ABSTRACT

We report the first detection in space of the single deuterated isotopologue of methylcyanoacetylene, $\text{CH}_2\text{DC}_3\text{N}$. A total of 15 rotational transitions, with $J = 8-12$ and $K_a = 0$ and 1, were identified for this species in TMC-1 in the 31.0-50.4 GHz range using the Yebes 40m radio telescope. The observed frequencies were used to derive for the first time the spectroscopic parameters of this deuterated isotopologue. We derive a column density of $(8 \pm 0.5) \times 10^{13} \text{cm}^{-2}$. The abundance ratio of $\text{CH}_2\text{DC}_3\text{N}$ to $\text{CH}_2\text{DC}_3\text{N}$ is $\sim 22$. We also theoretically computed the principal spectroscopic constants of $^{13}$C isotopologues of $\text{CH}_2\text{DC}_3\text{N}$ and $\text{CH}_2\text{DC}_3\text{N}$ and those of the deuterated isotopologues of $\text{CH}_2\text{DC}_3\text{H}$ for which we could expect a similar degree of deuteration enhancement. However, we have not detected either $\text{CH}_2\text{DC}_3\text{H}$ or $\text{CH}_2\text{DC}_3\text{D}$, nor any $^{13}$C isotopologues. The different observed deuterium ratios in TMC-1 are reasonably accounted for by a gas-phase chemical model where the low temperature conditions favour deuteron transfer through reactions with $\text{H}_2\text{D}^+$. 

Key words. Astrochemistry — ISM: molecules — ISM: individual (TMC-1) — line: identification — molecular data

1. Introduction

Deuterium fractionation is a well-known process in the dense interstellar medium that can occur both in the gas phase and on the surfaces of dust particles. This process allows deuterated isotopic species of interstellar molecules to reach abundances much higher than the D/H elemental abundance ratio ($1.5 \times 10^{-5}$ Linsky 2003). The high efficiency of deuterium fractionation allows deuterated species to achieve abundances as high as 30-40 % relative to the parent species, as occurs with HDCS (Marcelino et al. 2005) and CH$_2$DOH (Parise et al. 2006). Hence, deuterated isotopologues of abundant interstellar molecules make a significant contribution to the spectral richness of line surveys. This makes the astronomical identification of these isotopologues of utmost importance, not only to gain knowledge on their molecular formation pathways or how deuterium fractionation works, but also to assign unidentified features in line surveys.

Very sensitive broadband line surveys of astronomical sources can now be achieved thanks to new technical developments in radio astronomy. These surveys have boosted the number of new molecular identifications in recent years because weak lines arising from low-abundance species and from low-dipole moment species can be now easily detected (Agúndez et al. 2021a; Cernicharo et al. 2021a,b,c). The negative counterpart of this high sensitivity is the huge number of new lines that populate the survey, including isotopologues and vibrationally excited states, in warm environments of well-known species. Hence, discovering spectral features of new molecules requires a previous detailed analysis of the spectral contribution of known species.

Methylcyanoacetylene, $\text{CH}_2\text{C}_3\text{N}$, also known as cyanopropyne or methylpropionitrile, has been detected with high abundance in the cold dark cloud TMC-1 (Broten 1984) and more recently by Marcelino et al. (2021) using a high-sensitivity line survey on TMC-1 gathered with the Yebes 40m radio telescope (see e.g. Cernicharo et al. 2021d). Hence, the deuterated isotopologues of $\text{CH}_2\text{C}_3\text{N}$ are good candidates to be observed in this source using the same line survey. We have already detected other singly deuterated isotopologues of species such as $\text{CH}_3\text{CN}$, $\text{CH}_3\text{CCH}$, $\text{c-C}_3\text{H}_2$, $\text{C}_2\text{H}_2$, $\text{H}_2\text{C}_2\text{N}$, $\text{H}_2\text{CCN}$, $\text{HC}_3\text{N}$, and $\text{HCSN}$ (Cabezas et al. 2021).

In this letter we report the identification of spectral lines of the deuterated species $\text{CH}_2\text{DC}_3\text{N}$ in TMC-1. Our search for this molecule is based on the change in the rotational parameters of $\text{CH}_2\text{C}_3\text{N}$ produced by the H-D exchange, which have been obtained by ab initio calculations. The derived deuterium ratios are compared to an extended chemical model including the related deuterated compounds.

2. Observations

The Q-band observations of TMC-1 ($\delta_{J2000} = 4^h41^m41.9^s$ and $\delta_{J2000} = +25^\circ41’27.0’’$) described in this work were performed in several sessions between November 2019 and April 2021. They were carried out using a set of new receivers, built within the Nanocosmos project$^1$, and installed at the Yebes 40m radio telescope.

$^*$ Based on observations carried out with the Yebes 40m telescope (projects 19A003, 20A014, and 20D15). The 40m radiotelescope at Yebes Observatory is operated by the Spanish Geographic Institute (IGN, Ministerio de Transportes, Movilidad y Agenda Urbana).

$^1$ https://nanocosmos.iff.csic.es/
The Q-band receiver consists of two high-electron-mobility transistor cold amplifiers covering the 31.0–50.4 GHz band in the horizontal and vertical polarizations. The receiver temperature varies from 22 K at 32 GHz to 42 K at 50 GHz. The spectrometers formed by $2 \times 8 \times 2.5$ GHz fast Fourier transforms (FFTs) provide a spectral resolution of 38.15 kHz and cover the whole Q band in both polarizations. The receivers and the spectrometers are described in Tercero et al. (2021).

Different frequency coverages were observed, 31.08-49.52 GHz and 31.98-50.42 GHz, which permitted us to check that no spurious ghosts were produced in the down-converson chain when the signal coming from the receiver was downconverted to 1–19.5 GHz, and was then split into eight bands with a coverage of 2.5 GHz, each of which was analysed by the FFTs.

The observing procedure used was the frequency switching mode, with a frequency throw of 10 MHz or 8 MHz (see e.g. Cernicharo et al. 2021a,d,e,f). The intensity scale, or antenna temperature ($T_a$), was calibrated using two absorbers at different temperatures and the atmospheric transmission model ATM (Cernicharo 1985; Pardo et al. 2001). Calibration uncertainties of 10% were adopted, based on the observed repeatability of the line intensities between different observing runs. All data were analysed using the GILDAS package.

### 3. Results

The identification of most of the features from our TMC-1 Q-band line survey was done using the MADEX code (Cernicharo 2012) and the CDMS and JPL catalogues (Müller et al. 2005; Pickett et al. 1998). Nevertheless, many lines remain unidentified. Among these U lines we found a series of five lines with a harmonic relation 8:9:10:11:12 between them. This series of lines could be fitted using a Hamiltonian for a linear molecule with a harmonic relation 8:9:10:11:12 between them. All the observed lines, shown in Table 1 and Fig. 1, were analysed using an asymmetric rotor Hamiltonian in the FITWAT code (Cernicharo et al. 2018) to derive the rotational and centrifugal distortion constants shown in Table 2. With the available data we could not determine the $A$ rotational constant, which was kept fixed to the ab initio value, as explained below.

The identification of the spectral carrier is first based on the following points: (i) the molecule is a closed-shell species without any appreciable fine or hyperfine interaction or large amplitude motion; (ii) the determined values for $B$ and $C$ constants indicate that the molecule is a very slightly asymmetric rotor, because $B$ and $C$ values are similar; and (iii) the $(B+C)/2$ value (1989.43 MHz, corresponding to the rotational constant of the close symmetric species) is smaller than that of $^{12}$C$_2$S (2295.29 MHz), but larger than that of $^{13}$C$_2$S (1344.72 MHz), which indicates that the molecule should contain four C atoms and one atom heavier than C. With these assumptions, we excluded species with four carbon atoms and a sulfur atom because they are too heavy. Species containing four carbon atoms and oxygen, like $^{12}$CO$_2$ (Kohguchi et al. 1994) and $^{13}$CO$_2$ (Brown et al. 1979), are rejected as candidates because they are too light ($B=2279.914$ MHz and $(B+C)/2=2153.75$ MHz, respectively) and other species derived from them are too heavy or are open-shell species. Molecules with four carbon atoms and nitrogen could be good candidates. The HC$_4$N molecule (Tang et al. 1999) has a rotational constant $B=2302.398$ MHz, and $(B+C)/2$ values for the cationic species $^{13}$C$_2$NH$^+$ and $^{13}$C$_2$CN$^+$ in their $^{13}$C$_2$CN ground states have been calculated to be $2159.3$ MHz and $2194.7$ MHz, respectively (CCSD/cc-pVTZ level of theory; Čížek 1969; Dunning 1989). The next member of this hydrogen addition progression is CH$_3$CN, whose rotational constant is 2065.74 MHz, very close to our $(B+C)/2$ value. This prompted us to think that the spectral carrier could be the deuterated isotopologue CH$_2$DC$_N$, an asymmetric rotor, because the H-D interchange breaks the $C_3$ symmetry of CH$_3$CN.

We performed geometry optimization calculations for CH$_3$CN and CH$_2$DC$_N$ in order to estimate the isotopic shift on the rotational constants for the CH$_3$CN-CH$_2$DC$_N$ system. Using the ratio of experimental to theoretical values is the most common method of predicting the expected experimental rotational constants for an isotopic species of a given molecule when the rotational constants for its parent species are known. Hence, we employed the CCSD/cc-pVTZ level of theory (Čížek 1969; Dunning 1989), which reproduces well the $B$ rotational constant.

### Table 1. Observed line parameters for CH$_2$DC$_N$ in TMC-1.

| $(J_{K_a,K_c})_{h}$ | $v_{abs}$ | $J T_a dv^b$ | $\Delta v^c$ | $T_a^d$ |
|-------------------|-----------|--------------|--------------|---------|
| $(0,0,0)$ | 31977.891 | 2.08530.12 | 0.044015 | 2.5423 |
| $(2,1,0)$ | 31858.913 | 2.00803.12 | 0.038015 | 2.5423 |

Notes. (a) Observed frequencies towards TMC-1 for which we adopted a $v_{LSR}$ of 5.83 km s$^{-1}$ (Cernicharo et al. 2020a,b,c). The frequency uncertainty 10 kHz. (b) Integrated line intensity in mK km s$^{-1}$. (c) Line width at half intensity derived by fitting a Gaussian function to the observed line profile (in kHz).

### Table 2. Observationally derived and theoretical spectroscopic parameters (in MHz) for CH$_2$DC$_N$.

| Constant | Space | Ab initio |
|----------|-------|-----------|
| $A$ | 120120.70 | 120120.70 |
| $B$ | 199349.107(593) | 1993.53 |
| $C$ | 1985363112(657) | 1985.74 |
| $A_0$ | 9.107(280) $10^{-3}$ | - |
| $D_0$ | 1.4767(249) $10^{-3}$ | - |
| $e_{mc}^d$ | 13.6 | - |
| $I_{mc}$ | 0/1 | - |
| $N_0^e$ | 15 | - |

Notes. (a) Fit to the lines of CH$_3$CN; observed in TMC-1. (b) CCSD/cc-pVTZ level of theory. Scaled values using as reference CH$_3$CN; see text. (c) Fixed to the calculated value. (d) Standard deviation of the fit in kHz. (e) Number of lines included in the fit.

Fig. 1. Observed lines of CH$_2$DC$_3$N in TMC-1 in the 31.0-50.4 GHz range. Frequencies and line parameters are given in Table 1. Quantum numbers for the observed transitions are indicated in each panel. The red line shows the synthetic spectrum computed for a rotational temperature of 8 K and a column density of $8 \times 10^{10}$ cm$^{-2}$ (see text). The additional components seen in the synthetic spectrum close to the $K_a = 0$ components are the $K_a = 2$ rotational transitions. Blanked channels correspond to negative features created in the folding of the frequency switching data. The label ‘U’ corresponds to features above 4σ.

Methyldiacetylene (CH$_3$C$_4$H) is 7.5 times more abundant than, and lines have similar intensities to, CH$_3$C$_3$N (Marcelino et al. 2021; Cernicharo et al. 2021c). Hence, it is straightforward to think that spectral signatures of the deuterated species of CH$_3$C$_4$H could also be detected in our line survey. We followed the same strategy used for CH$_2$DC$_3$N to predict the transition frequencies of CH$_2$DC$_4$H. Laboratory values are available for CH$_3$C$_4$D (Heath et al. 1955). We carried out geometry optimization calculations for CH$_3$C$_4$H. The rotational constants obtained for CH$_2$DC$_3$H are shown in Table 3. We found only

for CH$_3$C$_3$N, 2058.0 MHz versus 2065.74 MHz. The theoretical values for the rotational constants of CH$_2$DC$_3$N were then scaled using the experimental/theoretical ratio obtained from CH$_3$C$_3$N, and the results are shown in Table 2. As can be seen, the predicted values for CH$_2$DC$_3$N perfectly match those derived from our fit, which allows us to conclude that the spectral carrier of our lines is CH$_2$DC$_3$N. It should be noted that the calculations provide the equilibrium values for the rotational constants ($A_e$, $B_e$, and $C_e$), while the experimental values are the ground state rotational constants ($A_0$, $B_0$, and $C_0$). Even though the equilibrium rotational constants differ slightly from the ground state constants, we can assume similar discrepancies for CH$_3$C$_3$N and CH$_2$DC$_3$N, and thus that the estimated constants for CH$_2$DC$_3$N are essentially unaffected.

Methyldiacetylene (CH$_3$C$_4$H) is 7.5 times more abundant than, and lines have similar intensities to, CH$_3$C$_3$N (Marcelino et al. 2021; Cernicharo et al. 2021c). Hence, it is straightforward to think that spectral signatures of the deuterated species of CH$_3$C$_4$H could also be detected in our line survey. We followed the same strategy used for CH$_2$DC$_3$N to predict the transition frequencies of CH$_2$DC$_3$H. Laboratory values are available for CH$_3$C$_4$D (Heath et al. 1955). We carried out geometry optimization calculations for CH$_3$C$_4$H. The rotational constants obtained for CH$_2$DC$_3$H are shown in Table 3. We found only
two lines at the predicted transition frequencies corresponding to 8.0–7.0 and 9.0–8.0 with intensities of ~1 mK. Other lines predicted in the frequency range of the line survey are below the present sensitivity. We consider that the deuterated isotopologue of CH$_3$C$_2$H is not detected so far (see below). The deuteration of this species is discussed in the following section.

Considering the intensity of the CH$_3$C$_2$N and CH$_3$C$_2$H lines in our line survey, we expected to observe the $^{13}$C isotopologues as well. The frequency transitions for these species were predicted using the rotational constants from Table 3, which were obtained using the same procedure employed for the CH$_2$DC$_3$N isotopic species. However, we could not find spectral signatures for any of these species around the predicted frequencies.

The column density of CH$_2$DC$_3$N was derived from a rotational diagram analysis of the observed intensities. We assumed a source of uniform brightness with a radius of 40" (Fossé et al. 2001). We derive $T_R=8.0\pm0.5$ K and N(CH$_2$DC$_3$N)=$(8.0\pm2.4)\times10^{10}$ cm$^{-2}$. As shown in Fig. 1, the agreement between the synthetic spectrum and the observations is excellent. The column density is not very sensitive to the adopted value of the rotational temperature between 6 and 10 K. For the normal isotopologue Marcelino et al. (2021) derived a rotational temperature for the $A$ and $E$ species of 6.7±0.2 K and of 8.2±0.6 K, respectively. They derived a total column density for CH$_3$C$_3$N of (1.74±0.1)×10$^{12}$ cm$^{-2}$. Hence, the CH$_3$C$_3$N/CH$_2$DC$_3$N abundance ratio is 22±2.

The column density of CH$_3$C$_3$H has been derived by Cernicharo et al. (2021c) to be (1.3±0.04)×10$^{13}$ cm$^{-2}$. Assuming the same rotational temperature for CH$_2$DC$_3$H as for the main isotopologue (Cernicharo et al. 2021c), we derive a 3σ upper limit to its column density of 3.7×10$^{14}$ cm$^{-2}$. Therefore, the CH$_3$C$_3$H-to-CH$_2$DC$_3$H abundance ratio is ≥35 (3σ). For the deuterated species CH$_3$C$_2$D, for which laboratory spectroscopy is available (Heath et al. 1955), we derive a 3σ upper limit to its column density of 9×10$^{10}$ cm$^{-2}$. Hence, N(CH$_3$C$_3$H)/N(CH$_3$C$_3$D)≥144.

### 4. Chemical modelling

We further investigate the chemical processes leading to deuterium insertion in methlycyanocacetylene and methylidyacetylene by extending our previous study on H$_2$CCN and HDCCN (Cabzes et al. 2021). We only consider gas-phase mechanisms that allow quantitative predictions based on some experimental measurements and theoretical studies. The chemistry of the different C$_2$H$_3$N and C$_2$H$_4$ isomers has been discussed recently in Cernicharo et al. (2021c) and Marcelino et al. (2021), respectively, in relation with their detection in TMC-1. These two chemical families are tightly linked to the chemistry of methylacetylene, CH$_3$CCH, and its isomer allene, CH$_2$C=CH$_2$:

\[
\begin{align*}
\text{CN} + \text{CH}_3\text{CCH} & \rightarrow \text{CH}_3\text{C}_2\text{N} + \text{H}, \\
& \rightarrow \text{HCN} + \text{CH}_2\text{CCH}, \\
& \rightarrow \text{HC}_3\text{N} + \text{CH}_3; \\
\text{C}_2\text{H}_3 + \text{CH}_3\text{CCH} & \rightarrow \text{CH}_3\text{C}_2\text{H} + \text{H}, \\
& \rightarrow \text{H}_2\text{CCCHCCH} + \text{H},
\end{align*}
\]

whereas

\[
\begin{align*}
\text{CN} + \text{CH}_3\text{CCH}_2 & \rightarrow \text{CH}_2\text{CCHCN} + \text{H}, \\
& \rightarrow \text{HCCCHCN} + \text{H}; \\
\text{C}_2\text{H}_3 + \text{CH}_3\text{CCH}_2 & \rightarrow \text{CH}_3\text{C}_2\text{H} + \text{H}, \\
& \rightarrow \text{H}_2\text{CCCHCCH} + \text{H}.
\end{align*}
\]

Considering the deuterated analogues of these reactions introduces diverse questions, for example whether the CN reactions proceed without changing the methyl radical or lead to some scrambling of the hydrogen atoms in a quasi-stationary intermediate followed by different reaction channels. The first assumption would lead to the reactions

\[
\begin{align*}
\text{CN} + \text{CH}_3\text{DCCCH} & \rightarrow \text{CH}_2\text{DCCN} + \text{H}, \\
\text{CN} + \text{CH}_3\text{CCD} & \rightarrow \text{CH}_3\text{C}_2\text{D} + \text{H}.
\end{align*}
\]

whereas the second option would introduce an additional reaction channel:

\[
\begin{align*}
\text{CN} + \text{CH}_3\text{DCCCH} & \rightarrow \text{CH}_3\text{C}_2\text{D} + \text{H}, \\
\text{CN} + \text{CH}_3\text{CCD} & \rightarrow \text{CH}_3\text{C}_2\text{D} + \text{H}.
\end{align*}
\]

The case of the reactions involving C$_2$H (C$_2$D) is even more uncertain as an additional H(D) atom is involved, which leads to a

\]

Similar questions arise in the deuteriation mechanisms involving deuteron transfer initiated by reactions with abundant deuterated molecular ions such as H_2D^+ and DCO^+. As an example, the products of the H_2D^+ + CH_3CN reaction could be CH_3CND^+ or H_2, if the reaction proceeds directly, or also CH_3DCN NH^+ + H_2, if an intermediate complex is formed. The following step in forming deuterated methycyanocacetylene entails dissociative recombination of the molecular ion, where an additional question arises on the branching ratios of the reaction CH_3DCN NH^+ + e^- \rightarrow CH_3DCN + H and/or \rightarrow CH_3CN + D. These few examples show the multiple issues that emerge when analysing the potential chemical processes at work. We considered two different approaches. In case A we assume that the methyl radical and its deuterated form keep their structure (e.g. as in reactions 1, 2, 5, 6, 8), whereas case B involves a scrambling of the H and D atoms followed by the formation of the different products (e.g. as in reactions 3, 4, 7, 9, 10). These hypotheses are implemented in a chemical model including 320 species and more than 9000 gas-phase reactions built from previous studies (Cabezas et al. 2021; Agúndez et al. 2021b). We display in Table 4 the corresponding steady-state ratios obtained in a model adapted to TMC-1 conditions, n(H_2)= 4 \times 10^{10} cm\(^{-3}\), T=10 K, \(\zeta = 1.5 \times 10^{-17}\) s\(^{-1}\), as in Cabezas et al. (2021). We first note the significant sensitivity of the deuterium ratio for CH_3C_H and CH_3C_H to the reactivity assumptions. A low deuterium ratio, close to the observed value of CH_3C_H, is favoured in the full scrambling approximation. The upper limits found for CH_3C_H/CH_2C_H and CH_3C_H/CH_3C_D, on the other hand, are better reproduced when reactions 5, 6, and 8 are the only channels in the C(2D) reactions. Whereas the other observed deuteration ratios are reasonably reproduced within a factor of 2, a significant discrepancy is still obtained for methycacetylene, CH_3C_C, as already noted in Cabezas et al. (2021) and Agúndez et al. (2021b). This feature arises because the reaction of CH_3C_C with H_2 (and supposedly H_2D^+) leads to the break up of CH_3C_C into c-C,H_3 and I-C,H_2 (c-C,H_2D^+ and I-C,H_2D^+) rather than to C,H_3^+ or C,H_2D^+ (CH_3C_C^+, CH_3DCCH_H^+, CH_3CCHD^+), as found in the experimental study of Milligan et al. (2002). We did not try to include additional deuterium exchange reactions, in the absence of any theoretical or experimental information.

We conclude this section by acknowledging the possible gas-phase deuteration mechanisms of cyanomethacetylene mediated by deuteron transfer reactions with species such as H_2D^+ and DCO^+, among other deuterated cations in low-temperature conditions, but point out the substantial uncertainties involved in the different possible reactions, so that a detailed comparison between observations and chemical modeling appears elusive. A theoretical analysis of the intermolecular interaction potentials involved in the approach of the different reactants would help to validate the various reaction mechanisms.

\[3\] The channel CH_3C_H NH^+ + HD is present in both cases as well.\[4\] The elemental values (i.e. O/H = 8 \times 10^{-6}, C/O = 0.75, N/O= 0.5) correspond to a carbon-rich environment.

5. Conclusions

We have detected and unambiguously identified CH_3DC_N, a new deuterated compound, in TMC-1 thanks to highly sensitive space observations of 15 different transitions and to the associated theoretical considerations and quantum mechanical calculations. Spectroscopic constants are also provided for that compound and the ^13C and ^15N substitutes, which should help to study those species in the laboratory as well. The observed deuterium fractions are further compared to a gas-phase model, which, despite significant uncertainties, accounts within a factor of two for the different values, except for CH_3C_C. Further experimental or theoretical studies are welcome.
