Abstract
Fossil fuel is known to increase greenhouse gas emission which has resulted in serious environmental consequences. This study was designed to determine bioethanol production from pineapple(a fructogenic waste) and cassava (a glucogenic waste). It was also designed to allow a comparative analysis of pure ethanol with ethanol produced from the two food wastes with a view to generate an alternative fuel source. The parameters evaluated were the volume of bioethanol per 100g of waste, percentage (%) purity of bioethanol produced, pH and auto ignition temperature of bioethanol produced. The values obtained were analyzed using the unpaired student’s t-test where appropriate to determine if there are any significant differences in pure ethanol values for those parameters. The result showed that relative to the pure ethanol(control), the auto ignition temperature of ethanol produced from the cassava (Manihot esculenta) and pineapple (Ananas comosus) wastes were significantly \((p≤0.05)\) high. The autoignition temperature of ethanol produced from pineapple waste was slightly higher when compared to bioethanol from cassava waste but it was not statistically significant \((p>0.05)\). The volume of ethanol produced from cassava waste was slightly lower \((p>0.05)\), when compared to the volume of the same parameter in the pineapple waste. There was a significant \((p≤0.05)\) decrease in pH of ethanol produced from pineapple waste when compared to that from cassava waste. The % purity of the bioethanol produced from pineapple waste was higher \((p>0.05)\) when compared to that from the cassava waste. The autoignition temperature of the blend of produced bioethanol was slightly reduced \((p>0.05)\) when compared to the autoignition temperatures of individual ethanol from separate waste. But, relative to the pure ethanol utilized as a control in this study, the autoignition temperature of the blend was significantly \((p≤0.05)\) high. Finally, it was observed that bioethanol obtained from cassava waste (a glucogenic energy source) produced a lower yield in volume with a 15.8 v/100g (ml) value while its fructogenic counterpart (pineapple waste) exhibited a slightly lower autoignition temperature effect \(33°C\). The autoignition temperature of the waste blend (Cassava-Pine) was 30°C when compared to each waste source alone. A combination of both cassava and pineapple waste yielded better fuel properties and its campaigned in this study for use in the production of biofuel.

Key words: Bioethanol production, pineapple waste, cassava waste, Warri.

Introduction
Fossil fuel is reported to have grave deleterious effects on the environment [1]. This is due to its propensity to increase the level of carbon (IV) oxide \(\text{CO}_2\), a greenhouse gas, directly responsible for global warming [2]. Bioethanol produced from renewable sources is gaining global recognition due to the continuous depletion of fossil fuel [3]. Food products like corn and sugar cane containing fermentable sugars are utilized all over the world for the production of bio-fuel [4]. There are also reports suggesting that ethanol produced via fermentation accounts for approximately 95% bioethanol production [3]. In Nigeria, tons of foods and fruits wastes are generated all year round owing to poor storage facilities. This study was therefore designed to comparatively evaluate bioethanol
production from pineapple (*Ananas comosus*) and cassava (*Manihot esculenta*) waste within Warri and environs with a view to finding out the suitability of the use of these wastes as raw materials for alternative fuel sources to fossil fuels.

**Materials and methods**

**Yeast and treatment of yeast source**

The treatment of yeast in this study was done according to the method described by [5]. Three gram (3g) of STK Royal Instant Dry Yeast, a product of STK Industry Limited Lagos, containing (*S. cerevisiae*) was dissolved in 1000ml deionized water; the mixture was heated in a water bath to 40°C to allow for complete dissolution.

**Saccharification of Cassava Waste**

Cassava waste was collected rinsed, blended and converted to sugar according to the method described by [6, 7] with a slight modification as described. Cassava blend (20g) was pretreated with 10 ml of 2% w/w tetraoxosulphate (VI) acid. The mixture was then treated with an enzyme mixture preparation (containing α-amylase) and allowed to stand for 6hrs. The filtrate was then inoculated with the yeast strain (*S. cerevisiae*)

**Fermentation of Cassava and Pineapple (*Ananas comosus*) extract**

The method used in the production of bioethanol in the study was the fermentation method described by [8, 9] using the commercially available yeast, *Saccharomyces cerevisiae* NCYC 2826 strain. 100g of pineapple and cassava wastes obtained from Hausa Quarters, Igbudu Market Warri were packed in separate dark polyethylene bucket with a lid and allowed to stand for 10d. The wastes were then blended using a MX-151SP2 Panasonic blender. The blend was filtered using a Whatman 20 Cellulose Filter paper. The filtrate was transferred into a black polyethylene container, and 3ml of the yeast solution was introduced into the container and the pH was adjusted to 5.8 using 5M NaOH and 1M HCl for upward and downward adjustment respectively. The black polyethylene bottle was put in an incubator at 30°C for 72hrs.

**Purification of ethanol produced**

Ethanol produced was purified by table distillation method described by American Standard for Testing and Material (ASTMD86).

**Determination of Auto-ignition temperature**

This was done according to the ASTM E 659 method modified by [10]. Bioethanol sample was placed in a 500-millilitre flask placed in a temperature-controlled oven the initial temperature of ignition when exposed to a heat flame was recorded as the auto ignition temperature (ASTM E659).

**Statistical analysis**

All data obtained were analyzed using the student’s *t* test of the SPSS 16.0 statistical package and *p*≤0.05 was considered significant. The results were expressed as mean±SD.

**Results**

The result of the relationship between pH indices of bio-ethanol produced from cassava and pineapple are expressed in Figure 1.0. The pH value of cassava (*Manihot esculenta*) waste in this study was slightly (P>0.05) higher when compared to the pH of pineapple. The pH value of the bioethanol of the blend was enhanced when compared with the pH of bioethanol from cassava or pineapple alone. The pH value of the blend (Cassava-pine) was low when compared with the pH of the standard ethanol.
Figure 1.0: pH of bioethanol from different waste biomass.

The result of the relationship between volume of ethanol produced from cassava and pineapple are expressed in Figure 2.0. The volume of bioethanol from cassava *(Manihot esculenta)* waste in this study was lower (*p* > 0.05) when compared to the volume of ethanol from pineapple waste and also when compared with the volume of bioethanol produced from the blend of cassava and pineapple.

Figure 2.0: Bioethanol from waste biomass in Warri.

The result of the percentage purity of bioethanol produced from cassava and pineapple waste biomass from Warri are expressed in Figure 3.0. The % purity of bioethanol from cassava *(Manihot esculenta)* waste in this study was the lowest (62%) when compared to the values obtained for pineapple, cassava-pine and pure ethanol with values of 76%, 80.10% and 98% respectively.
Figure 3.0: Percentage purity of bioethanol from different biomass in Warri.

The autoignition temperatures of bioethanol from cassava and pineapple waste are expressed in Figure 4.0. The auto-ignition temperature of bioethanol produced from cassava was slightly high (P>0.05) when compared to the auto-ignition temperature of pineapple waste and the blend (cassava-pine). The auto-ignition temperature of cassava, pineapple and cassava-pine were significantly (P<0.05) high relative to the 13°C auto-ignition temperature of pure ethanol evaluated in this study.

Results and Discussion

The main purpose of this study was to evaluate ethanol production from glucogenic and fructogenic waste sources with a view to ascertain their suitability for use in biofuel production.

Studies showed that sucrose-containing materials simplify the ethanol production process, which could eventually lead to high yield [11]. Our result revealed a slight elevation in bioethanol from pineapple waste biomass when compared to its cassava counterpart. This study gives credence to the report of [12] but does not agree with the report of [13] who demonstrated that a glucogenic biofuel source produced a higher volume of bioethanol due to the high photosynthetic efficiency. In this study, the observed increase volume of bioethanol from cassava-pine blend may be due to high biomass of the cassava.

Autoignition temperatures are useful indicators of suitability of the material for production from previous term sugarcane. Energy Policy. 36(6): 2086-2097.

Conclusion

The waste biomass of cassava and pineapple may serve as a potential source of raw material for alternative energy by the presence of some indicators of a good fuel. This study therefore provides some scientific support for the utilization of food waste as an alternative fuel source. However, it is necessary to carry out some more comprehensive study of all the parameters use as indicators of a good fuel that were not captured in this study.

Substances with autoignition temperatures near and below ambient temperature have been proven to be excellent fuel sources. Low auto ignition temperature is associated with increased volatility of fuel [10]. In our present study, the autoignition temperature of bioethanol from pineapple was lower than that from cassava. This could be because the bioethanol from the fructogenic food source (pineapple) is slightly volatile than that from the glucogenic food source (cassava).
