Next-nearest-neighbor spin-spin and chiral-spin correlation functions in generalized XXX chain

V. V. Mkhitaryan and A. G. Sedrakyan
Yerevan Physics Institute, Br. Alikhanian str.2, Yerevan 36, Armenia

We develop a simple technique for calculation of next to nearest neighbor spin-spin and chiral-spin correlation functions in inhomogeneous XXX model. Exact expression of the chiral-spin order parameter as a function of the model parameter, $\omega$, is analytically found. Using the same method we also calculate the next to nearest neighbor spin-spin correlation function. In the limit $\omega \to 0$ it reproduces the known result for the vacuum expectation value of the next to nearest neighbor spins in the standard Heisenberg spin chain. The technique is simple and can be extended for calculation of next to next to nearest neighbor correlation functions as well as for calculation of correlation functions in XXZ model.

I. INTRODUCTION

Presently, calculation of correlation functions in strongly correlated electron systems is one of the most important tasks in physics of low dimensions. Correlation functions of spins at large distances are directly related to the observable quantities. They define a set of critical indices identifying the universality classes of different phases. Notably, correlation functions of spins in the homogeneous Heisenberg spin chain (XXX model) at short distances are not directly related to the universality class of the phase, but, as it appears, they play an important role in the perturbative investigations of ladder models, that are not integrable. An important example is the Haldane ladder model, that can be approached as an Heisenberg spin chain perturbed with the chiral-spin order parameter, $\sigma_n(\sigma_{n+1} \times \sigma_{n+2})$, (which was considered earlier in connection with spin-liquid ordered phase in Ref[1]) and by the product of next to nearest neighbor spins $\sigma_n \sigma_{n+2}$. In order to investigate the free energy of this long term attractive model and analyze the phase space, one needs to know the correlation function of the next to nearest neighbor spins and the chiral-spin order parameter $\chi_n = \langle \sigma_n(\sigma_{n+1} \times \sigma_{n+2})\rangle$.

The aim of the present work is the calculation of abovementioned correlation functions for a generalized XXX model by a new simple technique. This model is defined and studied in Section II. The studies of Section II involve analysis of the Hamiltonian(s) and other conserved currents, construction of the Transfer matrix and obtaining the set of Bethe equations that describe the energy spectrum. Two particular cases of the generalized XXX model are the ladder systems with $N$ sites at each chain given by Hamiltonian operators

$$
\mathcal{H} = 2 \sum_{n=1}^{2N} [\sigma_n \sigma_{n+1} - 1] + \omega^2 \sum_{n=1}^{2N} [\sigma_n \sigma_{n+2} - 1] + \omega \sum_{n=1}^{2N} (-1)^n \sigma_{n-1}(\sigma_n \times \sigma_{n+1}),
$$

$$
\mathcal{H}' = \omega^2 \sum_{n=1}^{2N} (-1)^{n} [\sigma_n \sigma_{n+2} - 1] - \omega \sum_{n=1}^{2N} \sigma_{n-1}(\sigma_n \times \sigma_{n+1}).
$$

As a manifestation of the effective workability of the developed technique in Section III we first calculate the exact correlation functions of the next to nearest neighbor spins, $\xi(\omega) = \langle \sigma_n \sigma_{n+2} - 1 \rangle$, as a function of $\omega$, which for the Hamiltonian Eq. 1 has the following asymptotic behavior:

$$
\xi(\omega) = \begin{cases} 
-16 \log(2) + 9\zeta(3) - 1, 41\omega^2, & \text{for } \omega \ll 1 \\
-2, 77 + \frac{177}{\omega^2}, & \text{for } \omega \gg 1. 
\end{cases}
$$

Here $\zeta(x)$ is the Riemann zeta function. In the limit $\omega = 0$, we reproduce the known result for the expectation value of next to nearest neighbor exchange operator in the standard XXX chain, first obtained by involving the Hubbard model[2].

More recently, within the general approach of multiple integral representation of correlation functions, that was formulated in Ref. 13 and investigated further in Refs. 14 and 17, correlation functions $\langle \sigma_n \sigma_{n+3} \rangle$ and $\langle \sigma_n \sigma_{n+4} \rangle$ were evaluated. These functions were evaluated for XXX model in zero magnetic field. One of the advantages of our technique is the possibility to include also external magnetic field. This can be done by involving the magnetic field into the integral equations for the densities. In some cases such integral equations can be solved by approximate methods.

Our main result, however, is the analytical calculation of the chiral-spin order parameter, $\langle \sigma_n(\sigma_{n+1} \times \sigma_{n+2}) \rangle = (-1)^n \chi_n(\omega)$, as a function of staggering parameter, $\omega$. The full expression and the derivation of $\chi_n$ are presented in Section III. Here we present only the asymptotes of the
function \( \chi(\omega) \),

\[
\chi(\omega) = \begin{cases} 
8\gamma + 8\psi(1/2) - \psi''(1/2) + \psi''(1), & \text{for } \omega \ll 1, \\
3.545 \, \omega, & \text{for } \omega \gg 1,
\end{cases}
\]

(4)

where \( \gamma \) is the Euler constant, the function \( \psi \) is the Digamma function and the coefficient of linearity for small \( \omega \) is \( \approx 3.33. \)

We would like to note that this correlation function was previously investigated numerically and also spins that are far from each other. Usually the further neighbor interactions and other non-localities come from additional anisotropy parameters. We will consider a family of models with nearest neighbor, next to nearest neighbor and triangular (zig-zag) interactions, which stem from the Transfer matrix with the shift of the spectral parameters at each second sites:

\[
\Theta(\lambda; \omega) = L_{2N,a}(\lambda) L_{2N-1,a}(\lambda - \omega) \cdots L_{2,a}(\lambda - \omega).
\]

(5)

Here \( L_{a,b}(\lambda) \) obeys the Rational Yang-Baxter relations

\[
R_{a1,a2}(\lambda - \mu)L_{n,a1}(\lambda)L_{n,a2}(\mu) = L_{n,a2}(\mu)L_{n,a1}(\lambda)R_{a1,a2}(\lambda - \mu)
\]

(6)

with rational

\[
L_{n,a}(\lambda) = (\lambda - i/2)I_{n,a} + iP_{n,a},
\]

(7)

\[
R_{a,b}(\lambda) = \lambda I_{a,b} + iP_{a,b}.
\]

The permutation operator is given in terms of Pauli matrices as

\[
P_{a,b} = \frac{1}{2} (I_a \otimes I_b + \sum_\alpha \sigma^\alpha \otimes \sigma^\alpha).
\]

With this construction, one has a commuting one parametrical family of transfer matrices \( \tau(\lambda; \omega) = tr_a \Theta(\lambda; \omega) : \)

\[
[\tau(\lambda; \omega), \tau(\mu; \omega)] = 0.
\]

This is a well known picture, see e.g. \cite{8910,8120}, while we want to apply this in a slightly different contents. In order to be shorter we will miss some proofs and refer the reader to the nice review by L. D. Faddeev.

The interesting feature of the Transfer matrix \( \Theta(\lambda; \omega) \), given by Eq. (5), is that instead of usual XXX Hamiltonian this yields two different local Hamiltonian operators, \( H_1 \) and \( H_2 \), that are proportional to the logarithmic derivative of \( \tau \) at two different points: \( \lambda = i/2 \) and \( \lambda = \omega + i/2 \). Respectively, their explicit forms are

\[
H_1 = 2i(1 + \omega^2)\partial_\lambda \ln \tau|_{\lambda=i/2} - N(2 + \omega^2 - 2i\omega)
\]

\[
= \sum_{n=1}^{2N} \{ \tilde{\sigma}_n \tilde{\sigma}_{n+1} - 1 \} + \sum_{k=1}^{N} \{ \omega^2 [ \tilde{\sigma}_{2k} \tilde{\sigma}_{2k+2} - 1] - \omega \tilde{\sigma}_{2k}(\tilde{\sigma}_{2k+1} \times \tilde{\sigma}_{2k+2}) \},
\]

(8)

\[
H_2 = 2i(1 + \omega^2)\partial_\lambda \ln \tau|_{\lambda=i/2+\omega} - N(2 + \omega^2 + 2i\omega)
\]

\[
= \sum_{n=1}^{2N} \{ \tilde{\sigma}_n \tilde{\sigma}_{n+1} - 1 \} + \sum_{k=1}^{N} \{ \omega^2 [ \tilde{\sigma}_{2k-1} \tilde{\sigma}_{2k+1} - 1] + \omega \tilde{\sigma}_{2k-1}(\tilde{\sigma}_{2k} \times \tilde{\sigma}_{2k+1}) \}.
\]

(9)

These operators are commuting as they belong to the same commuting family. It is straightforward that the Hamiltonian operators \( \mathcal{H} = H_1 - H_2 \) and \( \mathcal{H}' = H_1 + H_2 \) are exactly diagonalizable in the same framework. Their explicit forms are given by Eqs. (11) and (12).

Let quasi- shift operators be the monodromy matrices at the points \( \lambda = i/2 \) and \( \lambda = i/2 + \omega \):

\[
U_+ = tr_a \Theta(i/2; \omega),
\]

\[
U_- = tr_a \Theta(i/2 + \omega; \omega).
\]

(10)

They obey the relation

\[
(1 + \omega^2)^N V^2 = U_+ U_- = e^{iP},
\]

(11)

where

\[
V = P_{1,2} P_{2,3} \cdots P_{2N-1,2N}
\]

(12)

is a shift on one unit \( n \to n + 1 \), and \( P \) is the physical momentum, which governs the shift \( n \to n + 2 \). Being defined in this way, the quasi-shift operators commute with the whole family of transfer matrices \( \tau(\mu; \omega) \).

Derivation of the Bethe Ansatz Equations (BAE) for \( \tau(\mu; \omega) \) is standard, see e.g., Ref.\cite{8910}. Starting from the reference state with all \( 2N \) spins up one can generate the eigenvectors of the transfer matrix in the sector with \( M \) overturned spins, parametrized by \( M \) complex rapidities \( \lambda_n \) which obey BAE

\[
((\lambda_n + i/2)(\lambda_n - \omega + i/2)) = \prod_{k \neq n}^{M} \frac{\lambda_n - \lambda_k + i}{\lambda_n - \lambda_k - i}.
\]

(13)
The eigenvalues of the transfer-matrix $\tau(\mu; \omega)$ have the form

$$t(\mu) = [(\mu + i/2)(\mu - \omega + i/2)]^N \prod_{n=1}^{M} \frac{\mu - \lambda_n - i}{\mu - \lambda_n} + [(\mu - i/2)(\mu - \omega - i/2)]^N \prod_{n=1}^{M} \frac{\mu - \lambda_n + i}{\mu - \lambda_n}. \tag{14}$$

This gives the quasiparticle momentum in the form

$$e^{iP} = \prod_{n=1}^{M} \frac{(\lambda_n + i/2)(\lambda_n - \omega + i/2)}{(\lambda_n - i/2)(\lambda_n - \omega - i/2)}, \tag{15}$$

and eigenvalues of $H_1$ and $H_2$ as follows:

$$E_1(\{\lambda\}, \omega) = -2(1 + \omega^2) \sum_n \frac{1}{\lambda_n^2 + 1/4}, \tag{16}$$

$$E_2(\{\lambda\}, \omega) = -2(1 + \omega^2) \sum_n \frac{1}{(\lambda_n - \omega)^2 + 1/4}. \tag{17}$$

The corresponding eigenenergies of Eqs. (1) and (2) are $E_1 + E_2$ and $E_1 - E_2$ respectively. Now the picture is in some sense complete and one is in position to infer the thermodynamics of these models, based on the BAE and the energy relations. The particular Hamiltonian Eq. (1) was introduced in Ref. 11 and analyzed in details.19-23. It has a singlet ground state with massless excitations. By involving a magnetic field with the Zeeman coupling, the system undergoes two phase transitions; two critical phases with different universality classes are discussed in Ref. 21. The XXZ generalization of the model (2) was defined and investigated in15,24.

III. CHIRAL-SPIN AND OTHER CORRELATION FUNCTIONS

It is well known that the expectation values of operators not commuting with the Hamiltonian are not easily accessible within the framework of Bethe Ansatz. In the case of inhomogeneous chain under consideration we have the additional parameter $\omega$, which breaks the translational invariance $n \to n + 1$ and gives a possibility to calculate some simplest expectation values, that are valid also in the limit $\omega \to 0$, corresponding to the well known XXX case. For our purposes we need the eigenvalues of quasi-translation operators, which follow from (14) and the definition (10):

$$u_+ = (-1)^N(1 + i\omega)^N \prod_n \frac{\lambda_n + i/2}{\lambda_n - i/2}, \tag{18}$$

where $\{\mu\}$ is any set of BAE solution. Given in the above form, it is readily calculable. It does not depend on $n$, even on the parity of $n$ and shows that the model Eq. (1) can’t have a dimerized phase.

The next expectation value that we are going to evaluate is the next to nearest neighbor (NNN) exchange, $\langle \{\mu\}|\hat{\sigma}_n\hat{\sigma}_{n+2}|\{\mu\}\rangle$. For this purpose we divide the two Hamiltonian operators Eq. (5) by $\omega$ and apply Eq. (20). Subtracting contributions of nearest neighbor terms with the use of Eq. (21) we obtain for even or odd site numbers the following relations:

$$\partial_\omega U_+ = \sum_{k=1}^{N} \frac{iP_{2k,2k-1} + \omega}{1 + \omega^2} U_+$$

$$\partial_\omega U_- = -\sum_{k=1}^{N} \frac{iP_{2k,2k+1} - \omega}{1 + \omega^2} U_-$$
\[
\langle \{\mu\} \mid \sigma_{2k} \sigma_{2k+2} - 1 \mid \{\mu\} \rangle = \frac{1}{N} \partial_\omega E_1(\{\mu\}, \omega) + \frac{2}{\omega^2} \langle \{\mu\} \mid \sigma_n \sigma_{n+1} - 1 \mid \{\mu\} \rangle
\]
\[
= -\frac{4}{N} \sum_{m=1}^{M} \left\{ \frac{1 + \omega^2}{\omega^2} \frac{\partial_\omega \mu_m}{\mu_m^2 + \frac{1}{4}} + \frac{\omega^2 - 1}{2\omega^2} \frac{1}{\mu_m^2 + \frac{1}{4}} - \frac{1 + \omega^2}{\omega} \frac{(\mu_m - \omega)(\mu_m - \mu_m - 1)}{((\mu_m - \omega)^2 + \frac{1}{4})^2} \right\}
\]

and
\[
\langle \{\mu\} \mid \sigma_{2k-1} \sigma_{2k+1} - 1 \mid \{\mu\} \rangle = \frac{1}{N} \partial_\omega E_2(\{\mu\}, \omega) + \frac{2}{\omega^2} \langle \{\mu\} \mid \sigma_n \sigma_{n+1} - 1 \mid \{\mu\} \rangle
\]
\[
= -\frac{4}{N} \sum_{m=1}^{M} \left\{ \frac{1 + \omega^2}{\omega^2} \frac{\partial_\omega \mu_m}{\mu_m^2 + \frac{1}{4}} + \frac{\omega^2 - 1}{2\omega^2} \frac{1}{\mu_m^2 + \frac{1}{4}} - \frac{1 + \omega^2}{\omega} \frac{(\mu_m - \omega)(\mu_m - \mu_m - 1)}{((\mu_m - \omega)^2 + \frac{1}{4})^2} \right\}. 
\]

It is yet unknown how to perform such summations in the case of finite \( N \) and \( M \) analytically. Instead we can evaluate the sums in the important case of thermodynamic limit,

\[
N \to \infty, \quad M \to \infty, \quad \frac{M}{N} = \text{const}, \quad (24)
\]

when solutions of Eq. (13) form bound states called strings\(^7\). In our rational case strings with arbitrary length \( n \) are possible. Consider the case where one has \( M_n \) bound states of \( n \)-strings

\[
\lambda_{\alpha, n, j} = \lambda_{\alpha} + \frac{i}{2}(n + 1 - 2j) + O(\exp(-|\delta|N)),
\]

\[
\Theta_{nm}(\lambda) = \begin{cases} 
\theta(\frac{\lambda}{|n-m|}) + 2\theta(\frac{\lambda}{|n-m|+2}) + \ldots + 2\theta(\frac{\lambda}{n+m-2}) + \theta(\frac{\lambda}{n+m}) & \text{for } n \neq m, \\
2\theta(\frac{\lambda}{2}) + 2\theta(\frac{\lambda}{4}) + \ldots + 2\theta(\frac{\lambda}{n-2}) + \theta(\frac{\lambda}{n}) & \text{for } n = m.
\end{cases}
\]

\( I_n^\alpha \) is an integer (half-odd integer) if \( N - M_n \) is odd (even) and satisfies

\[
|I_n^\alpha| \leq \frac{1}{2}(N - 1 - \sum_{m=1}^{\infty} t_{nm} M_m),
\]
\[
t_{nm} \equiv 2M \ln(n, m) - \delta_{nm}. \quad (28)
\]

In the thermodynamic limit \( 24 \), it is convenient to define distribution functions of \( n \)-strings \( \rho_n(\lambda) \) and holes of \( n \)-string \( \tilde{\rho}_n(\lambda) \); the number of strings and holes between \( \lambda \) and \( \lambda + d\lambda \) is \( \rho_n(\lambda) N d\lambda \) and \( \tilde{\rho}_n(\lambda) N d\lambda \), respectively. From Eqs. (25) one obtains a system of integral equations

\[
a_n(\lambda) + a_n(\lambda - \omega) = \rho_n(\lambda) + \tilde{\rho}_n(\lambda) \quad (29)
\]
\[
+ \sum_m \int_{-\infty}^{\infty} T_{nm}(\lambda - \mu) \rho_m(\mu) d\mu,
\]

where \( T_{nm}(\lambda) \) is a function defined by

\[
T_{nm}(\lambda) = \begin{cases} 
2a_2(\lambda) + 2a_4(\lambda) + \ldots + 2a_{2n-2}(\lambda) + a_{2n}(\lambda) & \text{for } n = m, \\
+ 2a_{n+m-2}(\lambda) + a_{n+m}(\lambda) & \text{for } n \neq m,
\end{cases}
\]

\[
a_{|n-m|}(\lambda) + 2a_{|n-m|+2}(\lambda) + 2a_{|n-m|+4}(\lambda) + \ldots
\]

\[
\quad a_{|n-m|}(\lambda) + 2a_{|n-m|+2}(\lambda) + 2a_{|n-m|+4}(\lambda) + \ldots
\]

\[
\quad \text{for } n \neq m,
\]

\[
\quad \text{for } n = m.
\]
and \( a_n(\lambda) \) is a function defined by
\[
a_n(\lambda) = \frac{1}{\pi} \frac{2n}{4\lambda^2 + n^2}.
\]

In order to describe \( \omega \)- derivatives of \( \lambda_n^\omega \) in the thermodynamic limit, we introduce a new function, \( F_n \), as
\[
\lim_{N \to \infty} \partial_{\omega} \lambda_n^\omega F_n(\lambda, \omega).
\]
(31)

For brevity we will miss the explicit \( \omega \)- dependence of \( F \). In order to find a characteristic integral equation for this function, one can differentiate (26) with respect to \( \omega \) and use (29). In this way one finds:
\[
a_n(\lambda - \omega) = F_n(\lambda)[\rho_n(\lambda) + \tilde{\rho}_n(\lambda)]
\]
(32)
\[+ \sum_m \int_{-\infty}^{\infty} T_{nm}(\lambda - \mu) F_m(\mu) \rho_m(\mu) d\mu.\]

Now we can rewrite the R.H.S. sums in (22) in terms of integrals:
\[
\langle \mu \rangle |\bar{\sigma}_{2k-1} \bar{\sigma}_{2k+1} - 1 |\mu\rangle = -8\pi \sum_{n=1}^{\infty} \int \rho_n(\mu) d\mu \left\{ \frac{1 + \omega^2}{\omega^2} a_n(\mu) F_n(\mu) + \frac{\omega^2 - 1}{2\omega^2} a_n(\mu - \omega) + \frac{1 + \omega^2}{2\omega} a_n'(\mu - \omega) F_n(\mu) - 1 \right\},
\]
and
\[
\langle \mu \rangle |\bar{\sigma}_{2k} \bar{\sigma}_{2k+1} - 1 |\mu\rangle = -8\pi \sum_{n=1}^{\infty} \int \rho_n(\mu) d\mu \left\{ \frac{1 + \omega^2}{\omega^2} a_n(\mu) F_n(\mu) + \frac{\omega^2 - 1}{2\omega^2} a_n(\mu - \omega) + \frac{1 + \omega^2}{2\omega} a_n'(\mu - \omega) F_n(\mu) - 1 \right\}.
\]

Evaluation of the expectation value of triple interaction terms, the chiral-spin order parameter, can be done in a similar way. The answer is
\[
\langle \mu \rangle |\bar{\sigma}_{2k} (\bar{\sigma}_{2k+1} \times \bar{\sigma}_{2k+2}) |\mu\rangle = -4\pi \sum_{n=1}^{\infty} \int \rho_n(\mu) d\mu \left\{ \frac{4}{\omega^2} + \frac{1 + \omega^2}{\omega} a_n(\mu) F_n(\mu) + \frac{\omega^2 - 1}{2\omega^2} a_n(\mu - \omega) + \frac{1 + \omega^2}{2\omega} a_n'(\mu - \omega) F_n(\mu) - 1 \right\}.
\]
(35)

and
\[
\langle \mu \rangle |\bar{\sigma}_{2k-1} \bar{\sigma}_{2k} \times \bar{\sigma}_{2k+1} |\mu\rangle = 4\pi \sum_{n=1}^{\infty} \int \rho_n(\mu) d\mu \left\{ \frac{4}{\omega^2} + \frac{1 + \omega^2}{\omega} a_n(\mu) F_n(\mu) + \frac{\omega^2 - 1}{2\omega^2} a_n(\mu - \omega) + \frac{1 + \omega^2}{2\omega} a_n'(\mu - \omega) F_n(\mu) - 1 \right\}.
\]
(36)

For definiteness, let us evaluate the NNN expectation value for the ground state of the Hamiltonian Eq. (11). For this state, the densities are found to be zero for all the \( n \)-strings with \( n = 2, 3, \ldots \) and 1-holes\(^2\). The system Eq. (29) reduces to the following simple integral equation for \( n = 1 \):
\[
a_1(\lambda) + a_1(\lambda - \omega) = \rho_1(\lambda) + \int_{-\infty}^{\infty} T_{11}(\lambda - \mu) \rho_1(\mu) d\mu.
\]
(37)

Its solution
\[
\rho_1(\lambda) = \frac{1}{2 \cosh \pi \lambda} + \frac{1}{2 \cosh \pi (\lambda - \omega)},
\]
(38)

and the corresponding solution to (32)
\[
F_1(\lambda) \rho_1(\lambda) = \frac{1}{2 \cosh \pi (\lambda - \omega)}
\]
(39)
can be found by the Fourier transform. The integrals in (33) can be easily transformed to the following expression for the NNN expectation value:
\[
\xi(\omega) = \langle \mu \rangle |\bar{\sigma}_n \bar{\sigma}_{n+2} - 1 |\mu\rangle = \frac{3\omega^2 + 1}{\omega^2} I(\omega) - \frac{\omega^2 - 1}{\omega^2} I(0) - \frac{\omega^2 + 1}{\omega} \partial_\omega I(\omega),
\]
(40)
where $I(\omega)$ is the integral which can be expressed via Digamma functions, $\psi$, as

$$I(\omega) = \int_{-\infty}^{\infty} \frac{dx}{(x^2 + 1/4) \cosh \pi(x - \omega)}$$

$$= \psi(1 + i\frac{\omega}{2}) - \psi(1 - i\frac{\omega}{2})$$

$$+ \psi(1 + i\frac{\omega}{2}) - \psi(1 - i\frac{\omega}{2}).$$

(41)

We see that though the translational invariance $n \to n + 1$ is broken, the vacuum expectation value of the NNN exchange operator does not depend on the site parity. Up to the sign factor, the same is valid for the triple interaction terms: $\langle \vec{\sigma}_{2k}(\vec{\sigma}_{2k+1} \times \vec{\sigma}_{2k+2}) = -\langle \vec{\sigma}_{2k-1}(\vec{\sigma}_{2k} \times \vec{\sigma}_{2k+1})$.

In the limit $\omega \to 0$, from Eq. (40), we recover the known result for the expectation value of NNN exchange operator of Heisenberg XXX isotropic chain,

$$\langle \vec{\sigma}_n \vec{\sigma}_{n+2} \rangle = 1 - 16 \log(2) + 9\zeta(3).$$

(42)

This was calculated from the ground state energy of the Hubbard model in Ref. 14. We present the function $\xi(\omega)$ in Fig. 1.

The chiral-spin order parameter $\langle \{\mu\} | \vec{\sigma}_n(\vec{\sigma}_{n+1} \times \vec{\sigma}_{n+2}) | \{\mu\} \rangle$ is also important, as it defines the measure of chirality of the state. Substituting the densities $\rho$ and $F$ for the ground state, Eqs. (38) and (39), into Eq. (35), we obtain

$$\chi(\omega) = (-1)^n \langle \vec{\sigma}_n(\vec{\sigma}_{n+1} \times \vec{\sigma}_{n+2}) \rangle$$

$$= \left[ \frac{2}{\omega} I(0) - \frac{2 + 4\omega^2}{\omega} I(\omega) - (1 + \omega^2) \partial_\omega I(\omega) \right].$$

(43)

This function is plotted in Fig. 2. We see a perfect match between our plot and the numerical simulations of Ref. 12.

In conclusion, let us briefly comment on the possibility of extension of the developed method to the third neighbor correlation functions, in particular of the type, $\langle \vec{\sigma}_n \vec{\sigma}_{n+3} \rangle$. For this case one has to increase the level of inhomogeneity of the model by introducing two different shifts of the spectral parameter and consider the following monodromy matrix

$$\Theta(\lambda; \omega_1, \omega_2) = L_{3N,a}(\lambda)L_{3N-1,a}(\lambda - \omega_1)L_{3N-2,a}(\lambda - \omega_2)$$

$$\cdots L_{a}(\lambda)L_{2,a}(\lambda - \omega_1)L_{1,a}(\lambda - \omega_2),$$

(44)

which is defined on the lattice with $3N$ sites. With this construction, one again has an integrable model with commuting family of transfer matrices, but, contrary to case considered above, we will have now three local Hamiltonian operators. It is straightforward to derive their explicit forms, which are rather cumbersome and we don’t bring them here. These operators contain different products of spins residing on four neighboring sites, including, e.g., the combination $\vec{\sigma}_n \vec{\sigma}_{n+3}$. The number of quasi-shift operators will be also three instead of the two as in Eq. (10). It is plausible to think that one can use relations analogous to Eqs. (13) - (20) in order to extract contributions of different summands out of the local Hamiltonian operators, at least in the homogeneous limit, $\omega_1 = \omega_2 = 0$. These investigations may constitute separate article.
