -P_y - g \quad \text{in } D(t), \\
u_x + v_y &= 0 \quad \text{in } D(t),
\end{align*}
$$

where subscripts denote partial derivatives and $g$ is the gravity constant. The boundary $\partial D(t)$ of the fluid domain contains a part, denoted by $\partial_a D(t)$, which is free and in contact with the air region. The equations of motion are supplemented by the standard kinematic boundary condition

$$
V = (u,v) \cdot \nu \quad \text{on } \partial_a D(t),
$$

where $V$ is the normal speed of $\partial_a D(t)$ and $\nu$ is the outer normal vector, and the dynamic boundary condition

$$
P \text{ is locally constant on } \partial_a D(t).
$$

We further assume that the flow is irrotational:

$$
u_y - v_x = 0 \quad \text{in } D(t).
$$

While recent years have seen great progress in the study of the initial-value problem (see [40] for large-time well-posedness for small data, and the references therein for short-time well-posedness for arbitrary data), in the present paper we confine ourselves to traveling-wave solutions of the above problem, for which there exists $D \subset \mathbb{R}^2$, $c \in \mathbb{R}$, $(\tilde{u},\tilde{v}) : D \to \mathbb{R}^2$ and $\tilde{P} : D \to \mathbb{R}$ such that

$$
D(t) = D + ct(1,0) \quad \text{for all } t \in \mathbb{R},
$$

and for all $t \in \mathbb{R}$ and $(x,y) \in D(t)$,

$$
\begin{align*}
\tilde{u}(x,y,t) = \tilde{u}(x - ct,y) + c, \quad v(x,y,t) = \tilde{v}(x - ct,y), \quad P(x,y,t) = \tilde{P}(x - ct,y).
\end{align*}
$$

Consequently the following equations are satisfied:

$$
\begin{align*}
\tilde{u}u_x + \tilde{v}u_y &= -\tilde{P}_x \quad \text{in } D, \\
\tilde{u}v_x + \tilde{v}v_y &= -\tilde{P}_y - g \quad \text{in } D, \\
\tilde{u}_x + \tilde{v}_y &= 0 \quad \text{in } D, \\
\tilde{u}_y - \tilde{v}_x &= 0 \quad \text{in } D, \\
(\tilde{u},\tilde{v}) \cdot \nu &= 0 \quad \text{on } \partial_a D, \\
\tilde{P} \text{ is locally constant on } \partial_a D.
\end{align*}
$$

The above problem describes both *water waves*, in which case we would add homogeneous Neumann boundary conditions on a flat horizontal bottom $y = -d$ combined with periodicity in the $x$-direction or some condition at $x = \pm \infty$, and
the equally physical problem of the equilibrium state of a fluid when pumping in
water from one lateral boundary and sucking it out at the other lateral boundary.
In the latter setting we would consider a bounded domain with an inhomogeneous
Neumann boundary condition at the lateral boundary, and the bottom could be a
non-flat surface.

In both cases, the incompressibility and the kinematic boundary condition imply
that there exists a stream function $\psi$ in $D$, defined up to a constant by:

$$\psi_x = -\bar{v}, \quad \psi_y = \bar{u} \quad \text{in} \quad D.$$  

It follows that

$\psi$ is locally constant on $\partial_a D$.

The irrotationality condition shows that

$\psi$ is a harmonic function in $D$,

and then Bernoulli’s principle gives that

$$\tilde{P} + \frac{1}{2} |\nabla \psi|^2 + gy \quad \text{is constant in} \quad D.$$  

The dynamic boundary condition implies therefore the Bernoulli condition

$$|\nabla \psi|^2 + 2gy \quad \text{is locally constant on} \quad \partial_a D.$$  

A stagnation point is one at which the relative velocity field $(\bar{u}, \bar{v})$ is zero, and
a wave with stagnation points on the free surface will be referred to as an extreme
wave. Consideration of extreme waves goes back to Stokes, who in 1880 made
the famous conjecture that the free surface of an extreme wave is not smooth at
a stagnation point, but has symmetric lateral tangents forming an angle of 120°.
Stokes [27] gave a formal argument in support of his conjecture, which can be found
at the end of this introduction, but a rigorous proof has not been given until 1982,
when Amick, Fraenkel and Toland [3] and Plotnikov [20] proved the conjecture
independently in brilliant papers. These proofs use an equivalent formulation of
the problem as a nonlinear singular integral equation due to Nekrasov (derived
via conformal mapping), and are based on rather formidable estimates for this
equation. In addition, Plotnikov’s proof uses ordinary differential equations in
the complex plane. Moreover, Plotnikov and Toland proved convexity of the two
branches of the free surface [21]. Prior to these works on the Stokes conjecture,
the existence of extreme periodic waves, of finite and infinite depth, had been
established by Toland [28] and McLeod [18], building on earlier existence results
for large-amplitude smooth waves by Krasovskii [17] and by Keady and Norbury
[16]. Also, the existence of large-amplitude smooth solitary waves and of extreme
solitary waves had been shown by Amick and Toland [4].
In the present paper we confine ourselves to the case when
\[ \Delta \psi = 0 \quad \text{in} \quad D, \]
\[ \psi = 0 \quad \text{on} \quad \partial \alpha D, \]
\[ |\nabla \psi(x,y)|^2 = -y \quad \text{on} \quad \partial \nu D, \]
and we investigate the shape of the free surface \( \partial \alpha D \) close to stagnation points for extreme waves which \textit{a priori} satisfy minimal regularity assumptions. Note that, since \((\tilde{u}, \tilde{v}) = (\psi_y, -\psi_x)\), the Bernoulli condition implies that the free surface is contained in the lower half-plane and that the stagnation points on the free surface necessarily lie on the real axis and are points of maximal height.

Weak solutions of the above free-boundary problem have been studied by Shar-gorodskiy and Toland \cite{25}, and Varvaruca \cite{31}, who consider solutions for which the free surface \( \partial \alpha D \) is a locally rectifiable curve, \( \psi \in C^2(D) \cap C^0(\overline{D}) \) is harmonic and satisfies the zero Dirichlet boundary condition in the classical sense, while the Bernoulli condition is satisfied almost everywhere with respect to the one-dimensional Hausdorff measure by the non-tangential limits of \( \nabla \psi \). They prove that the set \( S \) of stagnation points on the free surface is a set of zero one-dimensional Hausdorff measure, that \( \partial \alpha D \setminus S \) is a union of real-analytic arcs, and that \( \psi \) has a harmonic extension across \( \partial \alpha D \setminus S \) which satisfies all free-boundary conditions in the classical sense outside stagnation points.

The main objectives of the present paper are to give affirmative answers to the following two questions:

(i) Does the set \( S \) consist only of isolated points?

(ii) Is the Stokes Conjecture valid at each point of \( S \)?

Prior to our work, Question (i) has been completely open, while the answer to Question (ii) has been known only partially: from \cite{3} and \cite{20} which have recently been simplified in \cite{30} and \cite{32}, we know (ii) to be true at those points of \( S \) which satisfy the following conditions in a neighborhood of the stagnation point: The stagnation point is isolated, the free surface is symmetric with respect to the vertical line passing through the stagnation point, it is a monotone graph on each side of that point, and \( \psi \) is strictly decreasing in the \( y \)-direction in \( D \). All of these conditions are essential for the proofs in the cited results. Let us mention that from the point of view of applications, the requirement of symmetry is most inconvenient, as numerical results indicate the existence of nonsymmetric extreme waves \cite{7} \cite{29} \cite{41}. Also, for waves with non-zero vorticity, \( \psi \) need not be monotone in the \( y \)-direction \cite{34} \cite{10}.

Similarly to \cite{25} and \cite{31}, we consider weak solutions which are roughly speaking solutions in the sense of distributions. The precise notion will be given in Definition \cite{42}. We assume that \( \psi > 0 \) in \( D \), and we extend \( \psi \) by the value 0 to the air region so that the fluid domain can be identified with the set \( \{ \psi > 0 \} \). Since our arguments
are local, we work in a bounded domain $\Omega$ which has a non-empty intersection with the real axis and on which there is defined a continuous function $\psi$ such that, within $\Omega$, $\{\psi > 0\}$ corresponds to the fluid region and $\{\psi = 0\}$ to the air region, the part of $\Omega$ in the upper half-plane being occupied by air.

In the case of only a finite number of connected components of the air region we recover the Stokes conjecture by geometric methods (Theorem 11.2), without assuming isolatedness, symmetry or any monotonicity:

**Theorem A.** Let $\psi$ be a weak solution of

$$
\Delta \psi = 0 \quad \text{in } \Omega \cap \{\psi > 0\},
$$

$$
|\nabla \psi|^2 = -y \quad \text{on } \Omega \cap \partial \{\psi > 0\},
$$

and suppose that

$$
|\nabla \psi|^2 \leq -y \quad \text{in } \Omega \cap \{\psi > 0\}.
$$

Suppose moreover that $\{\psi = 0\}$ has locally only finitely many connected components. Then the set $S$ of stagnation points is locally in $\Omega$ a finite set. At each stagnation point $(x_0, y_0)$ the scaled solution converges to the Stokes corner flow, that is,

$$
\frac{\psi((x^0, y^0) + r(x, y))}{r^{3/2}} \rightarrow \frac{\sqrt{2}}{3} \rho^{3/2} \max(\cos(3(\theta + \pi/2)/2), 0) \quad \text{as } r \rightarrow 0,
$$

strongly in $W^{1,2}_{\text{loc}}(\mathbb{R}^2)$ and locally uniformly on $\mathbb{R}^2$, where $(x, y) = (\rho \cos \theta, \rho \sin \theta)$, and in an open neighborhood of $(x^0, y^0)$ the topological free boundary $\partial \{\psi > 0\}$ is the union of two $C^1$-graphs with right and left tangents at $(x^0, y^0)$.

Let us remark that the assumption

$$
|\nabla \psi|^2 \leq -y \quad \text{in } \{\psi > 0\}
$$

has been verified in [31, Proof of Theorem 3.6] for weak solutions, in the sense of [25] and [31] described earlier, of the water-problem in all its classical versions: periodic and solitary waves of finite depth (in which the fluid domain has a fixed flat bottom $y = -d$, at which $\psi$ is constant), and periodic waves of infinite depth (in which the fluid domain extends to $y = -\infty$ and the condition $\lim_{y \to -\infty} \nabla \psi(x, y) = (0, -c)$ holds, where $c$ is the speed of the wave). The proof is merely an extension of that of Spielvogel [26, Proof of Theorem 3b] for classical solutions, which is based on the Bernstein technique.

In the case of an infinite number of connected components of the air region, we obtain the following result (cf. Theorem 11.1):

**Theorem B.** Let $\psi$ be a weak solution of

$$
\Delta \psi = 0 \quad \text{in } \Omega \cap \{\psi > 0\},
$$

$$
|\nabla \psi|^2 = -y \quad \text{on } \Omega \cap \partial \{\psi > 0\},
$$

and suppose

$$
|\nabla \psi|^2 \leq -y \quad \text{in } \{\psi > 0\}.
$$

Suppose moreover that $\{\psi = 0\}$ has locally only finitely many connected components. Then the set $S$ of stagnation points is locally in $\Omega$ a finite set. At each stagnation point $(x_0, y_0)$ the scaled solution converges to the Stokes corner flow, that is,

$$
\frac{\psi((x^0, y^0) + r(x, y))}{r^{3/2}} \rightarrow \frac{\sqrt{2}}{3} \rho^{3/2} \max(\cos(3(\theta + \pi/2)/2), 0) \quad \text{as } r \rightarrow 0,
$$

strongly in $W^{1,2}_{\text{loc}}(\mathbb{R}^2)$ and locally uniformly on $\mathbb{R}^2$, where $(x, y) = (\rho \cos \theta, \rho \sin \theta)$, and in an open neighborhood of $(x^0, y^0)$ the topological free boundary $\partial \{\psi > 0\}$ is the union of two $C^1$-graphs with right and left tangents at $(x^0, y^0)$.
and suppose that

$$|\nabla \psi|^2 \leq -y \quad \text{in } \Omega \cap \{\psi > 0\}.$$ 

Then the set $S$ of stagnation points is a finite or countable set. Each accumulation point of $S$ is a point of the locally finite set $\Sigma$ described in more detail in the following lines.

At each point $(x^0, y^0)$ of $S \setminus \Sigma$,

$$\frac{\psi((x^0, y^0) + r(x, y))}{r^{3/2}} \to \frac{\sqrt{2}}{3} \max\{\cos(3\theta + \pi/2)/2, 0\} \quad \text{as } r \to 0,$$

strongly in $W^{1,2}_{\text{loc}}(\mathbb{R}^2)$ and locally uniformly on $\mathbb{R}^2$, where $(x, y) = (\rho \cos \theta, \rho \sin \theta)$.

The scaled free surface converges to that of the Stokes corner flow in the sense that, as $r \to 0$,

$$L^2(B_1 \cap \{(x, y) : \psi((x^0, y^0) + r(x, y)) > 0 \} \cap \{\cos(3\theta + \pi/2)/2 > 0\}) \to 0.$$

At each point $(x^0, y^0)$ of $\Sigma$ there exists an integer $N = N(x^0, y^0) \geq 2$ such that

$$\frac{\psi((x^0, y^0) + r(x, y))}{r^{\beta}} \to 0 \quad \text{as } r \to 0,$$

strongly in $L^2_{\text{loc}}(\mathbb{R}^2)$ for each $\beta \in [0, N)$, and

$$\sqrt{\frac{1}{r-1} \int_{\partial B_r((x^0, y^0))} \psi^2 \, d\mathcal{H}^1} \to \frac{\rho^N |\sin(N\theta)|}{\sqrt{\int_0^{2\pi} \sin^2(N\theta) \, d\theta}} \quad \text{as } r \to 0,$$

strongly in $W^{1,2}_{\text{loc}}(B_1 \setminus \{0\})$ and weakly in $W^{1,2}(B_1)$, where $(x, y) = (\rho \cos \theta, \rho \sin \theta)$.

Although the new dynamics suggested by Theorem B at degenerate points cannot happen in the case of a finite number of air components, there seems to be no obvious reason precluding the scenario in Figure 1 with an infinite number of air components, and the situation is even less clear in the case of inhomogeneous Neumann boundary conditions. Note that multiple air components without surface tension have previously been considered in [13]. It is noteworthy that while the water wave problem has a variational structure, the solutions of interest are
not minimisers of the energy functional. Consequently, standard methods in free-boundary problems based on non-degeneracy, which would in the present case be the estimate
\[
\int_{\partial B_1((0,0))} \frac{\psi((x^0, y^0) + r(x, y))}{r^{3/2}} d\mathcal{H}^1 \geq c_1 > 0 \quad \text{for all } r \in (0, r_0),
\]
do not apply.

As far as the water-wave problem is concerned, the new perspective of our approach is that we work with the original variables \((\tilde{u}, \tilde{v})\) and use geometric methods as for example a blow-up analysis in order to show that the scaled solution is close to a homogeneous function. This part of the blow-up analysis works in \(n\) dimensions and does not require \textit{ad hoc} methods previously applied to classify global solutions (see for example [32]). This also means that we do not require isolated singularities, symmetry or monotonicity which had been assumed in all previous results. Original tools in the present paper include the new Frequency Formula (Theorem 7.1) which allows a blow-up analysis at degenerate points, where the scaling of the solution is different from the invariant scaling of the equation, and leads in combination with the result [12] by Evans and Müller to concentration compactness (Theorem 10.1).

Large parts of the paper are written down for the non-physical but mathematically interesting free-boundary problem in \(n\) dimensions; see for example the partial regularity result Proposition 5.8 showing that non-degenerate stagnation points form a set of dimension less or equal than \(n - 2\).

Our methods can still be applied when dropping the condition of irrotationality of the flow (see [32], the forthcoming papers [33] and [23], and [8, 9] for a background on water waves with vorticity). Part of the methods extend even to water waves with surface tension (see the forthcoming paper [39]).

It is interesting to observe that in his formal proof of the conjecture, Stokes worked with the original variables \((\tilde{u}, \tilde{v})\) and approximated the velocity potential (the harmonic conjugate of \(-\psi\)) by a \textit{homogeneous function}. This is very close in spirit to what we do on a rigorous level in the Monotonicity Formula (Theorem 3.5) and the Frequency Formula (Theorem 7.1), so let us close our introduction with a quotation taken from [27, p. 226–227]:

Reduce the wave motion to steady motion by superposing a velocity equal and opposite to that of propagation. Then a particle at the surface may be thought of as gliding along a fixed smooth curve: this follows directly from physical considerations, or from the ordinary equation of steady motion. On arriving at a crest the particle must be momentarily at rest, and on passing it must be ultimately in the condition of a particle starting from rest down an inclined or vertical plane. Hence the velocity must vary ultimately as the square root of the distance from the crest.
Hitherto the motion has been rotational or not, let us now confine ourselves to the case of irrotational motion. Place the origin at the crest, refer the function $\phi$ to polar coordinates $r, \theta$; $\theta$ being measured from the vertical, and consider the value of $\phi$ very near the origin, where $\phi$ may be supposed to vanish, as the arbitrary constant may be omitted. In general $\phi$ will be of the form $\sum A_n r^n \sin n\theta + \sum B_n r^n \cos n\theta$. In the present case $\phi$ must contain sines only on account of the symmetry of the motion, as already shown (p. 212), so that retaining only the most important term we may take $\phi = A r^n \sin n\theta$. Now for a point in the section of the profile we must have $d\phi/d\theta = 0$, and $d\phi/d\theta$ varying ultimately as $r^{1/2}$. This requires $n = 3/2$, and for the profile that $3\theta/2 = \pi/2$, so that the two branches are inclined at angles of $\pm 60^\circ$ to the vertical, and at an angle of $120^\circ$ to each other, not of $90^\circ$ as supposed by Rankine.

Acknowledgment. We are very grateful to Stefan Müller, Pavel Plotnikov, John Toland and Yoshihiro Tonegawa for helpful suggestions and discussions.

2. Notation

We denote by $\chi_A$ the characteristic function of the set $A$, and by $A \triangle B$ the set $(A \setminus B) \cup (B \setminus A)$. For any real number $a$, the notation $a^+$ stands for $\max(a, 0)$. We denote by $x \cdot y$ the Euclidean inner product in $\mathbb{R}^n \times \mathbb{R}^n$, by $|x|$ the Euclidean norm in $\mathbb{R}^n$ and by $B_r(x^0) := \{ x \in \mathbb{R}^n : |x - x^0| < r \}$ the ball of center $x^0$ and radius $r$. We will use the notation $B_r$ for $B_r(0)$, and denote by $\omega_n$ the $n$-dimensional volume of $B_1$. Also, $\mathcal{L}^n$ shall denote the $n$-dimensional Lebesgue measure and $\mathcal{H}^s$ the $s$-dimensional Hausdorff measure. By $\nu$ we will always refer to the outer normal on a given surface. We will use functions of bounded variation $BV(U)$, i.e. functions $f \in L^1(U)$ for which the distributional derivative is a vector-valued Radon measure. Here $|\nabla f|$ denotes the total variation measure (cf. [15]). Note that for a smooth open set $E \subset \mathbb{R}^n$, $|\nabla \chi_E|$ coincides with the surface measure on $\partial E$. Last, we will use the notation $r \searrow 0$ in the meaning of $r \rightarrow 0^+$ and $r \nearrow 0$ in the meaning of $r \rightarrow 0^-$.  

3. Notion of solution and monotonicity formula

Throughout the rest of the paper we work with a $n$-dimensional generalization of the problem described in the Introduction. Let $\Omega$ be a bounded domain in $\mathbb{R}^n$ which has a non-empty intersection with the hyperplane $\{ x_n = 0 \}$, in which to consider the combined problem for fluid and air. We study solutions $u$, in a sense
to be specified, of the problem

\[ \Delta u = 0 \quad \text{in } \Omega \cap \{u > 0\}, \]
\[ |\nabla u|^2 = x_n \quad \text{on } \Omega \cap \partial\{u > 0\}. \tag{3.1} \]

(Note that, compared to the Introduction, we have switched notation from \(\psi\) to \(u\) and we have “reflected” the problem at the hyperplane \(\{x_n = 0\}\).) Since our results are completely local, we do not specify boundary conditions on \(\partial\Omega\).

We begin by introducing our notion of a variational solution of problem (3.1).

**Definition 3.1 (Variational Solution).** We define \(u \in W^{1,2}_{\text{loc}}(\Omega)\) to be a variational solution of (3.1) if \(u \in C^0(\Omega) \cap C^2(\Omega \cap \{u > 0\})\), \(u \geq 0\) in \(\Omega\) and \(u \equiv 0\) in \(\Omega \cap \{x_n \leq 0\}\), and the first variation with respect to domain variations of the functional

\[ J(v) := \int_\Omega \left(|\nabla v|^2 + x_n \chi_{\{v>0\}}\right) \]

vanishes at \(v = u\), i.e.

\[ 0 = -\frac{d}{d\epsilon} J(u(x + \epsilon \phi(x)))|_{\epsilon=0} \]
\[ = \int_\Omega \left(|\nabla u|^2 \text{div } \phi - 2\nabla u D\phi \nabla u + x_n \chi_{\{u>0\}} \text{div } \phi + \chi_{\{u>0\}} \phi_n\right) \]

for any \(\phi \in C^1_0(\Omega; \mathbb{R}^n)\).

The assumption \(u \in C^0(\Omega) \cap C^2(\Omega \cap \{u > 0\})\) is necessary in that it cannot be deduced from the other assumptions in Definition 3.1 by regularity theory, but it is rather mild in the sense that it can be verified without effort for “reasonable” solutions, for example solutions obtained by a diffuse interface approximation. Also we like to emphasise that regularity properties of the free boundary, like for example finite perimeter, are not required at all. Note for future reference that the fact that \(u\) continuous and nonnegative in \(\Omega\), as well as harmonic in \(\{u > 0\}\), implies that \(\Delta u\) is a nonnegative Radon measure in \(\Omega\) with support on \(\Omega \cap \partial\{u > 0\}\).

We will also use weak solutions of (3.1), i.e. solutions in the sense of distributions. For a comparison of variational and weak solutions see Lemma 3.4.

**Definition 3.2 (Weak Solution).** We define \(u \in W^{1,2}_{\text{loc}}(\Omega)\) to be a weak solution of (3.1) if the following are satisfied: \(u \in C^0(\Omega)\), \(u \geq 0\) in \(\Omega\) and \(u \equiv 0\) in \(\Omega \cap \{x_n \leq 0\}\), \(u\) is harmonic in \(\{u > 0\} \cap \Omega\) and, for every \(\tau > 0\), the topological free boundary \(\partial\{u > 0\} \cap \Omega \cap \{x_n > \tau\}\) can be locally decomposed into an \(n-1\)-dimensional \(C^2\)-surface, relatively open to \(\partial\{u > 0\}\) and denoted by \(\partial_{\text{red}}\{u > 0\}\), and a singular set of vanishing \(H^{n-1}\)-measure: for an open neighborhood \(V\) of each point \(x^0 \in \Omega \cap \{x_n > \tau\}\) of \(\partial_{\text{red}}\{u > 0\}\), \(u \in C^1(V \cap \{u > 0\})\) satisfies

\[ |\nabla u(x)|^2 = x_n \quad \text{on } V \cap \partial_{\text{red}}\{u > 0\}. \]
Remark 3.3. (i) By [22, Theorem 8.4], the weak solutions in [22] with $Q(x) = x_n^+$ satisfy Definition 3.2.

(ii) By [31, Theorem 3.5], the weak solutions in [25, 31] satisfy Definition 3.2.

Lemma 3.4. Any weak solution of (3.1) such that

$$|\nabla u|^2 \leq Cx_n^+ \text{ locally in } \Omega,$$

is a variational solution of (3.1). Moreover, $\chi_{\{u > 0\}}$ is locally in $\{x_n > 0\}$ a function of bounded variation, and the total variation measure $|\nabla \chi_{\{u > 0\}}|$ satisfies

$$r^{1/2-n} \int_{B_r(y)} \sqrt{x_n} |\nabla \chi_{\{u > 0\}}| \leq C_0$$

for all $B_r(y) \subset\subset \Omega$ such that $y_n = 0$.

The proof follows [36, Theorem 5.1] and will be done in the Appendix.

A first tool in our analysis is an extension of the monotonicity formula in [37], [36, Theorem 3.1] to the boundary case. The roots of those monotonicity formulas are harmonic mappings [24], [22] and blow-up [19].

Theorem 3.5 (Monotonicity Formula). Let $u$ be a variational solution of (3.1), let $x^0 \in \Omega$, and let $\delta := \text{dist}(x^0, \partial \Omega)/2$.

(i) Interior Case $x_n^0 \geq 0$: The function

$$\Phi^\text{int}_{x^0, u}(r) := r^{-n} \int_{B_r(x^0)} (|\nabla u|^2 + x_n \chi_{\{u > 0\}}) - r^{-n-1} \int_{\partial B_r(x^0)} u^2 dH^{n-1},$$

defined in $(0, \delta)$, satisfies the formula

$$\Phi^\text{int}_{x^0, u}(\sigma) - \Phi^\text{int}_{x^0, u}(\rho) = \int_{\rho}^{\sigma} r^{-n} \int_{\partial B_r(x^0)} 2 \left( \nabla u \cdot \nu - \frac{u}{r} \right)^2 dH^{n-1} dr$$

$$+ \int_{\rho}^{\sigma} r^{-n-1} \int_{B_r(x^0)} \left( x_n - x_n^0 \right) \chi_{\{u > 0\}} dx dr,$$

for any $0 < \rho < \sigma < \delta$. The absolute value of the second term of the right-hand side is estimated by $\sigma - \rho$ and is therefore $O(\sigma)$.

(ii) Boundary Case $x_n^0 = 0$: The function

$$\Phi^\text{bound}_{x^0, u}(r) := r^{-n-1} \int_{B_r(x^0)} (|\nabla u|^2 + x_n \chi_{\{u > 0\}}) - \frac{3}{2} r^{-n-2} \int_{\partial B_r(x^0)} u^2 dH^{n-1},$$

defined in $(0, \delta)$, satisfies the formula

$$\Phi^\text{bound}_{x^0, u}(\sigma) - \Phi^\text{bound}_{x^0, u}(\rho) = \int_{\rho}^{\sigma} r^{-n-1} \int_{\partial B_r(x^0)} 2 \left( \nabla u \cdot \nu - \frac{3 u}{2 r} \right)^2 dH^{n-1} dr,$$

for any $0 < \rho < \sigma < \delta$. 

Remark 3.6. Let us assume that \( x^0 = 0 \). Then the integrand on the right-hand side of the Monotonicity Formula is a scalar multiple of \( (\nabla u(x) \cdot x - \frac{1}{2} u(x))^2 \), and therefore vanishes if and only if \( u \) is a homogeneous function of degree 3/2.

Proof of Theorem 3.3. We start with a general observation: for any \( u \in W_{\text{loc}}^{1,2}(\Omega) \) and \( \alpha \in \mathbb{R} \), the following identity holds a.e. on \((0, \delta)\), where \( w_r(x) = u(x^0 + r x) \):

\[
\frac{d}{dr} \left( r^\alpha \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1} \right) = \frac{d}{dr} \left( r^{\alpha+n-1} \int_{\partial B_r} w_r^2 \, d\mathcal{H}^{n-1} \right) \tag{3.2}
\]

\[
= (\alpha + n - 1) r^{\alpha-1} \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1} + r^{\alpha+n-1} \int_{\partial B_r} 2w_r \nabla u(x^0 + r x) \cdot x \, d\mathcal{H}^{n-1} - (\alpha + n - 1) r^{\alpha-1} \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1} + r^{\alpha} \int_{\partial B_r(x^0)} 2u \nabla u \cdot \nu \, d\mathcal{H}^{n-1}.
\]

Suppose now that \( u \) is a variational solution of (3.1). For small positive \( \kappa \) and \( \eta_\kappa(t) := \max(0, \min(1, \frac{t-1}{\kappa})) \), we take after approximation \( \phi_\kappa(x) := \eta_\kappa(|x-x^0|)(x-x^0) \) as a test function in the definition of a variational solution. We obtain

\[
0 = \int_\Omega (|\nabla u|^2 + x_n \chi_{\{u>0\}}) \left( \eta_\kappa(|x-x^0|) + \eta'_\kappa(|x-x^0|)|x-x^0| \right) - 2 \int_\Omega \nabla u \cdot \frac{x-x^0}{|x-x^0|} \nabla u \cdot \frac{x-x^0}{|x-x^0|} \eta'_\kappa(|x-x^0|)|x-x^0| + \int_\Omega \eta_\kappa(|x-x^0|)(x_n-x^0_n)\chi_{\{u>0\}}.
\]

Passing to the limit as \( \kappa \to 0 \), we obtain, for a.e. \( r \in (0, \delta) \),

\[
0 = n \int_{B_r(x^0)} (|\nabla u|^2 + x_n \chi_{\{u>0\}}) \tag{3.3}
- r \int_{\partial B_r(x^0)} (|\nabla u|^2 + x_n \chi_{\{u>0\}}) \, d\mathcal{H}^{n-1}
+ 2r \int_{\partial B_r(x^0)} (\nabla u \cdot \nu)^2 \, d\mathcal{H}^{n-1} - 2 \int_{B_r(x^0)} |\nabla u|^2 \, d\mathcal{H}^{n-1}
+ \int_{B_r(x^0)} (x_n-x^0_n)\chi_{\{u>0\}}.
\]

Observe that letting \( \epsilon \to 0 \) in

\[
\int_{B_r(x^0)} \nabla u \cdot \nabla \max(u - \epsilon, 0)^{1+\epsilon} = \int_{\partial B_r(x^0)} \max(u - \epsilon, 0)^{1+\epsilon} \nabla u \cdot \nu \, d\mathcal{H}^{n-1}
\]

for a.e. \( r \in (0, \delta) \), we obtain the integration by parts formula

\[
\int_{B_r(x^0)} |\nabla u|^2 = \int_{\partial B_r(x^0)} u \nabla u \cdot \nu \, d\mathcal{H}^{n-1} \tag{3.4}
\]

for a.e. \( r \in (0, \delta) \).
Now let for all \( r \in (0, \delta) \),
\[
U_{\text{int}}(r) := r^{-n} \int_{B_r(x^0)} \left( |\nabla u|^2 + x_n \chi_{\{u > 0\}} \right),
\]
\[
W_{\text{int}}(r) := r^{-n-1} \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1},
\]
so that \( \Phi_{x^0,u}^{\text{int}} = U_{\text{int}} - W_{\text{int}} \). Note that, for a.e. \( r \in (0, \delta) \),
\[
U_{\text{int}}'(r) = -nr^{-n-1} \int_{B_r(x^0)} \left( |\nabla u|^2 + x_n \chi_{\{u > 0\}} \right) + r^{-n} \int_{\partial B_r(x^0)} \left( |\nabla u|^2 + x_n \chi_{\{u > 0\}} \right) d\mathcal{H}^{n-1}.
\]
It follows, using (3.3) and (3.4), that for a.e. \( r \in (0, \delta) \),
\[
U_{\text{int}}''(r) = 2r^{-n} \int_{\partial B_r(x^0)} (\mathbf{\nabla} u \cdot \nu)^2 \, d\mathcal{H}^{n-1} - 2r^{-n-1} \int_{\partial B_r(x^0)} u \mathbf{\nabla} u \cdot \nu \, d\mathcal{H}^{n-1} - 2r^{-n} \int_{\partial B_r(x^0)} (x_n - x_n^0) \chi_{\{u > 0\}}.
\]
On the other hand, plugging \( \alpha := -n-1 \) into (3.2), we obtain that for a.e. \( r \in (0, \delta) \),
\[
W_{\text{int}}''(r) = 2r^{-n-1} \int_{\partial B_r(x^0)} u \mathbf{\nabla} u \cdot \nu \, d\mathcal{H}^{n-1} - 2r^{-n-2} \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1}.
\]
Combining (3.5) and (3.6) yields (i).

Next, let for all \( r \in (0, \delta) \),
\[
U_{\text{bound}}(r) := r^{-n} \int_{B_r(x^0)} \left( |\nabla u|^2 + x_n \chi_{\{u > 0\}} \right),
\]
\[
W_{\text{bound}}(r) := r^{-n-2} \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1},
\]
so that \( \Phi_{x^0,u}^{\text{bound}} = U_{\text{bound}} - 3/2 W_{\text{bound}} \). Now observe that, in the case when \( x_n^0 = 0 \), formula (3.4) means that
\[
0 = (n + 1) \int_{B_r(x^0)} \left( |\nabla u|^2 + x_n \chi_{\{u > 0\}} \right) - r \int_{\partial B_r(x^0)} \left( |\nabla u|^2 + x_n \chi_{\{u > 0\}} \right) d\mathcal{H}^{n-1} + 2r \int_{\partial B_r(x^0)} (\mathbf{\nabla} u \cdot \nu)^2 \, d\mathcal{H}^{n-1} - 3 \int_{B_r(x^0)} |\nabla u|^2.
\]
Also, for a.e. \( r \in (0, \delta) \),
\[
U_{\text{bound}}'(r) = -((n + 1)r^{-n-2} \int_{B_r(x^0)} \left( |\nabla u|^2 + x_n \chi_{\{u > 0\}} \right) + r^{-n-1} \int_{\partial B_r(x^0)} \left( |\nabla u|^2 + x_n \chi_{\{u > 0\}} \right)
\]
It follows, using (3.7) and (3.8), that for a.e. \( r \in (0, \delta) \),
\[
U'_{\text{bound}}(r) = 2r^{-n-1} \int_{\partial B_r(x^0)} (\nabla u \cdot \nu)^2 \, d\mathcal{H}^{n-1} - 3r^{-n-2} \int_{\partial B_r(x^0)} u \nabla u \cdot \nu \, d\mathcal{H}^{n-1}.
\] (3.8)

On the other hand, plugging \( \alpha := -n-2 \) into (3.2), we obtain that for a.e. \( r \in (0, \delta) \),
\[
W'_{\text{bound}}(r) = 2r^{-n-2} \int_{\partial B_r(x^0)} u \nabla u \cdot \nu \, d\mathcal{H}^{n-1} - 3r^{-n-3} \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1}.
\] (3.9)

Combining (3.8) and (3.9) yields (ii).

\[\square\]

4. Densities

From Theorem 3.5 we infer that the functions \( \Phi_{\text{int}}^{x^0,u} \) and \( \Phi_{\text{bound}}^{x^0,u} \) have right limits
\[
\phi_{\text{int}}^{x^0,u}(0+) = \lim_{r \searrow 0} \Phi_{\text{int}}^{x^0,u}(r) \in [-\infty, \infty), \quad \phi_{\text{bound}}^{x^0,u}(0+) = \lim_{r \searrow 0} \Phi_{\text{bound}}^{x^0,u}(r) \in [-\infty, \infty).
\]

In this section we derive structural properties of these “densities”
\[
\Phi_{\text{int}}^{x^0,u}(0+), \Phi_{\text{bound}}^{x^0,u}(0+).
\]

The term “density” is justified somewhat by Lemma 4.2 (i), (ii).

Note that most of the statements concerning \( \Phi_{\text{int}}^{x^0,u} \) will not be used in subsequent sections but serve to illustrate differences between the boundary and interior case.

**Lemma 4.1.** Let \( u \) be a variational solution of (3.1) and suppose that
\[
|\nabla u|^2 \leq Cx_n^+ \quad \text{locally in } \Omega.
\]

Then:

(i) Let \( x^0 \in \Omega \) be such that \( x_n^0 > 0 \). Then \( \Phi_{\text{int}}^{x^0,u}(0+) \) is finite if \( u(x^0) = 0 \), and \( \Phi_{\text{int}}^{x^0,u}(0+) = -\infty \) otherwise.

(ii) Let \( x^0 \in \Omega \) be such that \( x_n^0 = 0 \). Then \( \Phi_{\text{bound}}^{x^0,u}(0+) \) is finite. (Note that \( u = 0 \) in \( \{x_n = 0\} \) by assumption.)

(iii) Let \( x^0 \in \Omega \) be such that \( x_n^0 > 0 \) and \( u(x^0) = 0 \), and let \( 0 < r_m \searrow 0 \) as \( m \to \infty \) be a sequence such that the blow-up sequence
\[
u_m(x) := u(x^0 + r_mx)/r_m
\]
converges weakly in \( W^{1,2}_{\text{loc}}(\mathbb{R}^n) \) to a blow-up limit \( u_0 \). Then \( u_0 \) is a homogeneous function of degree 1, i.e. \( u_0(\lambda x) = \lambda u_0(x) \).

(iv) Let \( x^0 \in \Omega \) be such that \( x_n^0 = 0 \), and let \( 0 < r_m \searrow 0 \) as \( m \to \infty \) be a sequence such that the blow-up sequence
\[
u_m(x) := u(x^0 + r_mx)/r_m^{3/2}
\]
converges weakly in \( W^{1,2}_{\text{loc}}(\mathbb{R}^n) \) to a blow-up limit \( u_0 \). Then \( u_0 \) is a homogeneous function of degree 3/2, i.e. \( u_0(\lambda x) = \lambda^{3/2}u_0(x) \).
\((v)\) Let \(u_m\) be a converging sequence of (iii) or (iv). Then \(u_m\) converges strongly in \(W^{1,2}_{\text{loc}}(\mathbb{R}^n)\).

Proof. (i),(ii): If \(u(x^0) = 0\), the finiteness claims follow directly from the growth assumption \(|\nabla u|^2 \leq Cx_n^+\). If \(x_n^0 > 0\) and \(u(x^0) > 0\), then, since \(|\nabla u|^2 \leq Cx_n^+\) by assumption, we obtain that \(\Phi_{x^0,u}^{\text{int}}(r) \leq C_1 - C_2 r^{-2}\) for \(r \leq r_0\), implying that \(\Phi_{x^0,u}(0+) = -\infty\).

(iii),(iv): For each \(0 < \sigma < \infty\) the sequence \(u_m\) is by assumption bounded in \(C^{0,1}(B_\sigma)\). From the Monotonicity Formula (Theorem 3.5) we infer therefore, setting \(\alpha = 1\) in the interior case and \(\alpha = 3/2\) in the boundary case, that for all \(0 < \rho < \sigma < \infty\),
\[
\int_\sigma^\rho \int_{\partial B_r} (\nabla u_m(x) \cdot x - \alpha u_m(x))^2 \, d\mathcal{H}^{n-1} \, dr \to 0 \quad \text{as} \quad m \to \infty,
\]
which yields the desired homogeneity of \(u_0\).

(v): The proof follows [6, Lemma 7.2]. In order to show strong convergence of \(u_m\) in \(W^{1,2}_{\text{loc}}(\mathbb{R}^n)\), it is sufficient, in view of the weak \(L^2\)-convergence of \(\nabla u_m\), to show that
\[
\limsup_{m \to \infty} \int_{\mathbb{R}^n} |\nabla u_m|^2 \eta \leq \int_{\mathbb{R}^n} |\nabla u_0|^2 \eta
\]
for each \(\eta \in C^1_0(\mathbb{R}^n)\). Using the uniform convergence, the continuity of \(u_0\), as well as the fact that \(u_0\) is harmonic in \(\{u_0 > 0\}\), we obtain as in the proof of [3.1] that
\[
\int_{\mathbb{R}^n} |\nabla u_m|^2 \eta = -\int_{\mathbb{R}^n} u_m \nabla u_m \cdot \nabla \eta \to -\int_{\mathbb{R}^n} u_0 \nabla u_0 \cdot \nabla \eta = \int_{\mathbb{R}^n} |\nabla u_0|^2 \eta
\]
as \(m \to \infty\). It follows that \(u_m\) converges to \(u_0\) strongly in \(W^{1,2}_{\text{loc}}(\mathbb{R}^n)\) as \(m \to \infty\). \(\square\)

Lemma 4.2. Let \(u\) be a variational solution of (3.1) and suppose that

\(|\nabla u|^2 \leq Cx_n^+\) locally in \(\Omega\).

Then:

(i) Let \(x_n^0 \in \Omega\), be such that \(x_n^0 > 0\) and \(u(x^0) = 0\). Then
\[
\Phi_{x^0,u}^{\text{int}}(0+) = \lim_{r \to 0} r^{-n} \int_{B_r(x^0)} \chi_{\{u > 0\}},
\]
and in particular \(\Phi_{x^0,u}^{\text{int}}(0+) \in [0, +\infty)\). Moreover, \(\Phi_{x^0,u}^{\text{int}}(0+) = 0\) implies that \(u_0 = 0\) in \(\mathbb{R}^n\) for each blow-up limit \(u_0\) of Lemma 4.1 (iii).

(ii) Let \(x_n^0 \in \Omega\), be such that \(x_n^0 = 0\). Then
\[
\Phi_{x^0,u}^{\text{bound}}(0+) = \lim_{r \to 0} r^{-n-1} \int_{B_r(x^0)} x_n^+ \chi_{\{u > 0\}},
\]
and in particular \(\Phi_{x^0,u}^{\text{bound}}(0+) \in [0, +\infty)\). Moreover, \(\Phi_{x^0,u}^{\text{bound}}(0+) = 0\) implies that \(u_0 = 0\) in \(\mathbb{R}^n\) for each blow-up limit \(u_0\) of Lemma 4.1 (iv).

(iii) The function \(x \mapsto \Phi_{x^0,u}^{\text{int}}(0+)\) is upper semicontinuous in \(\{x_n > 0\}\).

(iv) The function \(x \mapsto \Phi_{x^0,u}^{\text{bound}}(0+)\) is upper semicontinuous in \(\{x_n = 0\}\).
(v) Let $u_m$ be a sequence of variational solutions of (3.1) which converges strongly to $u_0$ in $W^{1,2}_{\text{loc}}(\mathbb{R}^n)$ and such that $\chi_{\{u_m > 0\}}$ converges weakly in $L^2_{\text{loc}}(\mathbb{R}^n)$ to $\chi_0$. Then $u_0$ is a variational solution of (3.1) and satisfies the Monotonicity Formula, but with $\chi_{\{u_0 > 0\}}$ replaced by $\chi_0$. Moreover, for each $x^0 \in \Omega$, and all instances of $\chi_{\{u_0 > 0\}}$ replaced by $\chi_0$,

$$
\Phi_{x^0, u_0}^\text{int} (0+) \geq \limsup_{m \to \infty} \Phi_{x^0, u_m}^\text{int} (0+)
$$

in the interior case $x^0_n > 0$, and

$$
\Phi_{x^0, u_0}^\text{int} (0+) \geq \limsup_{m \to \infty} \Phi_{x^0, u_m}^\text{int} (0+)
$$

in the boundary case $x^0_n = 0$.

Proof. (i),(ii): Let us take a sequence $r_m \downarrow 0$ such that $u_m$ defined in Lemma 4.1 (iii), (iv) converges weakly in $W^{1,2}_{\text{loc}}(\mathbb{R}^n)$ to a function $u_0$. Using Lemma 4.1 (v) and the homogeneity of $u_0$, in the interior case we obtain that

$$
\lim_{m \to \infty} \Phi_{x^0, u}^\text{int} (r_m) = \int_{B_1} |\nabla u_0|^2 - \int_{\partial B_1} u_0^2 \, d\mathcal{H}^{n-1} + \int_{\mathcal{R}(x^0)} x_n^0 \lim_{r \to 0} r^{-n} \int_{B_r(x^0)} \chi_{\{u > 0\}}
$$

$$
= x_n^0 \lim_{r \to 0} r^{-n} \int_{B_r(x^0)} \chi_{\{u > 0\}}.
$$

(the limit here exists because $\lim_{r \to 0} \Phi_{x^0, u}^\text{int} (r)$ exists), while in the boundary case we obtain that

$$
\lim_{m \to \infty} \Phi_{x^0, u}^\text{bound} (r_m) = \int_{B_1} |\nabla u_0|^2 - \frac{3}{2} \int_{\partial B_1} u_0^2 \, d\mathcal{H}^{n-1} + \lim_{r \to 0} r^{-n-1} \int_{B_r(x^0)} x_n^0 \chi_{\{u > 0\}}
$$

$$
= \lim_{r \to 0} r^{-n-1} \int_{B_r(x^0)} x_n^0 \chi_{\{u > 0\}}.
$$

Thus $\Phi_{x^0, u}^\text{int} (0+) \geq 0$ in the interior case, $\Phi_{x^0, u}^\text{bound} (0+) \geq 0$ in the boundary case, and equality in either case implies that for each $\tau > 0$, $u_m$ converges to 0 in measure in the set $\{x_n > \tau\}$ as $m \to \infty$, and consequently $u_0 = 0$ in $\mathbb{R}^n$.

(iii),(iv): For each $\delta > 0$ and $K < +\infty$ we obtain from the Monotonicity Formula (Theorem 5.3) that in the interior case

$$
\Phi_{x, u}^\text{int} (0+) \leq \Phi_{x, u}^\text{int} (r) \leq \Phi_{x, u}^\text{int} (0+) + \frac{\delta}{2}
$$

$$
\leq \left\{ \begin{array}{ll}
\Phi_{x, u}^\text{int} (0+) + \delta, & \text{if } \Phi_{x, u}^\text{int} (0+) > -\infty, \\
-K, & \text{if } \Phi_{x, u}^\text{int} (0+) = -\infty,
\end{array} \right.
$$

and in the boundary case

$$
\Phi_{x, u}^\text{bound} (0+) \leq \Phi_{x, u}^\text{bound} (r) \leq \Phi_{x, u}^\text{bound} (0+) + \frac{\delta}{2} \leq \Phi_{x, u}^\text{bound} (0+) + \delta,
$$

if we choose for fixed $x^0$ first $r > 0$ and then $|x - x^0|$ small enough. \qed
(v) The fact that \( u_0 \) is a variational solution of (3.1) and satisfies the Monotonicity Formula in the sense indicated follows directly from the convergence assumption. The proof for the rest of the claim follows by the same argument as in (iii), (iv).

**Lemma 4.3.** Let \( u \) be a variational solution of (3.1) and suppose that

\[
|\nabla u|^2 \leq Cx_n^+ \quad \text{locally in } \Omega.
\]

Then \( \Phi^\text{int}_{x^0,u}(0+) = 0 \) implies that \( u \equiv 0 \) in some open \( n \)-dimensional ball containing \( x^0 \).

**Proof.** By the upper semicontinuity Lemma 4.2 (iii), \( \Phi^\text{int}_{x,u}(0+) \leq \epsilon \) in \( B_{\delta}(x^0) \subset \Omega \) for some \( \delta \in (0, x_n^0) \). Suppose towards a contradiction that \( u \not\equiv 0 \) in \( B_{\delta}(x^0) \). Then there exist a ball \( A \subset \{ u > 0 \} \cap B_{\delta}(x^0) \) and \( z \in \partial A \cap \{ u = 0 \} \). It follows that

\[
\Phi^\text{int}_{z,u}(0+) = z_n \lim_{r \to 0} r^{-n} \int_{B_r(z)} \chi\{u>0\} 
\geq z_n \frac{\omega_n}{2},
\]

a contradiction for sufficiently small \( \epsilon \). \( \square \)

Unfortunately, a boundary version of Lemma 4.3 stating that boundary density 0 at \( x_0 \) implies the solution being 0 in an open \( n \)-dimensional ball with center \( x_0 \), cannot be obtained in the same way. Instead we prove in the two-dimensional case the following result.

**Lemma 4.4.** Let \( n = 2 \), let \( u \) be a weak solution of (3.1) and suppose that

\[
|\nabla u|^2 \leq x_2^+ \quad \text{in } \Omega.
\]

Then \( \Phi^\text{bound}_{x^0,u}(0+) = 0 \) implies that \( u \equiv 0 \) in some open 2-dimensional ball containing \( x^0 \).

**Proof.** Suppose towards a contradiction that \( x^0 \in \partial\{ u > 0 \} \), and let us take a blow-up sequence

\[
u_m(x) := u(x^0 + r_m x)/r_m^{3/2}
\]

converging weakly in \( W^{1,2}_\text{loc}(\mathbb{R}^n) \) to a blow-up limit \( u_0 \). Lemma 4.2 (iv) shows that \( u_0 = 0 \) in \( \mathbb{R}^2 \). Consequently,

\[
0 = \Delta u_m(B_2) \geq \int_{B_2 \cap \partial_{\text{red}}\{ u_m > 0 \}} \sqrt{x_2} \, dH^1 \quad \text{as } m \to \infty. \quad (4.1)
\]

(Recall that \( \Delta u \) is a nonnegative Radon measure in \( \Omega \).) On the other hand, there is at least one connected component \( V_m \) of \( \{ u_m > 0 \} \) touching the origin and containing by the maximum principle a point \( x^m \in \partial A \), where \( A = (-1,1) \times (0,1) \). If \( \max\{x^2 : x \in V_m \cap \partial A\} \to 0 \) as \( m \to \infty \), we immediately obtain a contradiction to (4.1). If \( \max\{x^2 : x \in V_m \cap \partial A\} \to 0 \), we use the free-boundary condition as well as \( |\nabla u|^2 \leq x_2^+ \) to obtain

\[
0 = \Delta u_m(V_m \cap A) \leq \int_{V_m \cap \partial A} \sqrt{x_2} \, dH^1 - \int_{A \cap \partial_{\text{red}} V_m} \sqrt{x_2} \, dH^1.
\]
However, \( \int_{V_m \cap \partial A} \sqrt{x_2} \, dH^1 \) is the unique minimiser of \( \int_{\partial D} \sqrt{x_2} \, dH^1 \) with respect to all open sets \( D \) with \( D = V_m \) on \( \partial A \). So \( V_m \) cannot touch the origin, a contradiction. \( \square \)

**Remark 4.5.** Note that we have not really used the full information contained in the weak formulation. What we have used is the inequality \( \Delta u \geq \sqrt{x_2} H\{u > 0\} \) (which is true for any limit of the singular perturbation considered in [38]) and the fact that we can locate a non-empty portion of \( \partial_{\text{red}}\{u > 0\} \) touching \( x_0 \).

In higher dimensions it is not so clear whether *cusps* can be excluded. Of course that does not happen for Lipschitz free boundaries:

**Lemma 4.6.** Let \( u \) be a variational solution of (3.1) and suppose that
\[
|\nabla u|^2 \leq C x_n^+ \quad \text{locally in } \Omega,
\]
and that \( \{u > 0\} \) is locally a Lipschitz set. Then \( \Phi_{x_2,u}^{\text{bound}}(0+) = 0 \) implies that \( u \equiv 0 \) in some open \( n \)-dimensional ball containing \( x_0 \).

**Proof.** This is an immediate consequence of Lemma 4.2 (ii) and the Lipschitz continuity. \( \square \)

**Proposition 4.7 (Two-dimensional Case).** Let \( n = 2 \), let \( u \) be a variational solution of (3.1), and suppose that
\[
|\nabla u|^2 \leq C x_2^+ \quad \text{locally in } \Omega.
\]
Let \( x_0 \in \Omega \) be such that \( u(x_0) = 0 \), and suppose that
\[
r^{-1} \int_{B_r(x_0)} |\nabla \chi_{\{u > 0\}}| \leq C_0
\]
for all \( r > 0 \) such that \( B_r(x_0) \subset \subset \Omega \) in the interior case, and that
\[
r^{-3/2} \int_{B_r(x_0)} \sqrt{x_2} |\nabla \chi_{\{u > 0\}}| \leq C_0
\]
for all \( r > 0 \) such that \( B_r(x_0) \subset \subset \Omega \) in the boundary case.

(i) Interior Case \( x_0^2 > 0 \): The only possible blow-up limits are
\[
u_0(x) = \sqrt{x_0^2} \max(x \cdot e, 0) \quad \text{and} \quad u_0(x) = \gamma |x \cdot e|,
\]
where \( e \) is a unit vector and \( \gamma \) is a nonnegative constant. In the case \( u_0(x) = \sqrt{x_0^2} \max(x \cdot e, 0) \) the corresponding density value is \( \omega_2/2 \), in the case \( u_0(x) = \gamma |x \cdot e| \) with \( \gamma > 0 \) the density is \( \omega_2 \), while in the case \( u_0 = 0 \) the density may be either 0 or \( \omega_2 \).

(ii) Boundary Case \( x_0^2 = 0 \): The only possible blow-up limits are
\[
u_0(\rho, \theta) = \frac{\sqrt{2}}{3} \rho^{3/2} \max(3(\theta - \pi/2)/2, 0),
\]
with corresponding density
\[ \int_{B_1} x_2^+ \chi_{\{ \cos(3(\theta - \pi/2)/2) > 0 \}} , \]
and \( u_0(x) = 0 \), with possible values of the density
\[ \int_{B_1} x_2^+ \text{ and } 0. \]

Proof. Consider a blow-up sequence \( u_m \) as in Lemma 4.1 where \( r_m \to 0 \), with blow-up limit \( u_0 \). Because of the strong convergence of \( u_m \) to \( u_0 \) in \( W^{1,2}_{loc}(\mathbb{R}^2) \) and the compact embedding from \( BV \) into \( L^1 \), \( u_0 \) is a homogeneous solution of
\[ 0 = \int_{\mathbb{R}^2} (|\nabla u_0|^2 \text{div } \phi - 2\nabla u_0 D\phi \nabla u_0) + x_2^0 \int_{\mathbb{R}^2} \chi_0 \text{div } \phi \quad (4.2) \]
for any \( \phi \in C^1_c(\mathbb{R}^2; \mathbb{R}^2) \) in the interior case, and of
\[ 0 = \int_{\mathbb{R}^2} (|\nabla u_0|^2 \text{div } \phi - 2\nabla u_0 D\phi \nabla u_0) + \int_{\mathbb{R}^2} (x_2 \chi_0 \text{div } \phi + \chi_0 \phi_2) \quad (4.3) \]
for any \( \phi \in C^1_c(\mathbb{R}^2; \mathbb{R}^2) \) in the boundary case, where \( \chi_0 \) is the strong \( L^1_{loc} \)-limit of \( \chi_{\{ u_m > 0 \}} \) along a subsequence. The values of the function \( \chi_0 \) are almost everywhere in \( \{0, 1\} \), and the locally uniform convergence of \( u_m \) to \( u_0 \) implies that \( \chi_0 = 1 \) in \( \{u_0 > 0\} \). The homogeneity of \( u_0 \) and its harmonicity in \( \{u_0 > 0\} \) show that each connected component of \( \{u_0 > 0\} \) is a half-plane passing through the origin in the interior case, and a cone with vertex at the origin and of opening angle 120° in the boundary case. Also, \( (4.2) \) and \( (4.3) \) imply \( \chi_0 \) is constant in the connected set \( \{u_0 = 0\}^c \).

Consider first the case when \( \{u_0 > 0\} \) has exactly one connected component. Let \( z \) be an arbitrary point in \( \partial \{u_0 = 0\} \setminus \{0\} \). Note that the normal to \( \partial \{u_0 = 0\} \) has the constant value \( \nu(z) \) in \( B_{\delta}(z) \) for some \( \delta > 0 \). Plugging in \( \phi(x) := \eta(x) \nu(z) \) into \( (4.2) \) and \( (4.3) \), where \( \eta \in C^1_c(\mathbb{R}^2;\mathbb{R}^2) \) is arbitrary, and integrating by parts, it follows that
\[ 0 = \int_{\partial \{u_0 > 0\}} (-|\nabla u_0|^2 + x_2^0(1 - \bar{\chi}_0)) \eta \, d\mathcal{H}^1 \quad (4.4) \]
in the interior case and that
\[ 0 = \int_{\partial \{u_0 > 0\}} (-|\nabla u_0|^2 + x_2(1 - \bar{\chi}_0)) \eta \, d\mathcal{H}^1 \quad (4.5) \]
in the boundary case. Here \( \bar{\chi}_0 \) denotes the constant value of \( \chi_0 \) in \( \{u_0 = 0\}^c \). Note that by Hopf’s principle, \( \nabla u_0 \cdot \nu \neq 0 \) on \( B_{\delta}(z) \cap \partial \{u_0 > 0\} \). In both interior and boundary case it follows therefore that \( \bar{\chi}_0 \neq 1 \), and hence necessarily \( \bar{\chi}_0 = 0 \). We deduce from \( (4.3) \) and \( (4.5) \) that \( |\nabla u_0|^2 = x_2^0 \) on \( \partial \{u_0 > 0\} \) in the interior case and that \( |\nabla u_0|^2 = x_2 \) on \( \partial \{u_0 > 0\} \) in the boundary case. Computing the ODE solution \( u_0 \) on \( \partial B_1 \) yields the statement of the Proposition in the case under consideration.

In the case \( u_0 = 0 \), \( (4.2) \) and \( (4.3) \) show that \( \chi_0 \) is constant in \( \mathbb{R}^2 \). Its value may be either 0 or 1.
Last, consider the situation when, in the interior case, the set \( \{ u_0 > 0 \} \) has two connected components. The argument for (4.4) now yields that the constant values of \( |\nabla u_0|^2 \) on either side of \( \partial \{ u_0 > 0 \} \) are equal. This yields the statement of the Proposition.

\[ \square \]

5. Partial regularity of non-degenerate solutions

Definition 5.1 (Stagnation Points). Let \( u \) be a variational solution of (3.1). We call \( S_u := \{ x \in \Omega : x_n = 0 \text{ and } x \in \partial \{ u > 0 \} \} \) the set of stagnation points.

Definition 5.2 (Non-degeneracy, Density Condition). Let \( u \) be a variational solution of (3.1).

(i) We say that a point \( x_0^0 \in \Omega \cap \partial \{ u > 0 \} \cap \{ x_n = 0 \} \) satisfies property (\( N \)) if

\[
\liminf_{r \to 0} r^{-n-3} \int_{B_r(x^0)} u^2 > 0.
\]

Moreover we define for each \( \kappa > 0 \) and \( \varsigma > 0 \) the set

\[
N_{\varsigma,\kappa}^u := \{ x^0 \in \Omega \cap \partial \{ u > 0 \} \cap \{ x_n = 0 \} : r^{-n-3} \int_{B_r(x^0)} u^2 \geq \kappa \text{ for } r \in (0,\varsigma] \}.
\]

(ii) We say that a point \( x^0 \in \Omega \cap \partial \{ u > 0 \} \cap \{ x_n = 0 \} \) satisfies property (\( D \)) if

\[
0 < \liminf_{r \to 0} r^{-n-1} \int_{B_r(x^0)} x_n^+ \chi\{u>0\} \\
\leq \limsup_{r \to 0} r^{-n-1} \int_{B_r(x^0)} x_n^+ \chi\{u>0\} \\
< \int_{B_1} x_n^+.
\]

Note that \( \bigcup_{\varsigma,\kappa} N_{\varsigma,\kappa}^u \) is the set of all points satisfying property (\( N \)).

Lemma 5.3. Let \( u \) be a variational solution of (3.1) and suppose that

\[
|\nabla u|^2 \leq C x_n^+ \text{ locally in } \Omega,
\]

and that

\[
r^{1/2-n} \int_{B_r(y)} \sqrt{x_n} |\nabla \chi\{u>0\}| \leq C_0
\]

for all \( B_r(y) \subset \subset \Omega \) such that \( y_n = 0 \). Then properties (\( N \)) and (\( D \)) are equivalent.

Proof. (\( D \) \( \Rightarrow \) (\( N \))): Consider a blow-up limit \( u_0 \) of the sequence

\[
u_m(x) := u(x^0 + r_m x)/r_m^{3/2},
\]
where \( r_m \to 0 \), and suppose towards a contradiction that \( u_0 = 0 \). Passing to the limit in the domain variation equation we obtain

\[
0 = \int_{\mathbb{R}^n} \left( |\nabla u_0|^2 \text{div } \phi - 2\nabla u_0 D\phi \nabla u_0 + x_n \chi_0 \text{div } \phi + \chi_0 \phi_n \right)
\]

for any \( \phi \in C_0^1(\mathbb{R}^n; \mathbb{R}^n) \), where \( \chi_0 \) is the limit of \( \chi_{\{u_m > 0\}} \) with respect to a subsequence. This implies that \( \chi_0 \) is a constant function. On the other hand, the condition on \( |\nabla \chi_{\{u > 0\}}| \) implies that the values of \( \chi_0 \) are almost everywhere in \( \{0, 1\} \), and then condition (D) shows that the function \( \chi_0 \) is not constant, a contradiction.

\[\text{(N) } \Rightarrow \text{(D)}: \text{ The proof draws on } [38, \text{ Proof of Proposition 9.1}]. \]

Let us again consider a blow-up limit \( u_0 \) of the sequence \( u_m(x) := u(x_0 + r_m x) / r_m^{3/2} \), and suppose towards a contradiction that \( \chi_0 := \lim_{m \to \infty} \chi_{\{u_m > 0\}} \equiv 1 \). By the Monotonicity Formula (which holds for \( u_0 \) with \( \chi_{\{u_0 > 0\}} \) replaced by \( \chi_0 \)) and the growth estimate we obtain for each point \( x \) such that \( x_n = 0 \),

\[
0 \leftarrow \Phi_{x, u_0}^\text{bound}(\sigma) - \Phi_{0, u_0}^\text{bound}(\sigma)
= \Phi_{x, u_0}^\text{bound}(\sigma) - \Phi_{0, u_0}^\text{bound}(0+)
= \Phi_{x, u_0}^\text{bound}(\sigma) - \Phi_{x, u_0}^\text{bound}(0+)
= \int_0^\sigma r^{-n-1} \int_{\partial B_r(x)} 2 \left( \nabla u \cdot \nu - \frac{3 u}{2 r} \right)^2 dH^{n-1} dr
\]

as \( \sigma \to +\infty \). But this means that \( u_0 \) is homogeneous of degree 3/2 with respect to each point \( x \) such that \( x_n = 0 \). It follows that \( u_0 \) depends only on the \( x_n \)-variable. Thus \( u_0(x) = \alpha (x_n^+)^{3/2} \) for some \( \alpha \geq 0 \), a contradiction to the definition of variational solution unless \( \alpha = 0 \). \( \Box \)

**Proposition 5.4 (Two-dimensional Case).** Let \( n = 2 \), let \( u \) be a variational solution of \( (3.1) \), suppose that \( |\nabla u| \leq C x_2^+ \) locally in \( \Omega \), and that

\[
r^{-3/2} \int_{B_r(y)} \sqrt{x_2} |\nabla \chi_{\{u > 0\}}| \leq C_0
\]

for all \( B_r(y) \subset \subset \Omega \) such that \( y_n = 0 \). At each non-degenerate stagnation point \( x_0 \), the density \( \Phi_{x_0, u}^\text{bound}(0+) \) has the value

\[
\int_{B_1} x_2^+ \chi_{\{x_2 \cos(3(\theta - \pi/2)/2) > 0\}}
\]

and

\[
\frac{u(x_0 + rx)}{r^{3/2}} \to \frac{\sqrt{2}}{3} \rho^{3/2} \max(\cos(3(\theta - \pi/2)/2), 0) \quad \text{as } r \searrow 0,
\]
strongly in \( W_{\text{loc}}^{1,2}(\mathbb{R}^2) \) and locally uniformly on \( \mathbb{R}^2 \), where \( x = (\rho \cos \theta, \rho \sin \theta) \). Moreover,

\[
\mathcal{L}^2(B_1 \cap \{x : u(x^0 + r x) > 0\} \triangle \{\cos(3(\theta - \pi/2)/2) > 0\}) \to 0 \quad \text{as} \ r \searrow 0,
\]

and, for each \( \delta > 0 \),

\[
r^{-3/2} \Delta u((x^0 + B_r) \cap \{\cos(3(\theta - \pi/2)/2) > \delta\} \cup \{\cos(3(\theta - \pi/2)/2) < -\delta\}) \to 0 \quad \text{as} \ r \searrow 0.
\]

(Recall that \( \Delta u \) is a nonnegative Radon measure in \( \Omega \).)

**Proof.** The value of the density and the uniqueness of the blow-up limit follow directly from Proposition 4.7 (ii) and the non-degeneracy assumption.

Let \( \mathbf{r} \in \mathbb{R}^2 \) be a non-degenerate point. Then \( u \) is harmonic in \( \Omega \) and, for each \( \mathbf{B} \) in some open neighborhood, \( x \) and that

\[
\lim_{\mathbf{r} \to x} u(\mathbf{B} \setminus x) = \lim_{\mathbf{r} \to x} u(\mathbf{B}) - u(x).
\]

By the proof of Proposition 4.7, \( \chi_{\{u > 0\}} \) converges strongly in \( L^1(B_1) \) to \( \chi_{\{u_m > 0\}} \) along a subsequence. Since this is true for all sequences \( \mathbf{r} \searrow 0 \), it follows that

\[
\chi_{\{u : u(x^0 + r x) > 0\}} \to \chi_{\{u_0 > 0\}} \quad \text{strongly in} \ L^1(B_1) \quad \text{as} \ r \searrow 0,
\]

which is exactly the first measure estimate. The convergence of \( u_m \) to \( u_0 \) implies the weak convergence of the sequence of nonnegative Radon measures \( \Delta u_m \) to \( \Delta u_0 \). Since \( u_0 \) is harmonic in \( \{\cos(3(\theta - \pi/2)/2) > \delta/2\} \cup \{\cos(3(\theta - \pi/2)/2) < -\delta/2\} \), it follows that

\[
\Delta u_m(B_1 \cap \{\cos(3(\theta - \pi/2)/2) > \delta\} \cup \{\cos(3(\theta - \pi/2)/2) < -\delta\}) \to 0
\]

as \( m \to \infty \). Since this is true for all sequences \( \mathbf{r} \searrow 0 \), the second measure estimate follows. \( \square \)

**Proposition 5.5** (Partial regularity in two dimensions). Let \( n = 2 \), let \( u \) be a variational solution of (3.1), and suppose that

\[
|\nabla u|^2 \leq C x_2^+ \quad \text{locally in} \ \Omega,
\]

and that

\[
r^{-3/2} \int_{B_r(y)} \sqrt{x_2} |\nabla \chi_{\{u > 0\}}| \leq C_0
\]

for all \( B_r(y) \subset \subset \Omega \) such that \( y_2 = 0 \). Let \( x^0 \in S^n \) be a non-degenerate point. Then in some open neighborhood, \( x^0 \) is the only non-degenerate stagnation point.

**Proof.** Suppose towards a contradiction that there exists a sequence \( x^m \) of non-degenerate points converging to \( x^0 \), with \( x^m \neq x_0 \) for all \( m \). Choosing \( \mathbf{r}_m := |x^m - x^0| \), there is no loss of generality in assuming that the sequence \( (x^m - x^0)/\mathbf{r}_m \) is constant, with value \( z \in \{(-1,0), (1,0)\} \). Consider the blow-up sequence

\[
u_m(x) = u(x^0 + r_m x)/r_m^{3/2}.
\]
Since $x^m$ is a non-degenerate point for $u$, it follows that $z$ is a non-degenerate point for $u_m$, and therefore Proposition 4.4 shows that

$$
\Phi^{\text{bound}}_{z,u,m}(0+) = \int_{B_1} x_n^+ \chi_{\{\cos(3(\theta - \pi/2)/2) > 0\}}.
$$

By Lemma 4.1 (v) and the proof of Proposition 4.7(ii), the sequence $u_m$ converges strongly in $W^{1,2}_{\text{loc}}(\mathbb{R}^2)$ to the homogeneous solution

$$
u_0(\rho, \theta) = \frac{\sqrt{2}}{3} \rho^{3/2} \max(\cos(3(\theta - \pi/2)/2), 0),
$$

where $x = (\rho \cos \theta, \rho \sin \theta)$, while $\chi_{\{u_m > 0\}}$ converges strongly in $L^1_{\text{loc}}(\mathbb{R}^2)$ to $\chi_{\{u_0 > 0\}}$.

It follows from Lemma 4.2 (v) that

$$
\Phi^{\text{bound}}_{z,u^0}(0+) \geq \limsup_{m \to \infty} \Phi^{\text{bound}}_{z,u,m}(0+) = \int_{B_1} x_n^+ \chi_{\{\cos(3(\theta - \pi/2)/2) > 0\}}
$$

contradicting the fact that

$$
\Phi^{\text{bound}}_{z,u^0}(0+) = 0.
$$

□

**Remark 5.6.** It follows that in two dimensions $S^u$ can be decomposed into a countable set of “Stokes points” with the asymptotics as in Proposition 5.4 accumulating (if at all) only at “degenerate stagnation points”, and a set of “degenerate stagnation points” which will be analyzed in the following sections.

The following Lemma will be used in order to prove the partial regularity result Proposition 5.8.

**Lemma 5.7.** Let $u$ be a variational solution of (3.1) and suppose that

$$
|\nabla u|^2 \leq C x_n^+ \quad \text{locally in } \Omega,
$$

and that

$$
r^{1/2-n} \int_{B_r(y)} \sqrt{x_n} |\nabla \chi_{\{u > 0\}}| \leq C_0
$$

for all $B_r(y) \subset \subset \Omega$ such that $y_n = 0$. Suppose that $x^0 \in S^u$ and let $u_0$ be a blow-up limit of

$$
u_m(x) := u(x^0 + r_m x)/r_m^{3/2}.
$$

Then for each compact set $K \subset \mathbb{R}^n$ and each open set $U \supset K \cap N^u_{\varsigma,\kappa}$ there exists $m_0 < \infty$ such that $N^u_{\varsigma,\kappa} \cap K \subset U$ for $m \geq m_0$.

**Proof.** Suppose towards a contradiction that $N^u_{\varsigma,\kappa} \cap (K \setminus U)$ contains a sequence $x^m$ converging to $\bar{x}$ as $m \to \infty$. Then $\bar{x}_n = 0$, and by the locally uniform Lipschitz continuity of $u_m$, $\bar{x} \in \{u_0 = 0\} \cap (K \setminus U)$. But this contradicts the assumption $U \supset K \cap N^u_{\varsigma,\kappa}$ by the uniform convergence of $u_m$. □
Proposition 5.8 (Partial regularity in higher dimensions). Let $u$ be a variational solution of (3.1) and suppose that

$$|\nabla u|^2 \leq C x_n^+ \text{ locally in } \Omega,$$

and that

$$r^{1/2-n} \int_{B_r(y)} \sqrt{x_n} |\nabla \chi_{\{u>0\}}| \leq C_0$$

for all $B_r(y) \subset \subset \Omega$ such that $y_n = 0$. Then the Hausdorff dimension of the set $\bigcup_{\varsigma,\kappa} N_{\varsigma,\kappa}^u$ of all non-degenerate points is less or equal than $n - 2$.

The proof uses standard tools of geometric measure theory and will be done in the Appendix.

Remark 5.9. It follows that the Hausdorff dimension of the set of non-degenerate stagnation points is less or equal than $n - 2$. From Lemma 5.3 we infer that the set of stagnation points satisfying the density condition also has dimension at most $n - 2$.

6. Degenerate Points

Definition 6.1. Let $u$ be a variational solution of (3.1). We define

$$\Sigma^u := \{x^0 \in S^u : \Phi^{\text{bound}}_{x^0,u}(0+) = \int_{B_1} x_n^+ \}.$$

Remark 6.2. The set $\Sigma^u$ is closed, as a consequence of the upper semicontinuity Lemma 4.2 (iv).

Remark 6.3. In the case of two dimensions and a weak solution $u$, we infer from Lemma 5.3 and Lemma 4.4 that the set $S^u \setminus \Sigma^u$ equals the set of non-degenerate stagnation points and is according to Proposition 5.4 a finite or countable set.

The following Lemma is drawn from [38, Theorem 11.1].

Lemma 6.4. Let $u$ be a variational solution of (3.1), let $x^0 \in \Sigma^u$, and let $\delta := \text{dist}(x^0, \partial \Omega)/2$. Then:

(i) The mean frequency satisfies, for all $r \in (0, \delta)$,

$$r \int_{B_r(x^0)} \frac{|\nabla u|^2}{u^2} d\mathcal{H}^{n-1} - \frac{3}{2} \geq r \int_{\partial B_r(x^0)} x_n^+ (1 - \chi_{\{u>0\}}) d\mathcal{H}^{n-1} \geq 0.$$

(ii) The function $r \mapsto r^{-n-2} \int_{\partial B_r(x^0)} u^2 d\mathcal{H}^{n-1}$ is non-decreasing on $(0, \delta)$ and has the right limit 0 at 0.

(iii) The function $r \mapsto r^{-n-2} \int_{B_r(x^0)} x_n^+ (1 - \chi_{\{u>0\}})$ is integrable on $(0, \delta)$.

Proof. (i): The inequality

$$\Phi^{\text{bound}}_{x^0,u}(0+) \leq \Phi^{\text{bound}}_{x^0,u}(r)$$
and the right-hand side is clearly nonnegative.

(ii): Plugging in $\alpha := -n - 2$ into (3.2) and using (3.4), it follows that

$$
\frac{d}{dr} \left( r^{-n-2} \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1} \right) = 2 \left( r^{-n-1} \int_{B_r(x^0)} |\nabla u|^2 - \frac{3}{2} r^{-n-2} \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1} \right) \\
\geq 2r^{-n-2} \int_{B_r(x^0)} x_n^+ (1 - \chi_{\{u > 0\}}).$$

Hence $r \mapsto r^{-n-2} \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1}$ is non-decreasing on $(0, \delta)$. Using Lemma 5.3 we obtain that its right limit at 0 is 0.

(iii): The above inequality implies that the function $r \mapsto r^{-n-2} \int_{B_r(x^0)} x_n^+ (1 - \chi_{\{u > 0\}})$ is in $L^1((0, \delta))$. \qed

7. The Frequency Formula

Theorem 7.1 (Frequency Formula). Let $u$ be a variational solution of (3.1), let $x^0$ be a point of the closed set $\Sigma^u$, and let $\delta := \text{dist}(x^0, \partial \Omega)/2$. The function

$$F_{x^0,u}(r) := r \int_{B_r(x^0)} \left( |\nabla u|^2 + x_n^+ (\chi_{\{u > 0\}} - 1) \right) \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1}$$

satisfies for a.e. $r \in (0, \delta)$ the identity

$$
\frac{d}{dr} F_{x^0,u}(r) = \frac{2}{r} \left( \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1} \right)^{-2} \left[ \int_{\partial B_r(x^0)} (\nabla u \cdot (x - x^0))^2 \, d\mathcal{H}^{n-1} \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1} \right. \\
- \left. \left( \int_{\partial B_r(x^0)} u \nabla u \cdot (x - x^0) \, d\mathcal{H}^{n-1} \right)^2 \right] \\
+ 2 \frac{\int_{B_r(x^0)} x_n^+ (1 - \chi_{\{u > 0\}})}{\int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1}} \left( \frac{\int_{B_r(x^0)} |\nabla u|^2}{\int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1}} - \frac{3}{2} \right).
$$

The function $r \mapsto F_{x^0,u}(r)$ is non-decreasing on $(0, \delta)$, and there exists

$$F_{x^0,u}(0^+) := \lim_{r \to 0} F_{x^0,u}(r) \in [3/2, \infty).$$
Remark 7.2. This formula is based on an analogous formula in the interior case derived by the second author for a more general class of semilinear elliptic equations ([35]). The root is the classical frequency formula of F. Almgren for $Q$-valued harmonic functions [1]. Almgren’s formula has subsequently been extended to various perturbations (see [14] for a recent extension). Note however that while our formula may look like a perturbation of the “linear” formula for $Q$-valued harmonic functions, it is in fact a truly nonlinear formula. This fact will be become more obvious in the paper [35] for more general semilinearities.

Proof. Assuming the validity of the claimed identity, the monotonicity of $F_{x^0,u}$ follows from combining the Cauchy-Schwarz inequality

$$\int_{\partial B_r(x^0)} (\nabla u \cdot (x - x^0))^2 \, dH^{n-1} \geq \left( \int_{\partial B_r(x^0)} u \nabla u \cdot (x - x^0) \, dH^{n-1} \right)^2$$

with Lemma 6.4 (i). The same Lemma also shows that $r \mapsto F_{x^0,u}(r)$ is bounded below by $3/2$. Thus it remains to prove the claimed identity.

Note that

$$F_{x^0,u}(r) = \frac{U(r) - \int_{B_1} x^+_n}{W(r)}$$

where $U := U_{\text{bound}}$ and $W := W_{\text{bound}}$ are the functions in the proof of Theorem 3.5. Hence

$$\frac{d}{dr} F_{x^0,u}(r) = \frac{U'(r)W(r) - W'(r)(U(r) - r^{-n-1} \int_{B_r(x^0)} x^+_n)}{W^2(r)}.$$
Using (3.4), we obtain

\[
\frac{d}{dr} F_{x^0, u}(r) = \left( \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1} \right)^{-2} \left[ 2r \int_{\partial B_r(x^0)} (\nabla u \cdot \nu)^2 \, d\mathcal{H}^{n-1} \right. \\
\left. - 2r \left( \int_{\partial B_r(x^0)} u \nabla u \cdot \nu \, d\mathcal{H}^{n-1} \right)^2 \right] \\
+ \left( \int_{B_r(x^0)} x_n^+ \left( 1 - \chi\{u > 0\} \right) \right) \left( 2r \int_{\partial B_r(x^0)} u \nabla u \cdot \nu \, d\mathcal{H}^{n-1} - 3\int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1} \right)
\]

which, upon rearranging and using again (3.4) (this time in the reverse direction), gives the required result. □

**Corollary 7.3.** Let \( u \) be a variational solution of (3.1), let \( x^0 \) be a point of the closed set \( \Sigma^u \), and let \( \delta := \text{dist}(x, \partial \Omega)/2 \). Let us consider, for \( r \in (0, \delta) \), the functions

\[
D(r) := r \int_{\partial B_r(x^0)} |\nabla u|^2 u^2 \, d\mathcal{H}^{n-1}
\]

and

\[
V(r) := r \int_{B_r(x^0)} x_n^+ \left( 1 - \chi\{u > 0\} \right) u^2 \, d\mathcal{H}^{n-1}
\]

so that \( F_{x^0, u}(r) = D(r) - V(r) \).

(i) For every \( r \in (0, \delta) \), the following inequalities hold:

\[
(D - V)'(r) \geq \frac{2}{r} V(r) (D(r) - 3/2) \geq \frac{2}{r} V^2(r).
\]

(ii) The function \( r \mapsto \frac{2}{r} V^2(r) \) is integrable on \((0, \delta)\).

**Proof of Corollary 7.3.** The inequalities follow from Lemma 6.4 and Theorem 7.1. The integrability of \( r \mapsto \frac{2}{r} V^2(r) \) is a consequence of the inequalities. □

**Corollary 7.4 (Density).** Let \( u \) be a variational solution of (3.1). The function

\[
x \mapsto F_{x, u}(0+)
\]

is upper semicontinuous on the closed set \( \Sigma^u \).

**Proof of Corollary 7.4.** For each \( \delta > 0 \), we have that

\[
F_{x, u}(0+) \leq F_{x, u}(r) \leq F_{x^0, u}(r) + \frac{\delta}{2} \leq F_{x^0, u}(0+) + \delta,
\]

if we choose for fixed \( x^0 \in \Sigma^u \) first \( r > 0 \) and then \( |x - x^0| \) small enough. □
The next result is an improvement of Lemma 6.4 at those points of $\Sigma^u$ at which the frequency is greater than $3/2$.

**Lemma 7.5.** Let $u$ be a variational solution of (8.1), let $x^0 \in \Sigma^u$, and let $\delta := \text{dist}(x^0, \partial\Omega)/2$. Suppose that $F_{x^0,u}(0+) > 3/2$, and let us denote $\gamma := F_{x^0,u}(0+)$. Then:

(i) For all $r \in (0, \delta)$,
\[
\frac{\int_{B_r(x^0)} |\nabla u|^2}{\int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1}} - \gamma \geq \frac{\int_{B_r(x^0)} x^+_n (1 - \chi_{(u>0)})}{\int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1}} \geq 0.
\]

(ii) The function $r \mapsto r^{1-n-2\gamma} \int_{\partial B_r(x^0)} u^2 \, d\mathcal{H}^{n-1}$ is non-decreasing on $(0, \delta)$.

(iii) The function $r \mapsto r^{1-n-2\gamma} \int_{B_r(x^0)} x^+_n (1 - \chi_{(u>0)})$ is integrable on $(0, \delta)$.

(iv) For each $\beta \in [0, \gamma)$,
\[
\frac{u(x^0 + rx)}{r^\beta} \to 0 \quad \text{strongly in } L^2_{\text{loc}}(\mathbb{R}^n) \quad \text{as } r \searrow 0.
\]

**Proof.** Part (i) follows from the fact that $F_{x^0,u}(r) \geq \gamma$ for all $r \in (0, \delta)$. Parts (ii) and (iii) follow by the same arguments as for the corresponding statements in Lemma 6.4. It is a consequence of part (ii) that $r \mapsto r^{-n-2\gamma} \int_{B_r(x^0)} u^2$ is non-decreasing on $(0, \delta)$, and therefore, for each $\beta \in [0, \gamma)$,
\[
r^{-n-2\beta} \int_{B_r(x^0)} u^2 \to 0 \quad \text{as } r \searrow 0.
\]

This implies part (iv) of the Lemma.

\[
\square
\]

8. Blow-up limits

The Frequency Formula allows passing to blow-up limits.

**Proposition 8.1.** Let $u$ be a variational solution of (8.1), and let $x^0 \in \Sigma^u$. Then:

(i) There exist $\lim_{r \searrow 0} V(r) = 0$ and $\lim_{r \searrow 0} D(r) = F_{x^0,u}(0+)$. 

(ii) For any sequence $r_m \searrow 0$ as $m \to \infty$, the sequence
\[
v_m(x) := \frac{u(x^0 + r_mx)}{\sqrt{r_m^{1-u} \int_{\partial B_{r_m}(x^0)} u^2 \, d\mathcal{H}^{n-1}}} \tag{8.1}
\]
is bounded in $W^{1,2}(B_1)$.

(iii) For each sequence $r_m \searrow 0$ as $m \to \infty$ such that the sequence $v_m$ in (8.1) converges weakly in $W^{1,2}(B_1)$ to a blow-up limit $v_0$, the function $v_0$ is continuous and homogeneous of degree $F_{x^0,u}(0+)$ in $B_1$, and satisfies $v_0 \geq 0$ in $B_1$ and $v_0 \equiv 0$ in $B_1 \cap \{x_2 \leq 0\}$ and $\int_{\partial B_1} v_0^2 \, d\mathcal{H}^{n-1} = 1$.

**Proof.** The key step in the proof is the statement (8.1), which we prove first. We start by writing the right-hand side of the Frequency Formula in a more convenient
form, using a simple algebraic identity. For any real inner-product space \((H, \langle \cdot, \cdot \rangle)\) with norm \(|||\cdot|||\), any vectors \(u, v\) and any scalar \(\alpha\), the following holds:

\[
\frac{1}{||u||^4} \left[ ||v||^2 ||u||^2 - \langle v, u \rangle^2 \right] = \left\| \frac{v}{||u||} - \frac{\langle v, u \rangle}{||u||^2} u \right\|^2 = \left\| \frac{v}{||u||} - \frac{\langle v, u \rangle}{||u||^2} u + \alpha \frac{u}{||u||} \right\|^2 - \alpha^2,
\]

where we have used a cancellation due to orthogonality. Using the notation introduced in Corollary 7.3, we apply the above identity in the space \(L^2(\partial B_r(x^0))\), with \(u := u, v := r(\nabla u \cdot \nu)\) and \(\alpha := V(r)\), after also taking into account (3.3) in the form

\[
\frac{\langle v, u \rangle}{||u||^2} = D(r),
\]

to obtain from the Frequency Formula that

\[
\frac{d}{dr} F_{x^0,u}(r) = \frac{2}{r} \int_{\partial B_r(x^0)} \left[ \frac{r(\nabla u \cdot \nu)}{\left( \int_{\partial B_r(x^0)} u^2 d\mathcal{H}^{n-1} \right)^{1/2}} - F_{x^0,u}(r) \frac{u}{\left( \int_{\partial B_r(x^0)} u^2 d\mathcal{H}^{n-1} \right)^{1/2}} \right]^2 d\mathcal{H}^{n-1} + \frac{2}{r} V^2(r) + \frac{2}{r} V(r)(F_{x^0,u}(r) - 3/2).
\]

This formula can be rewritten as

\[
\frac{d}{dr} F_{x^0,u}(r) = \frac{2}{r} \int_{\partial B_r(x^0)} \left[ \frac{r(\nabla u \cdot \nu)}{\left( \int_{\partial B_r(x^0)} u^2 d\mathcal{H}^{n-1} \right)^{1/2}} - F_{x^0,u}(r) \frac{u}{\left( \int_{\partial B_r(x^0)} u^2 d\mathcal{H}^{n-1} \right)^{1/2}} \right]^2 d\mathcal{H}^{n-1} + \frac{2}{r} V(r)(F_{x^0,u}(r) - 3/2).
\]

Since \(F_{x^0,u}(r) \geq 3/2\) for all \(r \in (0, \delta)\), we obtain therefore that for all \(0 < \theta < \sigma < \delta\),

\[
\int_\theta^\sigma \frac{2}{r} \int_{\partial B_r(x^0)} \left[ \frac{r(\nabla u \cdot \nu)}{\left( \int_{\partial B_r(x^0)} u^2 d\mathcal{H}^{n-1} \right)^{1/2}} - F_{x^0,u}(r) \frac{u}{\left( \int_{\partial B_r(x^0)} u^2 d\mathcal{H}^{n-1} \right)^{1/2}} \right]^2 d\mathcal{H}^{n-1} dr \leq F_{x^0,u}(\sigma) - F_{x^0,u}(\theta).
\]

Let us consider now an arbitrary sequence \(r_m\) such that \(r_m \searrow 0\) as \(m \to \infty\), and let \(v_m\) be the sequence defined in (8.1). It follows by scaling from (8.3) that, for every \(m\) such that \(r_m \delta < 1\) and for every \(0 < \theta < \sigma < 1\),

\[
\int_\theta^\sigma \frac{2}{r} \int_{\partial B_r} \left[ \frac{r(\nabla v_m \cdot \nu)}{\left( \int_{\partial B_r} v_m^2 d\mathcal{H}^{n-1} \right)^{1/2}} - F_{x^0,u}(r) \frac{v_m}{\left( \int_{\partial B_r} v_m^2 d\mathcal{H}^{n-1} \right)^{1/2}} \right]^2 d\mathcal{H}^{n-1} dr \leq F_{x^0,u}(r_m \sigma) - F_{x^0,u}(r_m \theta) \to 0 \quad \text{as} \quad m \to \infty,
\]
since $F_{x^0, u}$ has a finite limit at 0. The above implies that

$$
\int_0^a \frac{2}{r} \int_{\partial B_r} \left[ \frac{r(\nabla v_m \cdot \nu)}{\left( \int_{\partial B_r} v_m^2 d\mathcal{H}^{n-1} \right)^{1/2}} - F_{x^0, u}(0+) \frac{v_m}{\left( \int_{\partial B_r} v_m^2 d\mathcal{H}^{n-1} \right)^{1/2}} \right]^2 d\mathcal{H}^{n-1} dr
\to 0 \quad \text{as } m \to \infty.
$$

(8.4)

Now note that, for every $r \in (\varrho, \sigma) \subset (0, 1)$ and all $m$ as before, it follows by using Lemma 6.4 that

$$
\int_{\partial B_r} v_m^2 d\mathcal{H}^{n-1} = \frac{\int_{\partial B_{m/r}(x_0)} u^2 d\mathcal{H}^{n-1}}{\int_{\partial B_{m/r}(x_0)} u^2 d\mathcal{H}^{n-1}} \leq r^{n+2} \leq 1.
$$

Therefore 8.4 implies that

$$
\int_{B_{s/m} \setminus B_{s}} |x|^{-n-3} [\nabla v_m(x) \cdot x - F_{x^0, u}(0+)v_m(x)]^2 dx \to 0 \quad \text{as } m \to \infty. \tag{8.5}
$$

We can now prove all parts of the Proposition.

(i) Suppose towards a contradiction that (i) is not true. Let $s_m \to 0$ be a sequence such that $V(s_m)$ is bounded away from 0. From the integrability of $r \mapsto \frac{2}{r} V^2(r)$ we obtain that

$$
\min_{r \in [s_m, 2s_m]} V(r) \to 0 \quad \text{as } m \to \infty.
$$

Let $t_m \in [s_m, 2s_m]$ be such that $V(t_m) \to 0$ as $m \to \infty$. For the choice $r_m := t_m$ for each $m$, the sequence $v_m$ given by 8.1 satisfies 8.3. The fact that $V(r_m) \to 0$ implies that $D(r_m)$ is bounded, and hence $v_m$ is bounded in $W^{1,2}(B_1)$. Let $v_0$ be any weak limit of $v_m$ along a subsequence. Note that $v_0$ has norm 1 on $L^2(\partial B_1)$, since this is true for $v_m$ for all $m$. It follows from 8.3 that $v_0$ is homogeneous of degree $F_{x^0, u}(0+)$. Note that, by using Lemma 6.3 (ii),

$$
V(s_m) = \frac{s_m^{-n-1} \int_{B_{s_m}(x_0)} \chi^+ \chi_{(u>0)}}{s_m^{-n-2} \int_{\partial B_{s_m}(x_0)} u^2 d\mathcal{H}^{n-1}}
\leq \frac{s_m^{-n-1} \int_{B_{r_m}(x_0)} \chi^+ \chi_{(u>0)}}{(r_m/2)^{-n-2} \int_{\partial B_{r_m/2}(x_0)} u^2 d\mathcal{H}^{n-1}}
\leq \frac{1}{2} \int_{\partial B_{r_m/2}(x_0)} u^2 d\mathcal{H}^{n-1} V(r_m)
= \frac{1}{2} \int_{\partial B_{r_m/2}} v_m^2 d\mathcal{H}^{n-1} V(r_m). \tag{8.6}
$$

Since, at least along a subsequence,

$$
\int_{\partial B_{r_m/2}} v_m^2 d\mathcal{H}^{n-1} \to \int_{\partial B_{r_m/2}} v_0^2 d\mathcal{H}^{n-1} > 0,
$$

8.6 leads to a contradiction. It follows that indeed $V(r) \to 0$ as $r \downarrow 0$. This implies that $D(r) \to F_{x^0, u}(0+)$. 
(ii) Let \( r_m \) be an arbitrary sequence with \( r_m \downarrow 0 \). The boundedness of the sequence \( v_m \) in \( W^{1,2}(B_1) \) is equivalent to the boundedness of \( D(r_m) \), which is true by (i).

(iii) Let \( r_m \downarrow 0 \) be an arbitrary sequence such that \( v_m \) converges weakly to \( v_0 \). The homogeneity degree \( F_{\varphi, u}(0+) \) of \( v_0 \) follows directly from (8.5). The homogeneity of \( v_0 \), together with the fact that \( v_0 \) belongs to \( W^{1,2}(B_1) \), imply that \( v_0 \) is continuous. The fact that \( \int_{\partial B_1} v_m^2 \, dH^{n-1} = 1 \) for all \( m \), and the remaining claims of the Proposition are obvious.

9. Concentration compactness in two dimensions

In the two-dimensional case we prove concentration compactness which allows us to preserve variational solutions in the blow-up limit at degenerate points and excludes concentration. In order to do so we combine the concentration compactness result of Evans and Müller [12] with information gained by our Frequency Formula. In addition, we obtain strong convergence of our blow-up sequence which is necessary in order to prove our main theorems. The question whether the following Theorem holds in any dimension seems to be a hard one.

**Theorem 9.1.** Let \( n = 2 \), let \( u \) be a variational solution of (3.1), and let \( x^0 \in \Sigma^u \). Let \( r_m \downarrow 0 \) be such that the sequence \( v_m \) given by (8.1) converges weakly to \( v_0 \) in \( W^{1,2}(B_1) \). Then \( v_m \) converges to \( v_0 \) strongly in \( W^{1,2}_{\text{loc}}(B_1 \setminus \{0\}) \), and \( v_0 \) satisfies \( v_0 \Delta v_0 = 0 \) in the sense of Radon measures on \( B_1 \).

**Proof.** Note first that, since \( v_0 \) is by Proposition 8.1 a nonnegative continuous function, \( v_0 \Delta v_0 \) is well defined as a nonnegative Radon measure on \( B_1 \).

Let \( \sigma \) and \( \varrho \) with \( 0 < \varrho < \sigma < 1 \) be arbitrary. We know that \( \Delta v_m \geq 0 \) and \( \Delta v_m(B(\sigma+1/2)) \leq C_1 \) for all \( m \). In order to apply the concentrated compactness result [12], we regularize each \( v_m \) to

\[
\tilde{v}_m := v_m * \phi_m \in C^\infty(B_1),
\]

where \( \phi_m \) is a standard mollifier such that

\[
\Delta \tilde{v}_m \geq 0, \quad \int_{B_\varrho} \Delta \tilde{v}_m \leq C_2 < +\infty \quad \text{for all } m,
\]

and

\[
\|v_m - \tilde{v}_m\|_{W^{1,2}(B_\varrho)} \to 0 \quad \text{as } m \to \infty.
\]

From [11] Chapter 4, Theorem 3] we know that \( \nabla \tilde{v}_m \) converges a.e. to the weak limit \( \nabla v_0 \), and the only possible problem is concentration of \( |\nabla \tilde{v}_m|^2 \). By [12] Theorem 1.1 and [12] Theorem 3.1] we obtain that

\[
\partial_1 \tilde{v}_m \partial_2 \tilde{v}_m \to \partial_1 v_0 \partial_2 v_0
\]

and

\[
(\partial_1 \tilde{v}_m)^2 - (\partial_2 \tilde{v}_m)^2 \to (\partial_1 v_0)^2 - (\partial_2 v_0)^2
\]
in the sense of distributions on $B_\sigma$ as $m \to \infty$. It follows that
\[ \partial_1 v_m \partial_2 v_m \to \partial_1 v_0 \partial_2 v_0 \quad (9.1) \]
and
\[ (\partial_1 v_m)^2 - (\partial_2 v_m)^2 \to (\partial_1 v_0)^2 - (\partial_2 v_0)^2 \]
in the sense of distributions on $B_\sigma$ as $m \to \infty$. Let us remark that this alone would allow us to pass to the limit in the domain variation formula for $v_m$ in the set $\{x_2 > 0\}$.

Observe now that (8.5) shows that
\[ \nabla v_m(x) \cdot x - F_{x^0, u}(0+) v_m(x) \to 0 \]
strongly in $L^2(B_\sigma \setminus B_\rho)$ as $m \to \infty$. It follows that
\[ \partial_1 v_m x_1 + \partial_2 v_m x_2 \to \partial_1 v_0 x_1 + \partial_2 v_0 x_2 \]
strongly in $L^2(B_\sigma \setminus B_\rho)$ as $m \to \infty$. But then
\[ \int_{B_\sigma \setminus B_\rho} (\partial_1 v_m \partial_1 v_m x_1 + \partial_1 v_m \partial_2 v_m x_2) \eta(x) \, dx \]
\[ \to \int_{B_\sigma \setminus B_\rho} (\partial_1 v_0 \partial_1 v_0 x_1 + \partial_1 v_0 \partial_2 v_0 x_2) \eta(x) \, dx \]
for each $\eta \in C^0_0(B_\sigma \setminus B_\rho)$ as $m \to \infty$. Using (9.1), we obtain that
\[ \int_{B_\sigma \setminus B_\rho} (\partial_1 v_m)^2 x_1 \eta(x) \, dx \to \int_{B_\sigma \setminus B_\rho} (\partial_1 v_0)^2 x_1 \eta(x) \, dx \]
for each $0 \leq \eta \in C^0_0((B_\sigma \setminus B_\rho) \cap \{x_1 > 0\})$ and for each $0 \geq \eta \in C^0_0((B_\sigma \setminus B_\rho) \cap \{x_1 < 0\})$ as $m \to \infty$. Repeating the above procedure three times for rotated sequences of solutions (by 45 degrees) yields that $\nabla v_m$ converges strongly in $L^2_{\text{loc}}(B_\sigma \setminus B_\rho)$. Since $\sigma$ and $\rho$ with $0 < \rho < \sigma < 1$ were arbitrary, it follows that $\nabla v_m$ converges to $\nabla v_0$ strongly in $L^2_{\text{loc}}(B_1 \setminus \{0\})$.

As a consequence of the strong convergence, we see that
\[ \int_{B_1} \nabla (\eta v_0) \cdot \nabla v_0 = 0 \quad \text{for all } \eta \in C^1_0(B_1 \setminus \{0\}). \]
Combined with the fact that $v_0 = 0$ in $B_1 \cap \{x_2 \leq 0\}$, this proves that $v_0 \Delta v_0 = 0$ in the sense of Radon measures on $B_1$. \qed

10. Degenerate points in two dimensions

**Theorem 10.1.** Let $n = 2$ and let $u$ be a variational solution of (3.1). Then at each point $x^0$ of the set $\Sigma^u$ there exists an integer $N(x^0) \geq 2$ such that
\[ F_{x^0, u}(0+) = N(x^0) \]
and
\[
\frac{u(x^0 + rx)}{\sqrt{r^{-1} \int_{\partial B_r(x^0)} u^2 \, dH^1}} \to \frac{\rho^{N(x^0)} |\sin(N(x^0) \theta)|}{\sqrt{\int_0^{2\pi} \sin^2(N(x^0) \theta) \, d\theta}}
\]
as \( r \to 0 \), strongly in \( W_{loc}^{1,2}(B_1 \setminus \{0\}) \) and weakly in \( W^{1,2}(B_1) \), where \( x = (\rho \cos \theta, \rho \sin \theta) \).

**Proof.** Let \( r_m \to 0 \) be an arbitrary sequence such that the sequence \( v_m \) given by (8.1) converges weakly in \( W_{loc}^{1,2}(B_1) \) to a limit \( v_0 \). By Proposition 8.1 (iii) and Theorem 10.1, \( v_0 \neq 0 \), \( v_0 \) is homogeneous of degree \( F_{x^0, u}(0^+) \geq 3/2 \), \( v_0 \) is continuous, \( v_0 \geq 0 \) and \( v_0 \equiv 0 \) in \( \{x_2 \leq 0\} \), \( v_0 \Delta v_0 = 0 \) in \( B_1 \) as a Radon measure, and the convergence of \( v_m \) to \( v_0 \) is strong in \( W_{loc}^{1,2}(B_1 \setminus \{0\}) \). Moreover, the strong convergence of \( v_m \) and the fact proved in Proposition 8.1 (i) that \( V(r_m) \to 0 \) as \( m \to \infty \) imply that
\[
0 = \int_{B_1} \left( |\nabla v_0|^2 \div \phi - 2 \nabla v_0 \partial \phi \nabla v_0 \right)
\]
for every \( \phi \in C_c^1(B_1 \cap \{x_2 > 0\}; \mathbb{R}^2) \). It follows that at each polar coordinate point \((1, \theta) \in \partial B_1 \setminus \partial \{v_0 > 0\}\),
\[
\lim_{\tau \searrow \theta} \partial_{\theta} v_0(1, \tau) = -\lim_{\tau \nearrow \theta} \partial_{\theta} v_0(1, \tau).
\]
Computing the solution of the ODE on \( \partial B_1 \), using the homogeneity of degree \( F_{x^0, u}(0^+) \) of \( v_0 \) and the fact that \( \int_{\partial B_1} v_0^2 \, dH^1 = 1 \), yields that \( F_{x^0, u}(0^+) \) must be an integer \( N(x^0) \geq 2 \) and that
\[
v_0(\rho, \theta) = \frac{\rho^{N(x^0)} |\sin(N(x^0) \theta)|}{\sqrt{\int_0^{2\pi} \sin^2(N(x^0) \theta) \, d\theta}}.
\]
The desired conclusion follows from Proposition 8.1 (ii). \hfill \Box

**Theorem 10.2.** Let \( n = 2 \) and let \( u \) be a variational solution of (3.1). Then the set \( \Sigma^u \) is locally in \( \Omega \) a finite set.

**Proof.** Suppose towards a contradiction that there is a sequence of points \( x_m^u \in \Sigma^u \) converging to \( x^0 \in \Omega \), with \( x_m^u \neq x^0 \) for all \( m \). From the upper semicontinuity Lemma 4.2 (iv) we infer that \( x^0 \in \Sigma^u \). Choosing \( r_m := 2|x_m^u - x^0| \), there is no loss of generality in assuming that the sequence \( (x_m^u - x^0)/r_m \) is constant, with value \( z \in \{(-1/2, 0), (1/2, 0)\} \). Consider the blow-up sequence \( v_m \) given by (8.1), and also the sequence
\[
u_m(x) = u(x^0 + r_m x)/r_m^{3/2}.
\]
Note that each \( u_m \) is a variational solution of (3.1), and \( v_m \) is a scalar multiple of \( u_m \). Since \( x_m^u \in \Sigma^u \), it follows that \( z \in \Sigma^{u_m} \). Therefore, Lemma 6.4 shows that, for each \( m \),
\[
\int_{B_r(z)} |\nabla v_m|^2 \geq \frac{3}{2} \int_{\partial B_r(z)} v_m^2 \, dH^1 \quad \text{for all } r \in (0, 1/2).
\]
It is a consequence of Theorem 10.1 that the sequence $v_m$ converges strongly in $W^{1,2}(B_{1/4}(z))$ to $v_0$ given by (10.1), hence
\[
\int_{B_r(z)} |\nabla v_0|^2 \geq \frac{3}{2} \int_{\partial B_r(z)} v_0^2\,dH^1 \quad \text{for all } r \in (0, 1/4).
\]
But this contradicts the fact, which can be checked directly, that
\[
\lim_{r \searrow 0} \frac{\int_{B_r(z)} |\nabla v_0|^2}{\int_{\partial B_r(z)} v_0^2\,dH^1} = 1.
\]

\[
\square
\]

11. Conclusion

Theorem 11.1. Let $n = 2$, let $u$ be a weak solution of (3.1), and suppose that
\[
|\nabla u|^2 \leq x_2^+ \quad \text{in } \Omega.
\]
Then the set $S^u$ of stagnation points is a finite or countable set. Each accumulation point of $S^u$ is a point of the locally finite set $\Sigma^u$.

At each point $x^0$ of $S^u \setminus \Sigma^u$,
\[
\frac{u(x^0 + rx)}{r^{3/2}} \to \frac{\sqrt{2}}{3} \rho^{3/2} \max(\cos(3(\theta - \pi/2)/2), 0) \quad \text{as } r \searrow 0,
\]
strongly in $W^{1,2}_{\text{loc}}(\mathbb{R}^2)$ and locally uniformly on $\mathbb{R}^2$, where $x = (\rho \cos \theta, \rho \sin \theta)$.

Moreover,
\[
L^2(B_1 \cap \{x : u(x^0 + rx) > 0\}) \neq \{\cos(3(\theta - \pi/2)/2) > 0\}) \to 0 \quad \text{as } r \searrow 0,
\]
and, for each $\delta > 0$,
\[
r^{-3/2} \Delta u(x^0 + B_r) \cap \{\cos(3(\theta - \pi/2)/2) > \delta\} \cup \{\cos(3(\theta - \pi/2)/2) < -\delta\}) \to 0
\]
as $r \searrow 0$.

At each point $x^0$ of $\Sigma^u$ there exists an integer $N(x^0) \geq 2$ such that
\[
\frac{u(x^0 + rx)}{r^\beta} \to 0 \quad \text{as } r \searrow 0,
\]
strongly in $L^2_{\text{loc}}(\mathbb{R}^2)$ for each $\beta \in [0, N(x^0))$, and
\[
\frac{u(x^0 + rx)}{\sqrt{r^{-1} \int_{B_r(x^0)} u^2\,dH^1}} \to \frac{\rho^{N(x^0)} |\sin(N(x^0)\theta)|}{\sqrt{\int_{0}^{2\pi} \sin^2(N(x^0)\theta)\,d\theta}} \quad \text{as } r \searrow 0,
\]
strongly in $W^{1,2}_{\text{loc}}(B_1 \setminus \{0\})$ and weakly in $W^{1,2}(B_1)$, where $x = (\rho \cos \theta, \rho \sin \theta)$.

Proof. By Lemma 3.3 $u$ is a variational solution of (3.1) and satisfies
\[
r^{-3/2} \int_{B_r(y)} \sqrt{x_2 |\nabla \chi_{u>0}|} \leq C_0
\]
for all $B_r(y) \subseteq \Omega$ such that $y_n = 0$. Combining Proposition \ref{prop:2} Proposition \ref{prop:3} Lemma \ref{lem:4} Lemma \ref{lem:5} Proposition \ref{prop:6} Lemma \ref{lem:7} Theorem \ref{thm:8} and Theorem \ref{thm:9} we obtain that the set $S^u$ is a finite or countable set with asymptotics as in the statement, and that the only possible accumulation points are elements of $\Sigma^u$.

\begin{theorem}
Let $n = 2$, let $u$ be a weak solution of \eqref{eq:3.1}, and suppose that
\[|\nabla u|^2 \leq x_2^+ \text{ in } \Omega.\]

Suppose moreover that $\{u = 0\}$ has locally only finitely many connected components. Then the set $S^u$ of stagnation points is locally in $\Omega$ a finite set. At each stagnation point $x^0$,
\[
\frac{u(x^0 + r x)}{r^{3/2}} \to \frac{\sqrt{2}}{3} \rho^{3/2} \max(\cos(3(\theta - \pi/2)/2), 0) \quad \text{as } r \to 0,
\]

strongly in $W^{1,2}_{\text{loc}}(\mathbb{R}^2)$ and locally uniformly on $\mathbb{R}^2$, where $x = (\rho \cos \theta, \rho \sin \theta)$, and in an open neighborhood of $x^0$ the topological free boundary $\partial\{u > 0\}$ is the union of two $C^1$-graphs with right and left tangents at $x^0$.

\end{theorem}

\begin{proof}
We first show that the set $\Sigma^u$ is empty. Suppose towards a contradiction that there exists $x^0 \in \Sigma^u$. From Theorem \ref{thm:10} we infer that there exists an integer $N(x^0) \geq 2$ such that
\[
\frac{u(x^0 + r x)}{\sqrt{r^{-1} \int_{\partial B_r(x^0)} u^2 dH^1}} \to \frac{\sin(N(x^0)\theta)}{\sqrt{\int_{0}^{2\pi} \sin^2(N(x^0)d\theta) d\theta}} \text{ as } r \to 0,
\]

strongly in $W^{1,2}_{\text{loc}}(B_1 \setminus \{0\})$ and weakly in $W^{1,2}(B_1)$, where $x = (\rho \cos \theta, \rho \sin \theta)$. But then the assumption about connected components implies that $\partial_{\text{red}}\{x : u(x^0 + r x) > 0\}$ contains the image of a continuous curve converging, as $r \to 0$, locally in $\{x_2 > 0\}$ to a half-line $\{\alpha z : \alpha > 0\}$ where $z_2 > 0$. It follows that
\[
H^1(\{x_2 > 1/2\} \cap \partial_{\text{red}}\{x : u(x^0 + r x) > 0\}) \geq c_1 > 0,
\]

contradicting
\[
0 \leftarrow \Delta \frac{u(x^0 + r x)}{r^{3/2}}(B_1) = \int_{B_1 \cap \partial_{\text{red}}\{x : u(x^0 + r x) > 0\}} \sqrt{x_2} dH^1.
\]

Hence $\Sigma^u$ is indeed empty.

Let $x^0 \in S^u$. Theorem \ref{thm:11} shows that
\[
\frac{u(x^0 + r x)}{r^{3/2}} \to \frac{\sqrt{2}}{3} \rho^{3/2} \max(\cos(3(\theta - \pi/2)/2), 0) \quad \text{as } r \to 0,
\]

strongly in $W^{1,2}_{\text{loc}}(\mathbb{R}^2)$ and locally uniformly on $\mathbb{R}^2$, where $x = (\rho \cos \theta, \rho \sin \theta)$. To prove the last statement we now use flatness-implies-regularity results in the vein of \cite[Theorem 8.1]{2}. More precisely, for each $\sigma \leq \sigma_0$ and $y^0 \in B_{r/2}(x^0) \cap \partial\{u > 0\} \cap \{y_1 < x_1^0\}$, $u \in F(\sigma, 0; \sigma_0\sigma^2)$ in $B_{r/2}(y^0)$ in the direction $\eta = (1/2, -\sqrt{3}/2)$ (cf.
Definition 4.1]) provided that $\delta$ has been chosen small enough, meaning that $u$ is a weak solution and satisfies

$$u(x) = 0 \quad \text{in} \quad \{x \in B_r(y^0) : x \cdot \eta \geq \sigma r\}$$

and

$$|\nabla u| \leq \sqrt{y^0_2(1 + \sigma_0 \sigma^2)} \quad \text{in} \quad B_r(y^0).$$

From the proof of [5, Theorem 8.4] (with the proviso that the parabolic monotonicity formula in [5] is replaced by the local elliptic formula in Theorem 3.5 (i) and the solution has been extended to a constant function of the time variable) we infer that $B_r/2(x^0) \cap \partial \{u > 0\} \cap \{y^0_1 < x^0_1\}$ is the graph of a $C^{1,\alpha}$-function and that the outer normal $\nu$ satisfies $|\nu(y^0_0) - \eta| \leq \sigma$. It follows that $B_\delta(x^0) \cap \partial \{u > 0\} \cap \{y^0_1 \leq x^0_1\}$ is the graph of a $C^{1}$-function. The same holds for $B_\delta(x^0) \cap \partial \{u > 0\} \cap \{y^0_1 \geq x^0_1\}$. □

12. Appendix

Proof of Lemma 3.4. For any $\phi \in C^1_0(\Omega \cap \{x_n > \tau\}; \mathbb{R}^n)$ and small positive $\delta$ we find a covering

$$\bigcup_{i=1}^{\infty} B_{r_i}(x^i) \supset \text{supp} \phi \cap (\partial \{u > 0\} \setminus \partial_{\text{red}} \{u > 0\})$$

satisfying $\sum_{i=1}^{\infty} r_i^{n-1} \leq \delta$, and by the fact that $\text{supp} \phi \cap (\partial \{u > 0\} \setminus \partial_{\text{red}} \{u > 0\})$ is a compact set we may pass to a finite subcovering

$$\bigcup_{i=1}^{N_\delta} B_{r_i}(x^i) \supset \text{supp} \phi \cap (\partial \{u > 0\} \setminus \partial_{\text{red}} \{u > 0\})$$

satisfying $\sum_{i=1}^{N_\delta} r_i^{n-1} \leq \delta$.

We also know that $u \in C^1(\{u > 0\} \cap (\text{supp} \phi \setminus \bigcup_{i=1}^{N_\delta} B_{r_i}(x^i)))$ and that $u$ satisfies the free-boundary condition

$$|\nabla u|^2 = x_n \quad \text{on} \quad \partial_{\text{red}} \{u > 0\} \cap (\text{supp} \phi \setminus \bigcup_{i=1}^{N_\delta} B_{r_i}(x^i)).$$

Formally integrating by parts in $\{u > 0\} \setminus \bigcup_{i=1}^{N_\delta} B_{r_i}(x^i)$ (this can be justified rigorously approximating $\bigcup_{i=1}^{N_\delta} B_{r_i}(x^i)$ from above by $A_\varepsilon$ such that $\partial(\{u > 0\} \setminus A_\varepsilon)$ is
and the weak solution property, it follows that

\[
\left| \int_\Omega \left( |\nabla u|^2 \text{div } \phi - 2\nabla u D\phi \nabla u + x_n \chi_{\{u>0\}} \text{div } \phi + \chi_{\{u>0\}} \phi_n \right) \right| \\
\leq \left| \int_{\mathcal{B}_1} \left( |\nabla u|^2 \text{div } \phi - 2\nabla u D\phi \nabla u + x_n \chi_{\{u>0\}} \text{div } \phi + \chi_{\{u>0\}} \phi_n \right) \right| \\
+ \left| \int_{\partial(\cup_{i=1}^{N_i} B_{r_i}(x_i)) \cap \{u>0\}} \left( |\nabla u|^2 \phi \cdot \nu - 2\nabla u \cdot \nu \nabla u \cdot \phi + x_n \phi \cdot \nu \right) d\mathcal{H}^{n-1} \right| \\
+ \left| \int_{\partial\{u>0\} \setminus (\cup_{i=1}^{N_i} B_{r_i}(x_i))} (x_n - |\nabla u|^2) \phi \cdot \nu d\mathcal{H}^{n-1} \right| \\
\leq C_1 \sum_{i=1}^{N_i} r_i^n + C_2 \sum_{i=1}^{N_i} r_i^{n-1} + 0,
\]

and letting \( \delta \to 0 \), we realize that \( u \) is a variational solution of \( \Xi \) in the set \( \Omega \cap \{x_n > \tau\} \). Note that the above extends to Lipschitz functions \( \phi \). Next, let us take \( \phi \in C_0^0(\Omega; \mathbb{R}^n) \) and \( \eta := \min(1, x_n/\tau) \), plug in the product \( \eta \phi \) into the already obtained result, and use the assumption \( |\nabla u|^2 \leq C x_n^+ \):

\[
0 = \int_\Omega \eta \left( |\nabla u|^2 \text{div } \phi - 2\nabla u D\phi \nabla u + x_n \chi_{\{u>0\}} \text{div } \phi + \chi_{\{u>0\}} \phi_n \right) \\
+ \frac{1}{\tau} \int_{\Omega \cap \{0 < x_n < \tau\}} \phi \cdot \left( |\nabla u|^2 e_n - 2\partial_n u \nabla u + x_n \chi_{\{u>0\}} e_n \right) \\
= o(1) + \int_\Omega \left( |\nabla u|^2 \text{div } \phi - 2\nabla u D\phi \nabla u + x_n \chi_{\{u>0\}} \text{div } \phi + \chi_{\{u>0\}} \phi_n \right) \quad \text{as } \tau \to 0.
\]

Last, let us prove that

\[
r^{1/2-n} \int_{B_{r}(y)} \sqrt{x_n} |\nabla \chi_{\{u>0\}}| \leq C_0
\]

for all \( B_{r}(y) \subset \subset \Omega \) such that \( y_n = 0 \). Let us consider such an \( y \), and the family of scaled functions

\[
u_r(x) := u(y + rx)/r^{3/2}.
\]

Using the assumption

\[
|\nabla u|^2 \leq C x_n^+ \quad \text{locally in } \Omega
\]

and the weak solution property, it follows that

\[
C_0 \geq \int_{\partial B_1} \nabla u_r(x) \cdot x d\mathcal{H}^{n-1} = \Delta u_r(B_1)
\]

\[
= \int_{B_1 \cap \partial_{\text{red}} \{u_r>0\}} \sqrt{x_n} d\mathcal{H}^{n-1} = r^{1/2-n} \int_{B_r(y) \cap \partial_{\text{red}} \{u>0\}} \sqrt{x_n} d\mathcal{H}^{n-1},
\]

as required. \qed
Proof of Proposition 5.8. The proof is a standard dimension reduction argument following [15, Section 11]. In each step, blowing up once transforms the free boundary into a cone, blowing up a second time at a point different from the origin transforms the free boundary into a cylinder, and passing to a codimension 1 cylinder section reduces the dimension of the whole problem by 1.

Let us do this in some more detail: Suppose that there exists \( s > n - 2 \) and \( \varsigma > 0 \), \( \kappa > 0 \) such that \( \mathcal{H}^s(N^u_{\varsigma, \kappa}) > 0 \). Then we may use [15, Proposition 11.3], Lemma 5.7 as well as [15, Lemma 11.5] at \( \mathcal{H}^s \)-a.e. point of \( N^u_{\varsigma, \kappa} \) to obtain a blow-up limit \( u_0 \) satisfying \( \mathcal{H}^{s, \infty}(N^u_{\varsigma, \kappa}) > 0 \). According to Lemma 4.1 \( u_0 \) is a homogeneous variational solution on \( \mathbb{R}^n \), where \( \chi(n > 0) \) has to be replaced by \( \chi_0 := \lim_{m \to \infty} \chi(u_m > 0) \) in Definition 3.1. We proceed with the dimension reduction: By [15, Lemma 11.2] we find a point \( \bar{x} \in N^u_{\varsigma, \kappa} \setminus \{0\} \) at which the density in [15, Proposition 11.3] is estimated from below. Now each blow-up limit \( u_{00} \) with respect to \( \bar{x} \) (and with respect to a subsequence \( m \to \infty \) such that the limit superior in [15, Proposition 11.3] becomes a limit) again satisfies the assumptions of Lemma 4.1. In addition, we obtain from the homogeneity of \( u_{00} \) as in Lemma 3.1 of [37] that the rotated \( u_{00} \) is constant in the direction of the \( n \)-th unit vector. Defining \( \bar{u} \) as the restriction of this rotated solution to \( \mathbb{R}^{n-1} \), it follows therefore that \( \mathcal{H}^{s-1}(N^u_{\varsigma, \kappa}) > 0 \). Repeating the whole procedure \( n - 2 \) times we obtain a nontrivial homogeneous solution \( u^* \) in \( \mathbb{R}^2 \), satisfying \( \mathcal{H}^{s-(n-2)}(N^u_{\varsigma, \kappa}) > 0 \), by Proposition 4.7 a contradiction. \( \square \)
