Cardinal interpolation with general multiquadrics

Keaton Hamm · Jeff Ledford

Abstract This paper studies the cardinal interpolation operators associated with the general multiquadrics, \( \phi_{\alpha,c}(x) = (\|x\|^2 + c^2)^\alpha, \ x \in \mathbb{R}^d \). These operators take the form

\[
\mathcal{I}_{\alpha,c}y(x) = \sum_{j \in \mathbb{Z}^d} y_j L_{\alpha,c}(x - j), \quad y = (y_j)_{j \in \mathbb{Z}^d}, \quad x \in \mathbb{R}^d,
\]

where \( L_{\alpha,c} \) is a fundamental function formed by integer translates of \( \phi_{\alpha,c} \) which satisfies the interpolatory condition \( L_{\alpha,c}(k) = \delta_{0,k}, \ k \in \mathbb{Z}^d \). We consider recovery results for interpolation of bandlimited functions in higher dimensions by limiting the parameter \( c \rightarrow \infty \). In the univariate case, we consider the norm of the operator \( \mathcal{I}_{\alpha,c} \) acting on \( \ell_p \) spaces as well as prove decay rates for \( L_{\alpha,c} \) using a detailed analysis of the derivatives of its Fourier transform, \( \widehat{L}_{\alpha,c} \).

1 Introduction

The term cardinal interpolation refers to interpolation of data given at the integer lattice (or multi-integer lattice in higher dimensions). It was I. J. Schoenberg’s work on cardinal spline interpolation that brought about an intense study of the subject. Many avenues of study have been explored, including forming interpolation operators from translates of certain radial basis functions (RBFs). Works by Buhmann, Baxter, Riemenschneider, and Sivakumar [3, 7, 29](see also [28] and references therein) have explored many cardinal interpolation operators of this type. Some of the radial basis functions that have been considered are the Gaussian kernel, the thin plate spline, the Hardy multiquadric, and the inverse multiquadric.

Radial basis cardinal interpolation also enjoys a strong connection with classical sampling theory, as evidenced by much of the aforementioned literature. This connection continues to be explored in recent developments by the second author [23, 24], and by parts of this article. As this is one of the most interesting aspects of cardinal interpolation, we provide some of the motivation. Recall the one-dimensional Whittaker–Kotelnikov–Shannon Sampling Theorem, which states that a bandlimited function, \( f \), (say with band size \( \pi \)) can be recovered uniformly by the series \( \sum_{j \in \mathbb{Z}} f(j) \text{sinc}(x - j) \), where the sinc function is suitably defined so that it takes value 1 at the origin, and 0 at all the other integers. One observation about this series is that the sinc function decays slowly (as \( |x|^{-1} \)), and so to approximate the series by truncation for example, one would have to use quite a lot of data points of \( f \) to get a reasonable degree of accuracy.

However, there is a way of approximating the sinc series above: we seek to replace the sinc function with a so-called fundamental function (or cardinal function), \( L \), that preserves the property that \( L \) takes value 1 at the origin and 0 at all other integers. We then form a function

\[
\mathcal{I} f(x) = \sum_{j \in \mathbb{Z}} f(j) L(x - j).
\]

The trade-off here is that while \( \mathcal{I} f \) is not pointwise equal to the function \( f \), it does interpolate \( f \) at the integer lattice, and moreover, the fundamental function \( L \) may be constructed so that it decays much more rapidly than the sinc function. Precisely, one may construct a fundamental function from a given radial basis function, \( \phi \), which has the form

\[
L_\phi(x) = \sum_{j \in \mathbb{Z}} a_j \phi(x - j).
\]

In the case of the Gaussian kernel, \( g_\lambda(x) = e^{-\lambda|x|^2} \), the fundamental function decays exponentially, whereas the fundamental function for the Hardy multiquadric, \( \sqrt{|x|^2 + c^2} \), decays as \( |x|^{-5} \). So we give up the pointwise equality of the WKS Sampling Theorem in exchange for a series that converges more rapidly, while also ensuring that \( \mathcal{I} f \) is close to \( f \) in the \( L_2 \) norm.

This paper primarily considers the fundamental functions and cardinal interpolation operators associated with general multiquadrics, \( \phi_{\alpha,c}(x) = (\|x\|^2 + c^2)^\alpha \), which
have thus far only been considered for certain exponents \( \alpha \). Interpolation with fundamental functions has too long a history to recount here; however, [9] offers a good introduction using radial basis functions. Using Eq. 6 below as a starting point is especially popular since it allows one to solve problems in the Fourier transform domain. Many authors have used similar techniques for various radial basis functions. In [28–30], Riemenschneider and Sivakumar proved several results pertaining to the Gaussian. Multiquadric cardinal interpolation has been studied in a similar way by Buhmann and Micchelli [10], Baxter [3], Baxter and Sivakumar [4], Riemenschneider and Sivakumar [29], among others. Compactly supported radial basis functions have been studied by Buhmann [8] and Wendland [33].

The rest of the paper is laid out as follows. Section 2 provides the necessary preliminaries and a discussion of applications and calculations of the fundamental functions; Section 3 shows recovery results for cardinal interpolation of band-limited functions in any dimension via interpolants of the form discussed above. Section 4 contains decay rates and information about the univariate fundamental functions associated with the general multiquadrics for a broad range of exponents. In Section 5, we consider the cardinal interpolation operators acting on data in traditional sequence spaces and calculate decay rates, bounds on the operator norms, and also explore some convergence properties in terms of the parameter \( c \). Section 6 provides some interesting concrete examples based on the theoretical results from the previous section. Finally, Section 7 provides the technical proofs of the statements in Section 4.

2 Basic notions

If \( \Omega \subset \mathbb{R} \) is an interval, then let \( L^p(\Omega) \), \( 1 \leq p \leq \infty \), be the usual Lebesgue space over \( \Omega \) with its usual norm. If no set is specified, we mean \( L^p(\mathbb{R}) \). Similarly, denote by \( \ell^p(I) \) the usual sequence spaces indexed by the set \( I \); if no index set is given, we refer to \( \ell^p(\mathbb{Z}) \). We will use \( \mathbb{N}_0 \) to denote the natural numbers including 0. Let \( \mathcal{S} \) be the space of Schwartz functions on \( \mathbb{R}^d \), that is the collection of infinitely differentiable functions \( \phi \) such that for all multi-indices \( \alpha \) and \( \beta \),

\[
\sup_{x \in \mathbb{R}^d} |x^\alpha D^\beta \phi(x)| < \infty.
\]

The Fourier transform of a Schwartz function \( \phi \) is given by

\[
\hat{\phi}(\xi) := \int_{\mathbb{R}^d} \phi(x) e^{-i\langle \xi, x \rangle} dx, \quad \xi \in \mathbb{R}^d.
\] (1)

Thus the inversion formula is

\[
\phi(x) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} \hat{\phi}(\xi) e^{i\langle x, \xi \rangle} d\xi, \quad x \in \mathbb{R}^d.
\] (2)

In the event that these formulas do not hold, then the Fourier transform should be interpreted in the sense of tempered distributions. Recall that if \( f \) is a tempered distribution, then its Fourier transform is the tempered distribution defined by \( \{ \hat{f}, \phi \} = \{ f, \phi \}, \phi \in \mathcal{S} \).
Let $\alpha \in \mathbb{R}$ and $c > 0$ be fixed; then define the $d$-dimensional general multiquadric by
\[
\phi_{\alpha,c}(x) := \left( \|x\|^2 + c^2 \right)^{\alpha}, \quad x \in \mathbb{R}^d,
\] (3)
where $\| \cdot \|$ denotes the Euclidean distance on $\mathbb{R}^d$.

If $\alpha \in \mathbb{R} \setminus \mathbb{N}_0$, the generalized Fourier transform of $\phi_{\alpha,c}$ is given by the following (see, for example, [34, Theorem 8.15]):
\[
\hat{\phi}_{\alpha,c}(\xi) = \frac{2^{1+\alpha}}{\Gamma(-\alpha)} \left( \frac{c}{\|\xi\|} \right)^{\alpha + \frac{d}{2}} K_{\alpha + \frac{d}{2}}(c \|\xi\|), \quad \xi \in \mathbb{R}^d \setminus \{0\},
\] (4)
where
\[
K_v(r) = \frac{1}{2} \int_0^\infty e^{-r \cosh t} e^{vt} dt, \quad r > 0, \ v \in \mathbb{R}.
\] (5)
$K_v$ is called the modified Bessel function of the second kind. We note that both $\phi_{\alpha,c}$ and its Fourier transform are radial. It is also clear from the definition that $K$ is symmetric in its order; that is, $K_{-v} = K_v$ for any $v \in \mathbb{R}$. If $\alpha \in \mathbb{N}_0$, then the generalized Fourier transform of $\phi_{\alpha,c}$ involves a measure and so cannot be expressed as a function.

2.1 Fundamental functions

Now suppose that $\alpha \in \mathbb{R} \setminus \mathbb{N}_0$ is fixed. To define the fundamental function associated with the general multiquadric, we first define the following function
\[
\hat{L}_{\alpha,c}(\xi) := \frac{\hat{\phi}_{\alpha,c}(\xi)}{\sum_{j \in \mathbb{Z}^d} \hat{\phi}_{\alpha,c}(\xi + 2\pi j)}, \quad \xi \in \mathbb{R}^d.
\] (6)
We will see that $\hat{L}_{\alpha,c} \in L_1(\mathbb{R}^d)$, and so the function
\[
L_{\alpha,c}(x) := \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} \hat{L}_{\alpha,c}(\xi) e^{i(x,\xi)} d\xi, \quad x \in \mathbb{R}^d,
\] (7)
is well-defined and continuous. Furthermore, we will show that $L_{\alpha,c}$ is a fundamental function, also called a cardinal function, which means that
\[
L_{\alpha,c}(j) = \delta_{0,j}, \quad j \in \mathbb{Z}^d,
\] (8)
where $\delta_{i,j}$ is the Kronecker delta.

Additionally, $L_{\alpha,c}$ has the form
\[
L_{\alpha,c}(x) = \sum_{j \in \mathbb{Z}^d} c_j \phi_{\alpha,c}(x - j), \quad x \in \mathbb{R}^d.
\] (9)

Throughout the paper, we will use $A$ to denote an absolute constant due to the use of $c$ as the shape parameter of the multiquadric. The value of the particular constant may change from line to line, and we use subscripts to denote dependence on certain parameters when needed.
2.2 Evaluation of fundamental functions and applications

Interpolation schemes involving fundamental functions as in Eq. 9 have been studied for quite some time, and there are many aspects to the theory. For example, such methods enjoy applications to geoscience [13] and sampling theory [23]. Recently, investigations have considered interpolation via radial kernels on manifolds [20, 21]. For a Galerkin type method for solving PDEs using meshless interpolation on the sphere, see [27].

Given the widespread applications of radial basis function approximation, it is of import to the computational community to determine stable ways of evaluating the approximants. Consequently, there is a substantial literature dealing with accuracy and stability of different computational methodologies for radial basis function approximation. We do not claim to list all of these methods, but at least a sampling is in order. We note that approximating Eq. 9 is typically very difficult, especially if one dilates the lattice. One way around this is the use of indirect computational methods to approximate the RBF interpolant [14, 15] (for a discussion specifically related to multiquadrics, see [16]). Another technique involves a change of basis method [5], while work by Fasshauer and McCourt [12] uses an eigenfunction decomposition to provide stable reconstruction using Gaussians.

Another quite promising method has recently been considered in which so-called local Lagrange functions are used to approximate rather than the global ones [17, 19]. Many of these results revolve around the situation of interpolation at finitely many data sites, which is of a somewhat different nature than we are considering here. For the interested reader, we also mention that these methods of cardinal interpolation have, at their core, a deep connection to the classical spline theory instigated by Schoenberg (see [31] and references therein) and continued by many followers. The underlying principle is that many of the results in spline interpolation theory have natural analogues via RBFs, and the problem at hand may determine which method is more useful.

2.3 Examples

Here, we provide some brief illustrations of the fundamental functions we have mentioned above. Figure 1 shows the univariate fundamental function associated with the inverse multiquadric and the sinc function for comparison.

The fundamental function was calculated by truncating the series in Eq. 6 and using a fast Fourier transform (FFT) method to approximate \( L_{\alpha,c} \). The same method may be applied for the multivariate version, as Fig. 2 shows.

3 Recovery of multivariate bandlimited functions

When an interpolation scheme depends on a parameter, questions of convergence naturally arise. This question has been addressed by several authors. In [3], Baxter examines the Hardy multiquadric, while the Gaussian is studied in [30] by Riemenschneider and Sivakumar and in [18] by Hangelbroek, Narcowich, Madych, and
Fig. 1  Plots of sinc function and Fundamental function for the inverse multiquadric with $\alpha = -1/2$ with shape parameters $c = 1$ (left) and $c = 10$ (right)

Ward. In a more general context, ‘increasingly flat’ radial basis functions are the focus of Driscoll and Fornberg in [11], while the second author worked with ‘regular families’ of cardinal interpolants in [23].

In this section, we show that the result obtained by Baxter [3] holds not only for the traditional Hardy multiquadric (corresponding to $\alpha = 1/2$) but rather for all $\alpha \in \mathbb{R} \setminus \mathbb{N}_0$. We consider interpolation of bandlimited (or Paley-Wiener) functions in any dimension, and show that the cardinal interpolant converges to the function as the shape parameter $c$ tends to infinity. General multiquadrics were not considered for quite some time in this setting, but in [23] convergence results for cardinal interpolation of bandlimited functions were shown for a restricted range of exponents. However, the analysis there was of a more general nature, so here we show that a more specific analysis yields convergence results for the full range $\alpha \in \mathbb{R} \setminus \mathbb{N}_0$.

We note that the results of this section have very close ties to classical sampling theory, which studies the reconstruction of certain classes of signals from their

Fig. 2  Plots of 2-dimensional Poisson fundamental function $L_{-\frac{1}{2},1}$ (left) and sinc function (right) for comparison
discrete samples. As mentioned above, these considerations lead to alternative methods for approximating the sampling series given by the WKS Sampling Theorem for bandlimited signals.

Let \( d \) be the dimension, and \( \alpha \in \mathbb{R} \setminus \mathbb{N}_0 \) and \( c > 0 \) be fixed. It is evident from Eq. 4 that \( \hat{\phi}_{\alpha,c} \) does not change sign. Therefore, \( \hat{L}_{\alpha,c}(\xi) \geq 0 \) for all \( \xi \in \mathbb{R}^d \). From Eq. 6, it is also evident that \( 0 \leq \hat{L}_{\alpha,c}(\xi) \leq 1 \). To show that \( \hat{L}_{\alpha,c} \in L_1(\mathbb{R}^d) \) we begin with the following lemma.

**Lemma 1** Let \( R > r > 0 \), \( c > 0 \), and \( \alpha \in \mathbb{R} \setminus \mathbb{N}_0 \). Then

\[
|\hat{\phi}_{\alpha,c}(R)| \leq \left( \frac{R}{r} \right)^{-\alpha-\frac{d}{2}} e^{-c(R-r)} |\hat{\phi}_{\alpha,c}(r)|.
\]

**Proof** Defining \( \lambda := \lambda_{c,\alpha,d} := \frac{2\alpha}{\Gamma(-\alpha)} c^{\alpha+d/2} \), Eqs. 4 and 5 yield the following series of estimates:

\[
|\hat{\phi}_{\alpha,c}(R)| = |\lambda| R^{-\alpha-\frac{d}{2}} \int_0^\infty e^{-cR \cosh(t)} e^{(\alpha+d/2)t} dt
\]

\[
= |\lambda| \left( \frac{R}{r} \right)^{-\alpha-\frac{d}{2}} r^{-\alpha-\frac{d}{2}} \int_0^\infty e^{-c(R-r) \cosh(t)} e^{-cr \cosh(t)} e^{(\alpha+d/2)t} dt
\]

\[
\leq |\lambda| \left( \frac{R}{r} \right)^{-\alpha-\frac{d}{2}} r^{-\alpha-\frac{d}{2}} e^{-c(R-r)} \int_0^\infty e^{-cr \cosh(t)} e^{(\alpha+d/2)t} dt
\]

\[
= \left( \frac{R}{r} \right)^{-\alpha-\frac{d}{2}} e^{-c(R-r)} |\hat{\phi}_{\alpha,c}(r)|.
\]

The inequality comes from the fact that \( \cosh(t) \geq 1 \).

We note that if \( \alpha + \frac{d}{2} \geq 0 \), then \( (R/r)^{-\alpha-\frac{d}{2}} \leq 1 \), and so we have a purely exponential upper bound.

**Proposition 1** Let \( \alpha \in \mathbb{R} \setminus \mathbb{N}_0 \) and \( c > 0 \). Then \( \hat{L}_{\alpha,c} \in L_1(\mathbb{R}^d) \).

**Proof** First, choose an \( M > 0 \) large. Then since \( |\hat{L}_{\alpha,c}(\xi)| \leq 1 \) for all \( \xi \), we have that

\[
\int_{[-M,M]^d} |\hat{L}_{\alpha,c}(\xi)| d\xi \leq (2M)^d.
\]

Now we need to estimate

\[
I := \int_{\mathbb{R}^d \setminus [-M,M]^d} |\hat{L}_{\alpha,c}(\xi)| d\xi.
\]

To do this, we establish a pointwise estimate for \( \hat{L}_{\alpha,c}(\xi) \). Let \( \xi \in \mathbb{R}^d \setminus [-M,M]^d \) be fixed. Since \( M \) is large, there exists some \( k_\xi \in \mathbb{Z}^d \setminus \{0\} \) such that \( 2\pi \leq \|\xi + 2\pi k_\xi\| \leq 4\pi \). Additionally, there is some constant \( \gamma := \gamma_{\alpha,d} > 0 \) which depends
on $\alpha$ and $d$ such that if $cr \geq 1$, $K_{\alpha+\frac{d}{2}}(cr) \geq \gamma e^{-cr} (cr)^{-\frac{1}{2}}$ (see, for example, [34, Corollary 5.12]). Therefore, choose $M$ large enough so that for $\xi \in \mathbb{R}^d \setminus [-M, M]^d$, we have $c\|\xi\| \geq 1$. Then if $\lambda$ is the constant from Lemma 1,

$$
\left| \sum_{k \in \mathbb{Z}^d} \hat{\phi}_{\alpha,c}(\xi + 2\pi k) \right| \geq |\hat{\phi}_{\alpha,c}(\xi + 2\pi k_\xi)|
\geq \gamma |\lambda| \|\xi\| + 2\pi k_\xi \|^{-\alpha - \frac{d}{2}} e^{-c\|\xi\| + 2\pi k_\xi \| (c\|\xi\| + 2\pi k_\xi \|)^{-\frac{1}{2}}.}
$$

Now depending on the sign of $\alpha + \frac{d}{2}$, the above expression is minimized by plugging in $2\pi$ or $4\pi$ for $\|\xi + 2\pi k_\xi\|$ in the appropriate places. Consequently, there is a positive constant $D := D_{c,\alpha,d}$ such that

$$
\left| \sum_{k \in \mathbb{Z}^d} \hat{\phi}_{\alpha,c}(\xi + 2\pi k) \right| \geq D e^{-4\pi c}.
$$

We also find from [34, Lemma 5.13] that for every $r > 0$, $K_{\nu}(r) \leq \sqrt{2\pi} r^{-\frac{1}{2}} e^{-r \nu^2}$. Consequently, by adjusting $M$ if need be so that $e^{-\frac{\nu^2}{2\pi}} \leq 2$ for $\xi \in \mathbb{R}^d \setminus [-M, M]^d$, we find that there is a positive constant $\beta$ such that $K_{\alpha+\frac{d}{2}}(c\|\xi\|) \leq \beta e^{-c\|\xi\|}$. We conclude that

$$
I \leq D^{-1} e^{4\pi c} \int_{\mathbb{R}^d \setminus [-M, M]^d} |\hat{\phi}_{\alpha,c}(\xi)| d\xi
\leq \beta D^{-1} |\lambda| e^{4\pi c} \int_{\mathbb{R}^d \setminus [-M, M]^d} \|\xi\|^{-\alpha - \frac{d}{2}} e^{-c\|\xi\|} d\xi.
$$

The integral on the right hand side above is convergent, and the constants outside are all finite, so $\hat{L}_{\alpha,c} \in L_1(\mathbb{R}^d)$. $\square$

Now we turn our attention to the function $L_{\alpha,c}$.

**Proposition 2** Let $\alpha \in \mathbb{R} \setminus \mathbb{N}_0$ and $c > 0$. Then the function

$$
L_{\alpha,c}(x) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} \hat{L}_{\alpha,c}(\xi) e^{i\langle x, \xi \rangle} d\xi
$$

is continuous, square-integrable, and satisfies the interpolatory condition $L_{\alpha,c}(k) = \delta_{0,k}$, for every $k \in \mathbb{Z}^d$.

**Proof** Proposition 1 implies that $L_{\alpha,c}$ is continuous and square-integrable, and indeed that $L_{\alpha,c}$ is its Fourier transform. To see the interpolatory condition,
first define $Q_d := [-\pi, \pi]^d$. Then we have via the substitution $u = \xi + 2\pi \ell$
that

$$L_{\alpha, c}(k) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} \sum_{j \in \mathbb{Z}^d} \hat{\phi}_{\alpha, c}(\xi + 2\pi j) e^{i(k, \xi)} d\xi$$

$$= \frac{1}{(2\pi)^d} \sum_{\ell \in \mathbb{Z}^d} \int_{Q_d} \sum_{j \in \mathbb{Z}^d} \hat{\phi}_{\alpha, c}(\xi + 2\pi j) e^{i(k, \xi)} d\xi$$

$$= \frac{1}{(2\pi)^d} \int_{Q_d} \sum_{\ell \in \mathbb{Z}^d} \sum_{j \in \mathbb{Z}^d} \hat{\phi}_{\alpha, c}(u - 2\pi \ell) e^{-i(k, 2\pi \ell)} e^{i(k, u)} du$$

$$= \frac{1}{(2\pi)^d} \int_{Q_d} e^{i(k, u)} du$$

$$= \delta_{0, k}.$$

The interchange of sum and integral in the third line is justified by the Dominated Convergence Theorem, for example.

It is an important observation that much of the cardinal interpolation theory for bandlimited functions revolves around the fact that the fundamental functions converge to the sinc function, which is equivalent to the statement that the Fourier transform of the fundamental function converges almost everywhere to the indicator function of the cube $[-\pi, \pi]^d$. The story is no different here. Defining $I$ to be the function that takes value 1 whenever $\xi \in [-\pi, \pi]^d$, and 0 elsewhere, the following holds.

**Proposition 3** Let $\alpha \in \mathbb{R} \setminus \mathbb{N}_0$. Then

$$\lim_{c \to \infty} \hat{L}_{\alpha, c}(\xi) = I(\xi)$$

for all $\xi \in \mathbb{R}^d$ such that $\max\{|\xi_1|, \ldots, |\xi_d|\} \neq \pi$.

**Proof** First suppose that $\xi \notin [-\pi, \pi]^d$. Then there exists some $k_0 \in \mathbb{Z}^d$ such that $\|\xi + 2\pi k_0\| < \|\xi\|$. Therefore by Lemma 1,

$$|\hat{\phi}_{\alpha, c}(\xi)| \leq \left( \frac{\|\xi\|}{\|\xi + 2\pi k_0\|} \right)^{-\alpha - \frac{d}{2}} e^{-c(\|\xi\| - \|\xi + 2\pi k_0\|)} |\hat{\phi}_{\alpha, c}(\xi + 2\pi k_0)|$$

$$\leq \left( \frac{\|\xi\|}{\|\xi + 2\pi k_0\|} \right)^{-\alpha - \frac{d}{2}} e^{-c(\|\xi\| - \|\xi + 2\pi k_0\|)} \sum_{k \in \mathbb{Z}^d} |\hat{\phi}_{\alpha, c}(\xi + 2\pi k)|.$$
Consequently, since $\hat{\phi}_{\alpha,c}$ is of one sign,

$$0 \leq L_{\alpha,c}(\xi) \leq \left( \frac{\|\xi\|}{\|\xi + 2\pi k_{0}\|} \right)^{-\alpha - \frac{d}{2}} e^{-c(\|\xi\| - \|\xi + 2\pi k_{0}\|)}.$$ 

Since the exponent is negative, the limit of the right hand side as $c \to \infty$ is 0. Therefore, for $\xi \notin [-\pi, \pi]^{d}$, $\lim_{c \to \infty} L_{\alpha,c}(\xi) = 0$.

Now suppose that $\xi \in (-\pi, \pi)^{d}$. Then for all $k \in \mathbb{Z} \setminus \{0\}$, $\|\xi\| < \|\xi + 2\pi k\|$. Due to Eq. 6, we may write

$$L_{\alpha,c}(\xi) = \left( 1 + \sum_{k \neq 0} \frac{\hat{\phi}_{\alpha,c}(\xi + 2\pi k)}{\hat{\phi}_{\alpha,c}(\xi)} \right)^{-1},$$

and therefore it suffices to show that

$$\lim_{c \to \infty} \sum_{k \neq 0} \frac{\hat{\phi}_{\alpha,c}(\xi + 2\pi k)}{\hat{\phi}_{\alpha,c}(\xi)} = 0.$$

By Lemma 1,

$$0 \leq \sum_{k \neq 0} \frac{\hat{\phi}_{\alpha,c}(\xi + 2\pi k)}{\hat{\phi}_{\alpha,c}(\xi)} \leq \sum_{k \neq 0} \left( \frac{\|\xi + 2\pi k\|}{\|\xi\|} \right)^{-\alpha - \frac{d}{2}} e^{-c(\|\xi + 2\pi k\| - \|\xi\|)}.$$ 

The series on the right hand side is convergent and dominated by the convergent series where $c$ is replaced by 1, so

$$\lim_{c \to \infty} \sum_{k \neq 0} \frac{\hat{\phi}_{\alpha,c}(\xi + 2\pi k)}{\hat{\phi}_{\alpha,c}(\xi)} = 0$$

as desired. Convergence of the series stems from the fact that if $\alpha + \frac{d}{2} > 0$, then the fraction term is less than 1, and so the series is majorized by $\sum_{k \neq 0} e^{-2\pi c \|k\|}$, which converges. On the other hand, if $\alpha + \frac{d}{2} < 0$, the sum is majorized by $\sum_{k \neq 0} (1 + \frac{k}{\|\xi\|})^{-\alpha - \frac{d}{2}} e^{-2\pi c \|k\|}$, which is again convergent.

We now consider interpolation of bandlimited functions at the lattice $\mathbb{Z}^{d}$ by translates of the function $L_{\alpha,c}$. Define the $d$-dimensional Paley-Wiener space by

$$PW_{\pi}^{(d)} := \{ f \in L_{2}(\mathbb{R}^{d}) : \hat{f} = 0 \text{ a.e. outside } [-\pi, \pi]^{d} \}.$$ 

We begin our analysis with an $L_{2}$ version of the Poisson Summation Formula:

**Lemma 2** (cf. [3] Lemma 3.2) If $f \in PW_{\pi}^{(d)}$, then

$$\sum_{j \in \mathbb{Z}^{d}} \hat{f}(\xi + 2\pi j) = \sum_{j \in \mathbb{Z}^{d}} f(j) e^{-i(j,\xi)},$$

(10)

where the second series is convergent in $L_{2}(\mathbb{R}^{d})$. 

© Springer
Lemma 3 Let $f \in \mathcal{P}W_{\pi}^{(d)}$. For $m \in \mathbb{N}$, define

$$\mathcal{J}_{\alpha, c}^m f(\xi) := \left( \sum_{\|k\|_1 \leq m} f(k) e^{-i(k, \xi)} \right) \mathcal{L}_{\alpha, c}(\xi), \quad \xi \in \mathbb{R}^d,$$

where $\|k\|_1 = \sum_{i=1}^d |k_i|$ for $k \in \mathbb{Z}^d$. Then $(\mathcal{J}_{\alpha, c}^m f)_{m \in \mathbb{N}}$ forms a Cauchy sequence in $L_2(\mathbb{R}^d)$.

Proof Define $Q_m : \mathbb{R}^d \to \mathbb{R}$ via

$$Q_m(\xi) = \sum_{\|k\|_1 \leq m} f(k) e^{-i(k, \xi)}.$$

Thus, $\mathcal{J}_{\alpha, c}^m f(\xi) = Q_m(\xi) \mathcal{L}_{\alpha, c}(\xi)$. From Lemma 2, it is clear that $(Q_m)_{m \in \mathbb{N}}$ is a Cauchy sequence in $L_2[-\pi, \pi]^d$. So

$$\|\mathcal{J}_{\alpha, c}^m f - \mathcal{J}_{\alpha, c}^\ell f\|^2_{L_2(\mathbb{R}^d)} \leq \int_{\mathbb{R}^d} |Q_m(\xi) - Q_\ell(\xi)|^2 \left( \mathcal{L}_{\alpha, c}(\xi) \right)^2 d\xi$$

$$= \sum_{k \in \mathbb{Z}^d} \int_{[-\pi, \pi]^d} |Q_m(\xi + 2\pi k) - Q_\ell(\xi + 2\pi k)|^2$$

$$\times \left( \mathcal{L}_{\alpha, c}(\xi + 2\pi k) \right)^2 d\xi$$

$$= \int_{[-\pi, \pi]^d} |Q_m(\xi) - Q_\ell(\xi)|^2 \sum_{k \in \mathbb{Z}^d} \left( \mathcal{L}_{\alpha, c}(\xi + 2\pi k) \right)^2 d\xi$$

$$\leq \int_{[-\pi, \pi]^d} |Q_m(\xi) - Q_\ell(\xi)|^2 d\xi.$$

The interchange of sum and integral is valid by Tonelli’s Theorem, and the last inequality follows from the fact that

$$\sum_{k \in \mathbb{Z}^d} \left( \mathcal{L}_{\alpha, c}(\xi + 2\pi k) \right)^2 = \sum_{k \in \mathbb{Z}^d} \phi_{\alpha, c}(\xi + 2\pi k)^2 = \left( \sum_{l \in \mathbb{Z}^d} \phi_{\alpha, c}(\xi + 2\pi l) \right)^2 \leq 1. \quad (11)$$

We also used the fact that for $k \in \mathbb{Z}^d$, $Q_m(\xi + 2\pi k) = Q_m(\xi)$. We conclude that $(\mathcal{J}_{\alpha, c}^m f)_{m \in \mathbb{N}}$ is a Cauchy sequence in $L_2(\mathbb{R}^d)$ because $\|\mathcal{J}_{\alpha, c}^m f - \mathcal{J}_{\alpha, c}^\ell f\|_{L_2(\mathbb{R}^d)} \leq \|Q_m - Q_\ell\|_{L_2[-\pi, \pi]^d}$, and the latter is Cauchy.

Lemmas 2 and 3 allow us to define

$$\mathcal{J}_{\alpha, c} f(\xi) := \mathcal{L}_{\alpha, c}(\xi) \sum_{k \in \mathbb{Z}^d} f(k) e^{-i(k, \xi)}, \quad (12)$$
where the series is convergent in $L_2(\mathbb{R}^d)$. By a periodization argument similar to that in the proof of Lemma 3, one can show that $\widehat{J}_{\alpha,c} \hat{f} \in L_1(\mathbb{R}^d)$. Thus applying the Fourier inversion formula we see that

$$I_{\alpha,cf}(x) = \sum_{k \in \mathbb{Z}^d} f(k) L_{\alpha,c}(x-k), \quad x \in \mathbb{R}^d.$$ 

**Theorem 1** Let $\alpha \in \mathbb{R} \setminus \mathbb{N}_0$. If $f \in PW_\pi^{(d)}$, then

$$\lim_{c \to \infty} \| I_{\alpha,cf} - f \|_{L_2(\mathbb{R}^d)} = 0,$$

and

$$\lim_{c \to \infty} | I_{\alpha,cf}(x) - f(x) | = 0 \text{ uniformly on } \mathbb{R}^d.$$

**Proof** We will first prove uniform convergence. The proof is the same as in [3]. Again let $I$ be the characteristic function of the cube. Then we see by the inversion formula and the oft-exploited periodization argument, that

$$I_{\alpha,cf}(x) - f(x) = \frac{1}{(2\pi)^d} \int_{\mathbb{R}^d} \sum_{k \in \mathbb{Z}^d} \hat{f}(\xi + 2\pi k) \left( \widehat{L_{\alpha,c}}(\xi) - I(\xi) \right) e^{-i\langle x, \xi \rangle} d\xi$$

$$= \frac{1}{(2\pi)^d} \int_{[-\pi,\pi]^d} \hat{f}(\xi) \sum_{k \in \mathbb{Z}^d} \left( \widehat{L_{\alpha,c}}(\xi + 2\pi k) - I(\xi + 2\pi k) \right) e^{-i\langle x, \xi + 2\pi k \rangle} d\xi.$$

Therefore, we find that

$$| I_{\alpha,cf}(x) - f(x) | \leq \frac{1}{(2\pi)^d} \int_{[-\pi,\pi]^d} | \hat{f}(\xi)| \sum_{k \in \mathbb{Z}^d} L_{\alpha,c}(\xi + 2\pi k) - I(\xi + 2\pi k) d\xi$$

$$= \frac{1}{(2\pi)^d} \int_{[-\pi,\pi]^d} | \hat{f}(\xi)| \left( 1 - \widehat{L_{\alpha,c}}(\xi) + \sum_{k \neq 0} \hat{L_{\alpha,c}}(\xi + 2\pi k) \right) d\xi.$$

But then by definition,

$$\sum_{k \neq 0} \hat{L_{\alpha,c}}(\xi + 2\pi k) = \sum_{k \in \mathbb{Z}^d} \hat{\phi_{\alpha,c}}(\xi + 2\pi k) - \hat{\phi_{\alpha,c}}(\xi) = 1 - \widehat{L_{\alpha,c}}(\xi).$$

Therefore,

$$| I_{\alpha,cf}(x) - f(x) | \leq 2 \frac{1}{(2\pi)^d} \int_{[-\pi,\pi]^d} | \hat{f}(\xi)|(1 - \widehat{L_{\alpha,c}}(\xi)) d\xi.$$

As the integrand is non-negative and bounded by $2|\hat{f}(\xi)| \in L_1[-\pi, \pi]^d$, and

$$\lim_{c \to \infty} (1 - \widehat{L_{\alpha,c}}(\xi)) = 0,$$

the Dominated Convergence Theorem implies that

$$\lim_{c \to \infty} | I_{\alpha,cf}(x) - f(x) | = 0, \quad x \in \mathbb{R}^d.$$

The upper bound is independent of $x$, hence the convergence is uniform.
We now turn to the proof of $L_2$ convergence. By Parseval’s Identity, it suffices to show that $\| \mathcal{J}_{\alpha,c} \hat{f} - \hat{f} \|_{L_2(\mathbb{R}^d)} \to 0$. This breaks up into two estimates. We first show this for the cube $[-\pi, \pi]^d$. Recall that since $(e^{-i(k,\cdot)})_{k \in \mathbb{Z}^d}$ is an orthonormal basis for $L_2[-\pi, \pi]^d$, we may write $\hat{f}(\xi) = \sum_{k \in \mathbb{Z}^d} f(k) e^{-i(k,\xi)}$. Moreover,

$$\| \hat{f} \|_{L_2[-\pi,\pi]^d} = \| f \|_{\ell_2(\mathbb{Z}^d)}.$$

Thus using Eq. 12,

$$\left\| \mathcal{J}_{\alpha,c} \hat{f} - \hat{f} \right\|^2_{L_2[-\pi,\pi]^d} = \int_{[-\pi,\pi]^d} \left| \sum_{k \in \mathbb{Z}^d} f(k) (\hat{L}_{\alpha,c}(\xi) - 1) e^{-i(k,\xi)} \right|^2 d\xi = \int_{[-\pi,\pi]^d} \left| \hat{L}_{\alpha,c}(\xi) - 1 \right|^2 \left| \sum_{k \in \mathbb{Z}^d} f(k) e^{-i(k,\xi)} \right|^2 d\xi.$$

The right hand side is bounded by $4 \| f(k) \|^2_{\ell_2(\mathbb{Z}^d)}$, and so by the Dominated Convergence Theorem and Proposition 3, $\lim_{c \to \infty} \| \mathcal{J}_{\alpha,c} \hat{f} - \hat{f} \|_{L_2[-\pi,\pi]^d} = 0$.

Now for the rest of the space, for $l = (l_1, l_2, \ldots, l_d) \in \mathbb{Z}^d \setminus \{0\}$, define $Q_l = [-\pi - 2\pi l_1, \pi - 2\pi l_1] \times \cdots \times [-\pi - 2\pi l_d, \pi - 2\pi l_d]$. Then we see that since $f$ is bandlimited,

$$\| \mathcal{J}_{\alpha,c} \hat{f} - \hat{f} \|^2_{L_2(\mathbb{R}^d \setminus [-\pi,\pi]^d)} = \sum_{l \neq 0} \| \mathcal{J}_{\alpha,c} \hat{f} \|^2_{L_2(Q_l)}.$$

Consequently,

$$\int_{\mathbb{R}^d \setminus [-\pi,\pi]^d} \left| \mathcal{J}_{\alpha,c} \hat{f}(\xi) \right|^2 d\xi = \sum_{l \neq 0} \int_{Q_l} \left| \hat{L}_{\alpha,c}(\xi) \sum_{k \in \mathbb{Z}^d} f(k) e^{-i(k,\xi)} \right|^2 d\xi = \int_{[-\pi,\pi]^d} \sum_{l \neq 0} \left| \hat{L}_{\alpha,c}(\xi + 2\pi l) \right|^2 \left| \sum_{k \in \mathbb{Z}^d} f(k) e^{-i(k,\xi)} \right|^2 d\xi,$$

by the Monotone Convergence Theorem.

Recall that $0 \leq \hat{L}_{\alpha,c}(\xi) \leq 1$, so $|\hat{L}_{\alpha,c}(\xi + 2\pi l)|^2 \leq \hat{L}_{\alpha,c}(\xi + 2\pi l)$, and as calculated above, $\sum_{\ell \neq 0} \hat{L}_{\alpha,c}(\xi + 2\pi \ell) = 1 - \hat{L}_{\alpha,c}(\xi)$. Consequently, the integrand is bounded by

$$\left| 1 - \hat{L}_{\alpha,c}(\xi) \right| \left| \sum_{k \in \mathbb{Z}^d} f(k) e^{-i(k,\xi)} \right|^2 \leq 2 \| f(k) \|^2_{\ell_2(\mathbb{Z}^d)}.$$

Therefore, the Dominated Convergence Theorem and Proposition 3 imply that $\lim_{c \to \infty} \| \mathcal{J}_{\alpha,c} \hat{f} \|_{L_2(\mathbb{R}^d \setminus [-\pi,\pi]^d)} = 0$, and the proof is complete. \qed
To illustrate the convergence given by Theorem 1 above, Fig. 3 shows the inverse multiquadric interpolant of the function whose Fourier transform is $\hat{g}(\xi) = \xi^2$ in dimension 1.

4 Properties of the fundamental function

For the rest of the paper, we turn our attention to the one-dimensional cardinal interpolation operator associated with the general multiquadric. This section is devoted to the one-dimensional fundamental function $L_{\alpha,c}$, whose Fourier transform can be rewritten as

$$L_{\alpha,c}(\xi) = \left[1 + \sum_{j \neq 0} \frac{\hat{\phi}_{\alpha,c}(\xi + 2\pi j)}{\hat{\phi}_{\alpha,c}(\xi)}\right]^{-1}. \quad (13)$$

The proofs of the results in this section are quite technical, so we postpone them until Section 7 and simply state our conclusions here.

To determine decay rates for $L_{\alpha,c}$, we determine how many derivatives $\hat{L}_{\alpha,c}$ has in $L_1$, which we accomplish by establishing pointwise estimates. We begin by fixing $\varepsilon \in [0, 1)$, so that our estimates fall into three ranges: $|\xi| \leq \pi(1 - \varepsilon)$, $\pi(1 + \varepsilon) < |\xi| \leq 3\pi$, and the $2\pi$-length blocks $[-2j - 1, -2j + 1]\pi$ for $|j| \geq 2$. Due to the differing behavior of $\hat{\phi}_{\alpha,c}$ for positive and negative values of $\alpha$, we must make corresponding distinctions in our calculations.

Following the insightful techniques of Riemenschneider and Sivakumar found in [29], we begin by defining some auxiliary functions to aid in the analysis of the fundamental function. We abbreviate (13) as $\hat{L}_{\alpha,c}(\xi) = (1 + s_{\alpha,c}(\xi))^{-1}$, where

$$s_{\alpha,c}(\xi) := \sum_{j \neq 0} \frac{\hat{\phi}_{\alpha,c}(\xi + 2\pi j)}{\hat{\phi}_{\alpha,c}(\xi)} =: \sum_{j \neq 0} a_j(\xi), \quad (14)$$

and study the properties of $a_j$. 

---

**Fig. 3** Plot of the function $g$ and its multiquadric interpolant for $\alpha = -1/2$ and both $c = 1$ (left) and $c = 10$ (right)
Proposition 4 Suppose that $\alpha \in (0, \infty) \setminus \mathbb{N}$, $\varepsilon \in [0, 1)$, $c \geq 1$, and $k \in \mathbb{N}_0$. If $|\xi| \leq \pi(1-\varepsilon)$ and $k \leq 2\alpha + 1$, then there exists a constant $A_{\alpha,k}(\varepsilon) > 0$ such that

$$|a_j^{(k)}(\xi)| \leq A_{\alpha,k}(\varepsilon)c^{(k+1)(2\alpha-|\alpha|)+k}e^{-2\pi c\varepsilon}e^{-2\pi c(|j|-1)},$$

where $A_{\alpha,k}(\varepsilon) = O(1)$ as $\varepsilon \to 0$.

This estimate leads to the following bounds on $\hat{L}_{\alpha,c}$ and its derivatives.

Proposition 5 Suppose that $\alpha \in (0, \infty) \setminus \mathbb{N}$, $\varepsilon \in [0, 1)$, $c \geq 1$, and $k \in \mathbb{N}_0$. If $k \leq 2\alpha + 1$, then there exist constants $A_{\alpha,k}(\varepsilon), A_{\alpha,k} > 0$ such that

(i) $|\hat{L}_{\alpha,c}^{(k)}(\xi)| \leq A_{\alpha,k}(\varepsilon)c^{2k(2\alpha-|\alpha|)+k}e^{-2\pi c\varepsilon}$ whenever $|\xi| \leq \pi(1-\varepsilon)$,

(ii) $|\hat{L}_{\alpha,c}^{(k)}(\xi)| \leq A_{\alpha,k}(\varepsilon)c^{(2k+1)(2\alpha-|\alpha|)+k}e^{-\pi c\varepsilon}$ whenever $|\xi| \in [(1+\varepsilon)\pi, 3\pi]$, and

(iii) $|\hat{L}_{\alpha,c}^{(k)}(\xi)| \leq A_{\alpha,k}c^{(2k+1)(2\alpha-|\alpha|)+k}e^{-2\pi c(|j|-1)}$ whenever $\xi \in [(-2j-1)\pi, (-2j+1)\pi]$ and $|j| \geq 2$,

where $A_{\alpha,k}(\varepsilon) = O(1)$ as $\varepsilon \to 0$.

These pointwise estimates yield the following result.

Theorem 2 Suppose that $\alpha \in (0, \infty) \setminus \mathbb{N}$, $c \geq 1$, and $k \in \mathbb{N}_0$. If $k \leq 2\alpha + 1$, then there exists a constant $A_{\alpha,k} > 0$ such that

$$\|\hat{L}_{\alpha,c}^{(k)}\|_{L^1(\mathbb{R})} \leq A_{\alpha,k}c^{(2k+1)(2\alpha-|\alpha|)+k}.$$  (16)

Using standard arguments, we have the following estimate for the growth rate of $L_{\alpha,c}$.

Corollary 1 If $\alpha \in (0, \infty) \setminus \mathbb{N}$ and $c \geq 1$, then $L_{\alpha,c}(x) = O(|x|^{-[2\alpha+1]})$ as $|x| \to \infty$.

Analogous estimates can be made for the case that $\alpha < -1$. Of interest to us are the following results.

Theorem 3 Suppose that $\alpha < -1$, $c \geq 1$, and $k \in \mathbb{N}_0$. If $k < 2|\alpha| - 1$, then there exists a constant $A_{\alpha,k} > 0$ such that

$$\|\hat{L}_{\alpha,c}^{(k)}\|_{L^1(\mathbb{R})} \leq A_{\alpha,k}c^{(2k+1)(2\alpha-|\alpha|-1)+k}.$$  (17)

Corollary 2 If $\alpha < -1$ and $c \geq 1$, then $L_{\alpha,c}(x) = O(|x|^{-[2|\alpha|-2]})$ as $|x| \to \infty$.

It turns out that the Poisson kernel, which is the case $\alpha = -1$, is a special case, and exhibits much better decay because $\hat{\phi}_{-1,c}$ is purely an exponential function.
Theorem 4 Suppose that $c \geq 1$. Then for every $k \in \mathbb{N}_0$, there exists a constant $A_k > 0$ such that
\[
\|\hat{L}_{-1,c}^{(k)}\|_{L_1(\mathbb{R})} \leq A_k c^k.
\] (18)

Corollary 3 Suppose that $c \geq 1$. Then $L_{-1,c}(x) = O(|x|^{-k})$ as $|x| \to \infty$ for every $k \in \mathbb{N}_0$.

We may refine the above estimates in the case $k = 1$ to find a uniform bound on the $L_1$-norm of $\hat{L}_{\alpha,c}'$.

Theorem 5 Suppose that $\alpha \in ((-\infty, -1] \cup (0, \infty)) \setminus \mathbb{N}$. There exists a constant $A_\alpha > 0$ such that for all $c \geq 1$, $\|\hat{L}_{\alpha,c}'\|_{L_1(\mathbb{R})} \leq A_\alpha$.

So far, the upper bounds on $L_{\alpha,c}$ may depend on the parameters $\alpha$ and $c$; however, the following still holds.

Lemma 4 If $\alpha \in ((-\infty, -1] \cup (0, \infty)) \setminus \mathbb{N}$ and $c \geq 1$, then $|L_{\alpha,c}(x)| \leq 1$ for all $x \in \mathbb{R}$.

We end the section with a statement on the zeros of $\hat{L}_{\alpha,c}$.

Theorem 6 If $\alpha \in ((-\infty, -1] \cup (0, \infty)) \setminus \mathbb{N}$ and $c \geq 1$, then $\hat{L}_{\alpha,c}(2\pi k) = \delta_{0,k}$ for every $k \in \mathbb{Z}$.

5 Norms and convergence properties of the one-dimensional interpolation operator

In this section, we show that the results of Riemenschneider and Sivakumar [29] have analogues for general multiquadrics. In Section 4, the decay of $\hat{L}_{\alpha,c}$ is discussed, and we use that information to uncover growth conditions on data that are suitable to cardinal interpolation. Recall from Corollary 1 and Theorem 6 that for $\alpha > 0$ and $c \geq 1$,
\[
|L_{\alpha,c}(x)| = O \left( \min \left\{ 1, |x|^{-2\alpha+1} \right\} \right), \quad x \in \mathbb{R}.
\] (19)

This decay is not the best one can get for individual $\alpha$, in fact for $\alpha = 1/2$, Buhmann [7] proves a decay rate of $|x|^{-5}$. According to further work by Buhmann and Micchelli [10], it appears that the multiquadrics with exponents $(2k - 1)/2$ for $k \in \mathbb{N}$ are exceptional cases. For these values, $L_{\alpha,c}$ can be shown to have more derivatives than what we have shown for general $\alpha$ due to some special symmetry involving the Bessel functions in the Fourier transforms. Moreover, in these cases, decay of the fundamental function is given by
\[
\left| L_{2k-1/2,c}(x) \right| = O \left( \min \left\{ 1, |x|^{-4k-1} \right\} \right), \quad x \in \mathbb{R}.
\] (20)
For negative exponents, the so-called inverse multiquadrics, the fundamental functions have slightly slower decay (Corollary 2 and Theorem 6):

\[ |L_{\alpha,c}(x)| = O \left( \min \left\{ 1, |x|^{-\left\lfloor |2\alpha|-2 \right\rfloor} \right\} \right), \quad x \in \mathbb{R}. \]  

(21)

As a consequence of the decay of the fundamental functions, we have the following.

**Proposition 6** For \( \alpha \in (-\infty, -3/2) \cup [1/2, \infty) \setminus \mathbb{N} \), the function

\[ \Lambda_{\alpha,c}(x) := \sum_{j \in \mathbb{Z}} |L_{\alpha,c}(x + j)|, \quad x \in \mathbb{R} \]  

is a well-defined, 1-periodic, bounded, continuous function.

**Proof** Periodicity is apparent, so we need only consider \( x \in [0, 1] \). If \( \alpha \geq 1/2 \), then Eq. 19 gives

\[ \Lambda_{\alpha,c}(x) = \sum_{j=-1}^{1} |L_{\alpha,c}(x+j)| + \sum_{|j|\geq2} |L_{\alpha,c}(x-j)| = O \left( 1 + \sum_{|j|\geq2} (|j| - 1)^{-|2\alpha+1|} \right), \]

which yields the result since \( L_{\alpha,c} \) is continuous on \( \mathbb{R} \) and \( 2\alpha + 1 \geq 2 \).

On the other hand, if \( \alpha < -3/2 \), then

\[ \Lambda_{\alpha,c}(x) = O \left( 1 + \sum_{|j|\geq2} (|j| - 1)^{-|2\alpha+1|} \right). \]

As the exponent is less than -1, the series converges, whence the result. \( \square \)

We next define the cardinal interpolation operator acting on sequences, and show that it is well-defined for sequences that grow at a sufficiently slower rate than the decay of the fundamental function.

**Theorem 7** If \( \alpha \in [1/2, \infty) \setminus \mathbb{N} \), and

\[ |y_j| \leq A \left( 1 + |j|^{\left\lfloor 2\alpha+1 \right\rfloor - 1-\varepsilon} \right), \quad j \in \mathbb{Z}, \]

for some fixed positive constants \( \varepsilon \) and \( A \), then the function

\[ \mathcal{I}_{\alpha,c}(x) := \sum_{j \in \mathbb{Z}} y_j L_{\alpha,c}(x - j), \quad x = (y_j)_{j \in \mathbb{Z}} \]  

(23)

is well-defined, continuous on \( \mathbb{R} \), and satisfies \( \mathcal{I}_{\alpha,c}(x) = O \left( 1 + |x|^{\left\lfloor 2\alpha+1 \right\rfloor - 1-\varepsilon} \right), \quad |x| \to \infty. \)

If \( \alpha \in (-\infty, -3/2) \), and

\[ |y_j| \leq A \left( 1 + |j|^{\left\lfloor 2\alpha-2 \right\rfloor - 1-\varepsilon} \right), \quad j \in \mathbb{Z}, \]

then \( \mathcal{I}_{\alpha,c} \) as defined in Eq. 23 is well-defined, continuous on \( \mathbb{R} \), and satisfies \( \mathcal{I}_{\alpha,c}(x) = O \left( 1 + |x|^{\left\lfloor 2\alpha-2 \right\rfloor - 1-\varepsilon} \right). \)
Proof Consider the case $\alpha \in [1/2, \infty) \setminus \mathbb{N}$. We first show that $\mathcal{I}_{\alpha,c} y$ is continuous on every interval of the form $[-M, M]$, for $M \in \mathbb{N}$. Let $x \in [-M, M]$. Then

$$\mathcal{I}_{\alpha,c} y(x) = \sum_{|j| \leq 2M} y_j L_{\alpha,c}(x - j) + \sum_{|j| > 2M} y_j L_{\alpha,c}(x - j).$$

The first term on the right hand side is a finite sum of continuous functions, and so it suffices to show that the second sum converges uniformly on $[-M, M]$. Indeed, the decay rates of $|y_j|$ and $L_{\alpha,c}$ yield the estimate

$$\sum_{|j| > 2M} |y_j L_{\alpha,c}(x - j)| \leq A \sum_{|j| > 2M} \frac{1 + |j|^{2\alpha+1-1-\varepsilon}}{|j|^{2\alpha+1}},$$

which converges because $\varepsilon > 0$ and $2\alpha + 1 \geq 2$.

Now to consider the decay of $\mathcal{I}_{\alpha,c}$, let $|x| \geq 1$ be fixed. Then let $v := v(x)$ be the unique integer such that $v(x) - 1/2 \leq x < v(x) + 1/2$. Since $v \neq 0$, $|v| < 2|x|$, and $|k - v| \leq 2|x - k|$ for every $k \neq v$, we have

$$|\mathcal{I}_{\alpha,c} y(x)| = |y_v L_{\alpha,c}(x - v) + \sum_{j \neq v} y_j L_{\alpha,c}(x - j)|$$

$$= O \left( 1 + |v|^{2\alpha+1-1-\varepsilon} + \sum_{j \neq v} \frac{1 + |j|^{2\alpha+1-1-\varepsilon}}{|j - v|^{2\alpha+1}} \right)$$

$$= O \left( 1 + |v|^{2\alpha+1-1-\varepsilon} \left( 1 + \sum_{j \neq 0} |j|^{2\alpha+1} \right) \right)$$

$$= O \left( 1 + |x|^{2\alpha+1-1-\varepsilon} \right).$$

The proof for negative $\alpha$ values follows similar reasoning.

Now we explore the properties of the cardinal interpolation operator $\mathcal{I}_{\alpha,c}$ acting on traditional sequence spaces; we first show boundedness, and follow with estimates on its norm.

**Theorem 8** For a fixed $\alpha \in (-\infty, -3/2) \cup [1/2, \infty) \setminus \mathbb{N}$ and $c > 0$, the cardinal interpolation operator $\mathcal{I}_{\alpha,c}$ is a bounded linear operator from $\ell_p$ to $L_p$ for $1 \leq p \leq \infty$.

**Proof** The proof is the same as in [29], which follows the techniques of [26]. Linearity is evident, and the cases $p = \infty$ and $p = 1$ follow from Proposition 6 and Lemma 4, respectively. Therefore, let $1 < p < \infty$, and $x \in \mathbb{R}$ be fixed. As before, let $v(x)$ be the unique integer such that $v(x) - 1/2 \leq x < v(x) + 1/2$. If $y = (y_j)_{j \in \mathbb{Z}} \in \ell_p$, then Theorem 7 implies that $\mathcal{I}_{\alpha,c} y$ is continuous, and we
Cardinal interpolation with general multiquadrics

$$\mathcal{I}_{\alpha,c} y(x) = y_{\nu(x)} L_{\alpha,c}(x - \nu(x)) + \sum_{j \neq \nu} y_j L_{\alpha,c}(x - j).$$

To estimate the $L_p$ norm of the first term, notice that since $|L_{\alpha,c}(x)| \leq 1$,

$$\int_{\mathbb{R}} \left| y_{\nu(x)} L_{\alpha,c}(x - \nu(x)) \right|^p \, dx = \sum_{\ell \in \mathbb{Z}} \int_{\ell - \frac{1}{2}}^{\ell + \frac{1}{2}} \left| y_{\nu(x)} L_{\alpha,c}(x - \nu(x)) \right|^p \, dx \leq \sum_{\ell \in \mathbb{Z}} |y_{\ell}|^p = \| y \|_{\ell_p}^p.$$

For the second term, first assume that $\alpha \in \left(1/2, \infty \right) \setminus \mathbb{N}$. Then

$$\int_{\mathbb{R}} \left| \sum_{j \neq \nu} y_j L_{\alpha,c}(x - j) \right|^p \, dx = \sum_{\nu \in \mathbb{Z}} \int_{\nu - \frac{1}{2}}^{\nu + \frac{1}{2}} \left| \sum_{j \neq \nu} y_j L_{\alpha,c}(x - j) \right|^p \, dx \leq \sum_{\nu \in \mathbb{Z}} \int_{\nu - \frac{1}{2}}^{\nu + \frac{1}{2}} \left( \sum_{j \neq \nu} |y_j||L_{\alpha,c}(x - j)| \right)^p \, dx = O \left( \sum_{\nu \in \mathbb{Z}} \left( \sum_{j \neq \nu} \frac{|y_j|}{|\nu - j|^{2\alpha + 1}} \right)^p \right).$$

The quantity in the final line above corresponds to the $\ell_p$ norm of the discrete convolution $|y| * b$, where $|y| = \left( |y_j| \right)_{j \in \mathbb{Z}}$, and the entries of $b$ are given by $(1 - \delta_{0,j})/|j|^{2\alpha + 1}$. From [6, p. 259, Theorem 7.6], we find that

$$\| |y| * b \|_{\ell_p} \leq \| y \|_{\ell_p} \left[ \sup_{n \in \mathbb{N}} n b^z(n) \right].$$

(24)

where $(b^z(n))_{n \in \mathbb{N}}$ is a non-increasing rearrangement of $b$. It is easily checked that the supremum on the right hand side of Eq. 24 is finite, and therefore the second term estimated above is $O(\| y \|_{\ell_p}^p)$, and the theorem follows.

The proof for the case $\alpha < -3/2$ is much the same, except that the power on the elements of $b$ will be $-\left(2|\alpha| - 2\right)$, which nevertheless results in the supremum of $n b^z(n)$ being finite.

**Theorem 9** Let $\alpha \in (-\infty, -3/2) \cup \left[1/2, \infty \right) \setminus \mathbb{N}$ and $1 < p < \infty$ be fixed. Then

$$\sup_{c \geq 1} \| \mathcal{I}_{\alpha,c} \|_{\ell_p \to L_p} < \infty.$$
Proof Consider a fixed $1 < p < \infty$, and $p'$ such that $\frac{1}{p} + \frac{1}{p'} = 1$. Let $y \in \ell_p$, $g \in L_{p'}$, and $v(x)$ be the unique integer such that $v(x) - 1/2 \leq x < v(x) + 1/2$. Then

$$\left| \int_{\mathbb{R}} \mathcal{I}_{\alpha,c} y(x)g(x)dx \right| = \left| \int_{\mathbb{R}} \sum_{j \in \mathbb{Z}} y_j L_{\alpha,c}(x - j)g(x)dx \right|$$

$$\leq \left| \int_{\mathbb{R}} y_{v(x)} L_{\alpha,c}(x - v(x))g(x)dx \right|$$

$$+ \left| \int_{\mathbb{R}} \sum_{j \neq v} y_j L_{\alpha,c}(x - j)g(x)dx \right|$$

$$=: I_1 + I_2.$$ 

By Hölder’s Inequality and the fact that $|L_{\alpha,c}(x)| \leq 1$,

$$I_1 \leq \|y\|_{\ell_p} \|g\|_{L_{p'}}.$$ 

To estimate $I_2$, we represent $L_{\alpha,c}$ by its Fourier integral (see Proposition 2) and integrate by parts. Indeed,

$$I_2 = \frac{1}{2\pi} \left| \int_{\mathbb{R}} \sum_{j \neq v} y_j \int_{\mathbb{R}} \hat{L}_{\alpha,c}(\xi)e^{i(x-j)\xi} d\xi g(x)dx \right|$$

$$= \frac{1}{2\pi} \left| \int_{\mathbb{R}} \sum_{j \neq v} \int_{\mathbb{R}} \frac{y_j}{x - j} e^{i(x-j)\xi} \hat{L}_{\alpha,c}'(\xi)g(x)d\xi dx \right|$$

$$= \frac{1}{2\pi} \left| \int_{\mathbb{R}} \hat{L}_{\alpha,c}'(\xi) \int_{\mathbb{R}} \sum_{j \neq v} \frac{y_j}{x - j} e^{-ij\xi} g(x)e^{ix\xi} dx d\xi \right|,$$

where the final step follows from Fubini’s Theorem.

From [26, Proposition 1.3], the mixed Hilbert transform defined by

$$\mathcal{H} y(x) := \sum_{j \neq v(x)} \frac{y_j}{x - j}$$

(25)
is a bounded linear operator from $\ell^p$ to $L^p$, and $\|\mathcal{H}\|_{\ell^p \to L^p} \leq A_p$, where $A_p$ is a constant depending only on $p$. Consequently,

$$I_2 = \frac{1}{2\pi} \left| \int_{\mathbb{R}} \widehat{L_{\alpha,c}}(\xi) \int_{\mathbb{R}} \mathcal{H} \left( ye^{-i(\cdot)\xi} \right) (x) g(x) e^{ix\xi} dx d\xi \right| \leq \frac{1}{2\pi} \|\widehat{L_{\alpha,c}}\|_{L^1} \|\mathcal{H}\|_{\ell^p \to L^p} \|y\|_{\ell^p} \|g\|_{L^p'} \leq A_{\alpha,p} \|y\|_{\ell^p} \|g\|_{L^p'}.$$

The final inequality comes from boundedness of the mixed Hilbert transform and Theorem 5. The conclusion of the theorem follows from the estimates on $I_1$ and $I_2$. We now estimate the norms in the cases $p = 1$ and $p = \infty$.

**Proposition 7** Suppose $\alpha \in (-\infty, -3/2) \cup [1/2, \infty) \setminus \mathbb{N}$ and $c \geq 1$ are fixed. The following hold:

(i) Let $\Lambda_{\alpha,c}$ be defined via (22). Then

$$\Lambda_{\alpha,c}(x) \leq A_\alpha \ln(c), \quad x \in \mathbb{R},$$

where $A_\alpha > 0$ is a constant.

(ii) $\|\mathcal{J}_{\alpha,c}\|_{\ell^\infty \to L^\infty} \leq A_\alpha \ln(c)$.

(iii) $\|\mathcal{J}_{\alpha,c}\|_{\ell^1 \to L^1} \leq A_\alpha \ln(c)$.

**Proof** We supply the proof for the case $\alpha \in [1/2, \infty)$, the estimates for the negative range of $\alpha$ being wholly similar.

(i) By Theorems 2 and 5,

$$|L_{\alpha,c}(x)| \leq A_\alpha \min \left\{1, \frac{1}{|x|}, \frac{c^{5\alpha+2}}{|x|^2} \right\}, \quad x \in \mathbb{R}, \quad c \geq 1. \quad (26)$$

Since $\Lambda_{\alpha,c}$ is 1-periodic, it suffices to check the inequality for $x \in [0, 1]$. Let $c \geq 1$ and $N := \lceil c^{5\alpha+2} \rceil$. Then by Eq. 26

$$ |\Lambda_{\alpha,c}(x)| \leq \sum_{j \in \mathbb{Z}} |L_{\alpha,c}(x + j)| \leq A_\alpha \left[ 1 + \sum_{2 \leq |j| \leq N} |x + j|^{-1} + \sum_{|j| > N} c^{5\alpha+2} |x + j|^{-2} \right] \leq A_\alpha \left[ 1 + \ln(N) + c^{5\alpha+2} N^{-1} \right],$$
whence the result.

(ii) Simply note that if \( y \in \ell_\infty \), then \( |\mathcal{I}_{\alpha,c} y(x)| \leq \|y\|_{\ell_\infty} \Lambda_{\alpha,c}(x) \), \( x \in \mathbb{R} \), and apply (i).

(iii) Similarly, if \( y \in \ell_1 \), then
\[
\int_{\mathbb{R}} \left| \sum_{j \in \mathbb{Z}} y_j L_{\alpha,c}(x-j) \right| dx \leq \|y\|_{\ell_1} \int_{0}^{1} \Lambda_{\alpha,c}(x) dx,
\]
whereby (i) provides the desired bound.

We make note that \( p = 2 \) provides an interesting special case.

\begin{theorem}
For any \( \alpha \in (-\infty, -3/2) \cup [1/2, \infty) \setminus \mathbb{N} \) and \( c \geq 1 \),
\[
\|\mathcal{I}_{\alpha,c}\|_{\ell_2 \to L_2} = 1.
\]
\end{theorem}

\begin{proof}
First, note that by Plancherel’s Identity and a standard periodization argument,
\[
\|\mathcal{I}_{\alpha,c} y\|_{L_2}^2 = \frac{1}{2\pi} \|\hat{\mathcal{I}_{\alpha,c}} y\|_{L_2}^2 = \frac{1}{2\pi} \int_{\mathbb{R}} \left( \sum_{j \in \mathbb{Z}} y_j e^{-ij\xi} \right)^2 \hat{\Lambda}_{\alpha,c}(\xi)^2 d\xi
= \frac{1}{2\pi} \int_{-\pi}^{\pi} \left( \sum_{j \in \mathbb{Z}} y_j e^{-ij\xi} \right)^2 \left( \sum_{k \in \mathbb{Z}} \hat{\Lambda}_{\alpha,c}(\xi + 2\pi k) \right)^2 d\xi. \tag{27}
\]
Consequently,
\[
\|\mathcal{I}_{\alpha,c} y\|_{L_2}^2 \leq \max_{\xi \in [-\pi,\pi]} \left( \sum_{k \in \mathbb{Z}} \hat{\Lambda}_{\alpha,c}(\xi + 2\pi k) \right)^2.
\]
Taking the supremum over \( y \) in the unit ball of \( \ell_2 \) yields
\[
\|\mathcal{I}_{\alpha,c}\|_{\ell_2 \to L_2} = \max_{\xi \in [-\pi,\pi]} \left( \sum_{k \in \mathbb{Z}} \hat{\Lambda}_{\alpha,c}(\xi + 2\pi k) \right)^2.
\]
That the maximum on the right hand side is at most 1 is the content of Eq. 11, but the maximum is attained at \( \xi = 0 \) by Theorem 6.
\end{proof}

Having established some information about the interpolation operators and their norms for different values of \( p \), we now shift our gaze to some convergence properties when the shape parameter \( c \to \infty \) for a fixed \( \alpha \). As one might expect, for large (in absolute value) \( \alpha \), we obtain better convergence results owing to the more rapid decay of the fundamental functions.

To begin our discussion, consider the \textit{Whittaker operator} defined via
\[
\mathcal{W}y(x) := \sum_{j \in \mathbb{Z}} y_j \frac{\sin(\pi(x-j))}{\pi(x-j)}, \quad x \in \mathbb{R}, \quad y = (y_j)_{j \in \mathbb{Z}}. \tag{28}
\]
This operator is bounded from $\ell_p$ to $L_p$ for $1 < p < \infty$, and the following holds.

**Theorem 11** If $y \in \ell_p$, $1 < p < \infty$, then for a fixed $\alpha \in (-\infty, -3/2) \cup [1/2, \infty) \setminus \mathbb{N}$,

$$\lim_{c \to \infty} \|I_{\alpha,c}y - \mathcal{W}y\|_{L_p} = 0.$$ 

**Proof** Boundedness of $\mathcal{W}$, Theorem 9, and the Uniform Boundedness Principle imply that it is sufficient to check convergence on the coordinate basis for $\ell_p$, $e_j := \delta_{0,j}$. That is, it suffices that

$$\|I_{\alpha,c}e_j - \mathcal{W}e_j\|_{L_p} = \left\|L_{\alpha,c}(\cdot - j) - \frac{\sin(\pi(\cdot - j))}{\pi(\cdot - j)}\right\|_{L_p} \to 0,$$

as $c \to \infty$. By Theorem 1, $|L_{\alpha,c}(x) - \sin(\pi x)/(\pi x)|$ converges to 0 uniformly as $c \to \infty$; moreover, Proposition 5 implies that $|I_{\alpha,c}(x)| \leq A/|x|$, whence an application of the Dominated Convergence Theorem yields the statement of the theorem.

Suppose a function $f$ has sufficiently slow growth so that $I_{\alpha,c}y$, with $y := (f(j))_{j \in \mathbb{Z}}$, is well-defined (see Theorem 7). In this case we let $I_{\alpha,c}f(x) := I_{\alpha,c}y(x)$, and call this the cardinal interpolant of $f$ due to the identity

$$I_{\alpha,c}f(j) = f(j), \quad j \in \mathbb{Z}.$$

We will consider pointwise and uniform convergence of $I_{\alpha,c}f$ to $f$ as $c \to \infty$, but first we must make some preliminary arrangements. Consider $\alpha$ to be fixed. Then define

$$\Phi_{\alpha,c}(x, t) := \sum_{j \in \mathbb{Z}} \widehat{L_{\alpha,c}}(t + 2\pi j) e^{-ix(t+2\pi j)}, \quad t, x \in \mathbb{R},$$

and

$$\Phi^{(k)}_{\alpha,c}(x, t) := \frac{\partial^k}{\partial t^k} \Phi_{\alpha,c}(x, t), \quad t, x \in \mathbb{R}. \quad (29)$$

**Lemma 5** If $\alpha \in [1/2, \infty) \setminus \mathbb{N}$ and $k \in \{0, 1, \ldots, |2\alpha + 1| - 2\}$, then $\Phi^{(k)}_{\alpha,c}$ is well-defined, continuous in each of its variables, and $2\pi$-periodic in the second variable.

If $\alpha \in (-\infty, -3/2)$ and $k \in \{0, 1, \ldots, |2\alpha| - 2\}$, then $\Phi^{(k)}_{\alpha,c}$ is well-defined, continuous in each of its variables, and $2\pi$-periodic in the second variable.

**Proof** Continuity of $\Phi^{(k)}_{\alpha,c}$ is provided by Corollaries 1 and 2, while Proposition 5 shows that the series $\sum_{j \in \mathbb{Z}} |\widehat{L_{\alpha,c}}(k)(t + 2\pi j)|$ is uniformly convergent on $[-\pi, \pi]$. Thus $\Phi_{\alpha,c}$ is well-defined and uniformly continuous for $t \in [-\pi, \pi]$, and moreover, we may differentiate the series term by term. Finally, $2\pi$-periodicity is evident.

Now let $C(\mathbb{T})$ be the space of continuous, $2\pi$-periodic functions on the real line, and let $M(\mathbb{T})$ denote its dual, which is the space of all $2\pi$-periodic complex...
Borel measures on the real line, with the total variation norm given by \( \|\mu\| := |\mu|((−\pi, \pi)) \). Following [22, p.37], given \( \mu \in M(\mathbb{T}) \), define the \( j \)-th Fourier-Stieltjes coefficient of \( \mu \) by

\[
\hat{\mu}(j) := \int_{-\pi}^{\pi} e^{-ijt} d\mu(t), \quad j \in \mathbb{Z},
\]

and the \( n \)-th Fejér mean of the Fourier-Stieltjes series of \( \mu \) by

\[
\sigma_n(\mu, t) := \sum_{j=-n}^{n} \left(1 - \frac{|j|}{n+1}\right) \hat{\mu}(j)e^{ijt}, \quad t \in \mathbb{R}, \quad n \in \mathbb{N}_0.
\]

We begin by showing that for certain functions, the interpolant exhibits a special form.

**Theorem 12** Let \( \alpha \) be fixed, and suppose \( f \) is given by

\[
f(x) := (ix)^k \int_{-\pi}^{\pi} e^{-ixt} d\mu(t), \quad x \in \mathbb{R},
\]

for some \( \mu \in M(\mathbb{T}) \) and some \( k = 0, 1, \ldots, [2\alpha+1] - 2 \) in the case \( \alpha \in [1/2, \infty) \setminus \mathbb{N} \) or \( k = 0, 1, \ldots, [2\alpha] - 2 \) in the case \( \alpha \in (-\infty, -3/2) \). Let \( \Phi^{(k)}_{\alpha,c} \) be defined by Eq. 30. Then

\[
\mathcal{I}_{\alpha,c} f(x) = \int_{-\pi}^{\pi} \Phi^{(k)}_{\alpha,c}(x, t)d\mu(t), \quad c > 0, \quad x \in \mathbb{R}.
\]

**Proof** By definition, \( |f(x)| \leq |x|^k \|\mu\| \), thus Theorem 7 implies that \( \mathcal{I}_{\alpha,c} f \) is well-defined and continuous. By property of the Fejér means,

\[
\mathcal{I}_{\alpha,c} f(x) = \lim_{n \to \infty} \sum_{j=-n}^{n} f(j)L_{\alpha,c}(x-j) = \lim_{n \to \infty} \sum_{j=-n}^{n} \left(1 - \frac{|j|}{n+1}\right) f(j)L_{\alpha,c}(x-j).
\]

Therefore, by the inversion formula and a standard periodization argument,

\[
\sum_{j=-n}^{n} f(j)L_{\alpha,c}(x-j) = \frac{1}{2\pi} \int_{\mathbb{R}} \left[ \sum_{j=-n}^{n} \left(1 - \frac{|j|}{n+1}\right) f(j)e^{ijt} \right] \Phi_{\alpha,c}(t)e^{-ixt} dt
\]

\[
= \frac{1}{2\pi} \int_{-\pi}^{\pi} \left[ \sum_{j=-n}^{n} \left(1 - \frac{|j|}{n+1}\right) f(j)e^{ijt} \right] \Phi_{\alpha,c}(x, t) dt.
\]
By definition, \( f(j) = (-ij)^k \hat{\mu}(j) \) for every \( j \in \mathbb{Z} \). So if \( k = 0 \), \( f(j) = \hat{\mu}(j) \), and if \( k > 0 \), \( f(0) = 0 \). Consequently, if \( k = 0 \), then

\[
\frac{1}{2\pi} \int_{-\pi}^{\pi} \left[ \sum_{j=-n}^{n} \left( 1 - \frac{|j|}{n + 1} \right) f(j) e^{ijt} \right] \Phi_{\alpha,c}(x, t) dt = \frac{1}{2\pi} \int_{-\pi}^{\pi} \sigma_n(\mu, t) \Phi_{\alpha,c}(x, t) dt.
\]

If \( k > 0 \), then we integrate (36) by parts \( k \) times. The boundary terms cancel due to periodicity, so

\[
\frac{1}{2\pi} \int_{-\pi}^{\pi} \left[ \sum_{j=-n}^{n} \left( 1 - \frac{|j|}{n + 1} \right) f(j) e^{ijt} \right] \Phi_{\alpha,c}(x, t) dt
\]

\[
= (-1)^k \frac{1}{2\pi} \int_{-\pi}^{\pi} \left[ \sum_{1 \leq |j| \leq n} \left( 1 - \frac{|j|}{n + 1} \right) \hat{\mu}(j) e^{ijt} \right] \Phi_{\alpha,c}(x, t) dt
\]

\[
= \frac{1}{2\pi} \int_{-\pi}^{\pi} \left[ \sum_{j=-n}^{n} \left( 1 - \frac{|j|}{n + 1} \right) \hat{\mu}(j) e^{ijt} \right] \Phi_{\alpha,c}(x, t) dt,
\]

(37)

where the final equality comes from the fact that \( \int_{-\pi}^{\pi} \Phi_{\alpha,c}^{(k)}(x, t) dt = 0 \) for \( k \geq 1 \).

Combining Eqs. 35, 36, and 37, we see that

\[
\mathcal{J}_{\alpha,c} f(x) = \lim_{n \to \infty} \frac{1}{2\pi} \int_{-\pi}^{\pi} \sigma_n(\mu, t) \Phi_{\alpha,c}^{(k)}(x, t) dt = \int_{-\pi}^{\pi} \Phi_{\alpha,c}^{(k)}(x, t) d\mu(t).
\]

Using Theorem 12, we show the following result on uniform convergence.

**Theorem 13** Suppose \( \alpha \) is as above, and \( f \) is given by

\[
f(x) := (ix)^k \int_{-\pi}^{\pi} e^{-ixt} d\mu(t), \quad x \in \mathbb{R},
\]

for some \( k \) as in Theorem 12 and \( \mu \in M(\mathbb{T}) \) such that

\[
supp(\mu) \cap [-\pi, \pi) \subset [-\pi(1 - \varepsilon), \pi(1 - \varepsilon)],
\]

for some fixed \( 0 < \varepsilon < 1 \). Then

\[
\lim_{c \to \infty} \mathcal{J}_{\alpha,c} f(x) = f(x), \quad x \in \mathbb{R},
\]

with convergence being uniform on compact subsets of \( \mathbb{R} \). In the case \( k = 0 \), convergence is uniform on \( \mathbb{R} \).
Proof Suppose first that $k \geq 1$. Let $M > 0$ be fixed. We will show that $\mathcal{I}_{\alpha,c} f(x) \to f(x)$ uniformly for $|x| \leq M$. By Theorem 12 and the definitions of $f$ and $\Phi^{(k)}_{\alpha,c}$,

$$\mathcal{I}_{\alpha,c} f(x) - f(x) = \int_{-\pi(1-\varepsilon)}^{\pi(1-\varepsilon)} \frac{\partial^{k}}{\partial t^{k}} \left( \Phi_{\alpha,c}(x, t) - e^{-ixt} \right) d\mu(t)$$

$$= \int_{-\pi(1-\varepsilon)}^{\pi(1-\varepsilon)} \frac{\partial^{k}}{\partial t^{k}} \left( e^{-ixt} (\widehat{L}_{\alpha,c}(t) - 1) \right) d\mu(t)$$

$$+ \int_{-\pi(1-\varepsilon)}^{\pi(1-\varepsilon)} \frac{\partial^{k}}{\partial t^{k}} \left( \sum_{j \neq 0} \widehat{L}_{\alpha,c}(t + 2\pi j) e^{-ix(t+2\pi j)} \right) d\mu(t)$$

$$= : \int_{-\pi(1-\varepsilon)}^{\pi(1-\varepsilon)} I_{1,c}(t) d\mu(t) + \int_{-\pi(1-\varepsilon)}^{\pi(1-\varepsilon)} I_{2,c}(t) d\mu(t).$$

By applying the Leibniz rule,

$$I_{2,c}(t) = (-ix)^{k} e^{-ixt} \left( \widehat{L}_{\alpha,c}(t) - 1 \right) + \sum_{j=0}^{k-1} \binom{k}{j} (-ix)^{k-j} e^{-ixt} \widehat{L}_{\alpha,c}^{(j)}(t).$$

The first term above converges to 0 uniformly for $|t| \leq \pi(1-\varepsilon)$, which can be seen from the last portion of the proof of Proposition 3. Additionally, by Proposition 5(i) the second term above is bounded above by

$$\sum_{j=0}^{k-j} A_{k,M,\varepsilon,\alpha} c^{2j(2\alpha-\lfloor \alpha \rfloor) + j} e^{-2\pi c \varepsilon},$$

and hence converges uniformly to 0 as $c \to \infty$.

Similarly, write

$$I_{2,c}(t) = \sum_{j=0}^{k} \binom{k}{j} (-ix)^{k-j} e^{-ixt} \left[ \sum_{l \neq 0} e^{-i2\pi xl} \widehat{L}_{\alpha,c}(t + 2\pi l) \right].$$

Here, if $|t| \leq \pi(1-\varepsilon)$, then whenever $l = \pm 1$ and $|l| \geq 2$, $|t + 2\pi l|$ falls into the respective ranges for Proposition 5(ii) and (iii). Applying the estimates of that proposition demonstrates that $I_{2,c}(t) \to 0$ uniformly as $c \to \infty$ for $|x| \leq M$.

If $k = 0$, then we again split the integral into two pieces, and analyze the corresponding integrands $I_{1,c}$ and $I_{2,c}$. However, notice that there are no terms of the form $(ix)^{l}$, and so the inequalities from Proposition 5 give upper bounds on the integrands that do not depend on $x$ at all, and so the convergence of $\mathcal{I}_{\alpha,c}$ to $f$ is uniform on $\mathbb{R}$. \qed

The condition on the support of the measure $\mu$ in the previous Theorem was essential because of the use of Proposition 5 in the proof. Heuristically, the condition on the support should be of no surprise due to the fact that we have no uniform control (in $c$) of the derivatives of $\widehat{L}_{\alpha,c}$ at the boundary points $\pm \pi$. In fact, it is likely that the derivatives get much larger near the boundary as $c$ grows, especially given the fact
that \( \hat{L}_{\alpha,c} \) converges to the characteristic function of \((-\pi, \pi)\). Nevertheless, we may make a weaker assumption on \( \mu \) which still yields a convergence result.

**Theorem 14** Suppose \( \alpha \) is as above, and \( f \) is given by

\[
f(x) := \int_{-\pi}^{\pi} e^{-ixt} d\mu(t), \quad x \in \mathbb{R},
\]

for some \( \mu \in M(\mathbb{T}) \) which is absolutely continuous with respect to the Lebesgue measure. Then

\[
\lim_{c \to \infty} \mathcal{I}_{\alpha,c} f(x) = f(x), \quad x \in \mathbb{R},
\]

with convergence being uniform on \( \mathbb{R} \).

**Proof** The proof is quite similar to that of Theorem 13. Let \( \gamma > 0 \) be arbitrary, and choose \( \varepsilon > 0 \) such that \(|\mu|[-\pi, -\pi(1 - \varepsilon)] + |\mu|[\pi(1 - \varepsilon), \pi] < \gamma \) since \(|\mu|\) is absolutely continuous with respect to the Lebesgue measure. Then, as before,

\[
\mathcal{I}_{\alpha,c} f(x) - f(x) = \int_{-\pi}^{\pi} e^{-ixt} (\hat{L}_{\alpha,c}(t) - 1) d\mu(t)
\]

\[
+ \int_{-\pi}^{\pi} \left( \sum_{j \neq 0} \hat{L}_{\alpha,c}(t + 2\pi j)e^{-ix(t+2\pi j)} \right) d\mu(t). \quad (38)
\]

Split each integral into one over \([-\pi(1 - \varepsilon), \pi(1 - \varepsilon)] \) and one near the endpoints. The integral over the interior segment can be handled exactly as in the proof of Theorem 13. For the integrals near the endpoints, notice that \(|e^{-ixt}(\hat{L}_{\alpha,c}(t) - 1)| \leq 2\), and so the first integral is at most \(2(|\mu|[-\pi, -\pi(1 - \varepsilon)] + |\mu|[\pi(1 - \varepsilon), \pi])\), which is at most \(2\gamma\) by the choice of \( \varepsilon \). Meanwhile, by Proposition 5(iii), the second integrand is at most

\[
2 + \sum_{|j| \geq 2} |\hat{L}_{\alpha,c}(t + 2\pi j)| \leq 2 + A_\alpha \sum_{|j| \geq 2} c^{2\alpha - |\alpha|} e^{-2\pi c(|j|-1)},
\]

which can be bounded by a constant depending only on \( \alpha \). Thus \(|\mathcal{I}_{\alpha,c} f(x) - f(x)| \leq A_\alpha \gamma\) for some constant \( A_\alpha \) independent of \( c \), and so the conclusion follows.

**Remark 1** We conclude this section with the special consideration of the case \( \alpha = -1 \), where \( \phi_{\alpha,c} \) is called the Poisson kernel. As mentioned above, the fundamental function for the Poisson kernel, \( L_{-1,c} \), decays faster than any polynomial. Thus any results in this section that depend on the decay rate of the fundamental function hold true for the Poisson kernel. In particular, Propositions 6 and 7, and Theorems 8, 9, 10, 11, and 14 are all valid for the Poisson kernel, since existence of the interpolant primarily depends on the decay of the fundamental function.

Moreover, because the fundamental function for the Poisson kernel decays so rapidly, we find much stronger versions of the results in this section.

We begin by stating the analogue of Theorem 7.
Theorem 15 Suppose that
\[ |y_j| \leq A(1 + |j|^k), \quad j \in \mathbb{Z} \]
for some \( k \in \mathbb{N}_0 \) and constant \( A \). Then the cardinal Poisson interpolant,
\[ \mathcal{I}_{-1,c}y(x) := \sum_{j \in \mathbb{Z}} y_j L_{-1,c}(x - j), \quad y = (y_j)_{j \in \mathbb{Z}}, \]
is well-defined, continuous on \( \mathbb{R} \), and satisfies \( \mathcal{I}_{-1,c}y(x) = O(1 + |x|^l), \quad |x| \to \infty \) for any \( l \geq k \).

As a consequence of the preceding theorem, the function \( \Phi_{-1,c} \) defined by Eq. 29 has well-defined derivatives of all orders. In particular, Lemma 5 holds, and consequently we find the following analogue of Theorem 12.

Theorem 16 Suppose \( f \) is given by
\[ f(x) := (ix)^k \int_{-\pi}^{\pi} e^{-ixt} d\mu(t), \]
for some \( \mu \in M(\mathbb{T}) \) and some \( k \in \mathbb{N}_0 \). Then
\[ \mathcal{I}_{-1,c}f(x) = \int_{-\pi}^{\pi} \Phi_{-1,c}^{(k)}(x, t)d\mu(t), \quad c > 0, \quad x \in \mathbb{R}. \]

Finally, Theorem 13 holds for any \( k \in \mathbb{N}_0 \) for the Poisson kernel.

6 Convergence examples

In this section, we illustrate the convergence phenomena discussed in the previous section. The examples are of a similar flavor to those found in [29].

Example 1 Let \( \alpha \in [1/2, \infty) \setminus \mathbb{N} \) and \( k \in \{0, 1, \ldots, [2\alpha + 1] - 2\} \), or \( \alpha \in (-\infty, -3/2) \) and \( k \in \{0, 1, \ldots, [2|\alpha| - 2] - 2\} \), or \( \alpha = -1 \) and \( k \in \mathbb{N}_0 \). Let \( \mu_k \) be the \( 2\pi \)-periodic extension of the measure \( i^k \delta_0 \), where \( \delta_0 \) is the usual Dirac measure at 0. If
\[ f_k(x) := (-ix)^k \int_{-\pi}^{\pi} e^{-ixt} d\mu_k(t) = x^k, \quad x \in \mathbb{R}, \]
then Theorem 13 implies that \( \lim_{c \to \infty} \mathcal{I}_{\alpha,c}f_k(x) = f_k(x) \) uniformly on compact subsets of \( \mathbb{R} \).

However, Theorem 6 allows us to say more given this information. If \( k = 0 \), then we find the following identity on account of Theorem 12:
\[ \mathcal{I}_{\alpha,c}f_0(x) = \Phi_{\alpha,c}(x, 0) = \sum_{j \in \mathbb{Z}} \widehat{L}_{\alpha,c}(2\pi j) e^{-ix2\pi j} = 1. \quad (39) \]
For higher order polynomials, we may use Theorems 12 and 13 to show that

$$J_{\alpha, cfk}(x) - x^k = i^k \sum_{l=0}^{k-1} \sum_{j \in \mathbb{Z}} L_{\alpha, c}^{(k-l)}(2\pi j)(-ix)^l e^{-ix2\pi j},$$

whereby one can obtain an error bound in terms of $c$ via Proposition 5. This also demonstrates that $J_{\alpha, cfk} \to f_k$ uniformly on compact subsets of $\mathbb{R}$.

**Example 2** Let $0 < a \leq \pi$ be fixed, and let $\mu$ be the $2\pi$-periodic extension of $1/2a \chi_{[-a,a]}dt$, where $\chi_{[-a,a]}$ takes value 1 on $[-a, a]$ and 0 elsewhere. Define

$$f(x) = \int_{-\pi}^{\pi} e^{-ixt} d\mu(t) = \frac{1}{2a} \frac{\sin(ax)}{ax}, \ x \in \mathbb{R}.$$

Since $\mu$ is absolutely continuous with respect to the Lebesgue measure, Theorem 14 implies that $J_{\alpha, cf} \to f$ uniformly on $\mathbb{R}$. Note that this fact also follows from Theorem 1, albeit from substantially different reasoning. However, the hypothesis of Theorem 1 requires the function being interpolated to be bandlimited, and so the following result cannot be obtained simply by appealing to that theorem.

**Example 3** Let $\alpha$ and $k$ be as in Example 1. Let $\mu_k$ be the periodic extension of $i^k 1/2a \chi_{[-a,a]}dt$ for some $a < \pi$. Then if

$$g_k(x) := (-ix)^k \int_{-\pi}^{\pi} e^{-ixt} d\mu_k(t) = x^k \frac{\sin(ax)}{ax}, \ x \in \mathbb{R},$$

Theorem 13 implies that $\lim_{c \to \infty} J_{\alpha, cgk}(x) = g_k(x)$, uniformly on compact subsets of $\mathbb{R}$.

### 7 Proofs for section 4

In this section we prove the various results listed in Section 4. Our methods closely resemble those found in [29]. To reduce the clutter in our calculations, we will henceforth drop explicit dependence upon $\alpha$ in our calculations that follow. We begin by rewriting Eq. 4 in terms of a Laplace transform to exhibit the singularity at the origin. To do this, we require an integral representation for the Bessel function, which we find in [32, p.185]:

$$K_v(r) = \frac{\Gamma\left(\frac{1}{2}\right)r^v}{2^v\Gamma(v + \frac{1}{2})} \int_1^\infty e^{-rx}(x^2 - 1)^{v-\frac{1}{2}} dx, \ v \geq 0, r > 0. \quad (40)$$

Consequently, putting $r = c|\xi|$ and performing the substitution $x|\xi| = t + |\xi|$ yields the following on account of Eq. 4.

$$\hat{\phi}_c(\xi) = A_{\alpha} c^{2\alpha+1}|\xi|^{-2\alpha-1} e^{-c|\xi|} \int_0^\infty e^{-ct} t^\alpha (t + 2|\xi|)^\alpha dt, \quad (41)$$
where $A_\alpha$ is a constant. We relabel the product of the exponential and the integral in the above expression $F_\alpha$. That is,

$$F_\alpha(\xi) := e^{-c|\xi|} \int_0^\infty e^{-ct} t^\alpha (t + 2|\xi|)^\alpha dt,$$

hence Eq. 41 may be abbreviated as

$$\hat{\phi}_c(\xi) = A_\alpha c^{2\alpha+1} |\xi|^{-2\alpha-1} F_\alpha(\xi).$$

(43)

For $\alpha < -1$, we have

$$\hat{\phi}_c(\xi) = A_\alpha F|\alpha|-1(\xi).$$

(44)

We turn our attention to the estimates involving $F_\alpha$ and its derivatives, and begin by noting that

$$F_\alpha(\xi) = e^{-c|\xi|} \mathcal{L}[t^\alpha (t + 2|\xi|)^\alpha](c),$$

(45)

where $\mathcal{L}$ denotes the usual Laplace transform, $\mathcal{L}[f](s) = \int_0^\infty f(t) e^{-st} dt$. Our estimates for $F_\alpha$ will rely on estimates for the Laplace transform. The first result in this direction is a lower bound.

**Lemma 6** For $\alpha > 0$,

$$\mathcal{L}[t^\alpha (t + 2|\xi|)^\alpha](c) \geq \max \left\{ \frac{(2|\xi|)^\alpha \Gamma(\alpha + 1)}{c^{\alpha+1}}, \frac{\Gamma(2\alpha + 1)}{c^{2\alpha+1}} \right\}.$$  

(46)

**Proof** We obtain this bound by combining the inequalities

$$\mathcal{L}[t^\alpha (t + 2|\xi|)^\alpha](c) \geq \int_0^\infty e^{-ct} (2|\xi|)^\alpha t^\alpha dt = \frac{(2|\xi|)^\alpha \Gamma(\alpha + 1)}{c^{\alpha+1}}$$

and

$$\mathcal{L}[t^\alpha (t + 2|\xi|)^\alpha](c) \geq \int_0^\infty e^{-ct} t^{2\alpha} dt = \frac{\Gamma(2\alpha + 1)}{c^{2\alpha+1}}.$$ 

We state the upper bounds in the following lemma.

**Lemma 7** For $\alpha \in (0, \infty) \setminus \mathbb{N}$ and $l \in \mathbb{N}_0$, the following estimates hold for the Laplace transform $\mathcal{L}[t^\alpha (t + 2|\xi|)^{\alpha-l}](c)$.

(i) If $0 \leq l < |\alpha|$, 

$$\left| \mathcal{L}[t^\alpha (t + 2|\xi|)^{\alpha-l}](c) \right| \leq \frac{(4|\xi|)^{\alpha-l} \Gamma(\alpha + 1)}{c^{\alpha+1} + \frac{2^{\alpha-l} \Gamma(2\alpha + 1 - l)}{c^{2\alpha+1-l}}};$$

(ii) if $|\alpha| < l < 2\alpha + 1$, 

$$\left| \mathcal{L}[t^\alpha (t + 2|\xi|)^{\alpha-l}](c) \right| \leq \frac{2^{3\alpha-2l}|\xi|^{2\alpha-l}}{c} + \frac{2^{\alpha-l} \Gamma(2\alpha + 1 - l)}{c^{2\alpha+1-l}};$$

(iii) if $l = 2\alpha + 1$ (thus $\alpha$ is an odd half integer), 

$$\left| \mathcal{L}[t^\alpha (t + 2|\xi|)^{\alpha-l}](c) \right| \leq \ln \left( 1 + |\xi|^{-1} \right) + \frac{e^{-c}}{c(1 + |\xi|)}$$.
Proof For (i), we have the following

\[
\mathcal{L}[t^\alpha(t + 2|\xi|)^{\alpha-l}](c) = \int_0^{2|\xi|} e^{-ct} t^\alpha(t + 2|\xi|)^{\alpha-l} dt + \int_0^\infty e^{-ct} t^\alpha(t + 2|\xi|)^{\alpha-l} dt
\]

\[
\leq \int_0^{2|\xi|} e^{-ct} t^\alpha(4|\xi|)^{\alpha-l} dt + \int_0^\infty e^{-ct} t^\alpha(2t)^{\alpha-l} dt
\]

\[
\leq \frac{(4|\xi|)^{\alpha-l} \Gamma(\alpha+1)}{c^{\alpha+1}} + \frac{2^{\alpha-l} \Gamma(2\alpha+1-l)}{c^{2\alpha+1-l}}.
\]

Inequality (ii) follows from a similar calculation, replacing \(t\) with \(2|\xi|\) in the first integral below:

\[
\mathcal{L}[t^\alpha(t + 2|\xi|)^{\alpha-l}](c) = \int_0^{2|\xi|} e^{-ct} t^\alpha(t + 2|\xi|)^{\alpha-l} dt + \int_0^\infty e^{-ct} t^\alpha(t + 2|\xi|)^{\alpha-l} dt
\]

\[
\leq \int_0^{2|\xi|} e^{-ct} 2^{3\alpha-2|\xi|} 2^{\alpha-l} dt + \int_0^\infty e^{-ct} 2^{\alpha-l} 2^{\alpha-l} dt
\]

\[
\leq \frac{2^{3\alpha-2|\xi|} |\xi|^{2\alpha-l}}{c} + \frac{2^{\alpha-l} \Gamma(2\alpha+1-l)}{c^{2\alpha+1-l}}.
\]

Finally, for inequality (iii), we have

\[
\mathcal{L}[t^\alpha(t + 2|\xi|)^{-\alpha-1}](c) = \int_0^\infty e^{-ct} \frac{t^\alpha}{(t + 2|\xi|)^{\alpha+1}} dt = \int_0^\infty e^{-ct} \frac{t^\alpha}{(t + 2|\xi|)^{\alpha+1}} dt
\]

\[
= \int_0^{1|\xi|^{-1}} e^{-ct|\xi|} \frac{t^\alpha}{(t + 2|\xi|)^{\alpha+1}} dt + \int_0^\infty e^{-ct|\xi|} \frac{t^\alpha}{(t + 2|\xi|)^{\alpha+1}} dt
\]

\[
\leq \int_0^{1|\xi|^{-1}} 1 + t^{-1} dt + \int_0^\infty e^{-ct|\xi|} (1 + t^{-1}) dt
\]

\[
\leq \ln\left(1 + |\xi|^{-1}\right) + \frac{e^{-c}}{c(1 + |\xi|)} \leq \ln\left(1 + |\xi|^{-1}\right) + \frac{e^{-c}}{c}.
\]

Thus we have the following Lemma which allows us to easily bound the derivatives of \(F_\alpha\).

**Lemma 8** For \(\alpha > 0\), and \(0 \leq k \leq 2\alpha + 1\),

\[
|F_\alpha^{(k)}(\xi)| \leq e^{-c|\xi|} \sum_{l=0}^k A_{k,l,\alpha} c^{k-l} \mathcal{L}[t^\alpha(t + 2|\xi|)^{\alpha-l}](c),
\]

where \(A_{k,l,\alpha}\) are constants independent of \(c\).

Proof Applying the Leibniz rule to Eq. 42, we see that

\[
|F_\alpha^{(k)}(\xi)| = e^{-c|\xi|} \sum_{l=0}^k A_{k,l,\alpha} c^{k-l} \frac{d^l}{d\xi^l} \left(\mathcal{L}[t^\alpha(t + 2|\xi|)^{\alpha}](c)\right)(\xi).
\]
Differentiating under the integral sign, which is justified by the exponential decay of the integrand, and using the triangle inequality yield Eq. 47.

**Remark 2** Lemmas 7 and 8 combine to show that for $0 \leq k < 2\alpha + 1$, $F^{(k)}_\alpha$ has no singularities, while for $k = 2\alpha + 1$, a logarithmic singularity is introduced at the origin.

Our next lemma establishes pointwise estimates for the derivatives of both $\hat{\phi}_c$ and $1/\hat{\phi}_c$.

**Lemma 9** Suppose $\alpha > 0$ and $c \geq 1$. If $0 \leq k \leq 2\alpha + 1$, then we have

\[ |\hat{\phi}_c^{(k)}(\xi)| \leq c^{2\alpha + 1} |\xi|^{-2\alpha - 1 - k} e^{-c|\xi|} \sum_{l=0}^{k} \sum_{l'=0}^{k} A_{k,l,l',\alpha} c^{l-l'} |\xi|^l \mathcal{L}[t^{\alpha}(t + 2|\xi|)^{\alpha-l'}](c) \]

and

\[ |(1/\hat{\phi}_c)^{(k)}(\xi)| \leq A_{k,\alpha} c^{k(2\alpha + 1 - \lfloor \alpha \rfloor)} e^{c|\xi|} |\xi|^{2\alpha + 1 - k} [1 + O(1)], \text{ as } |\xi| \to 0. \]

Here $A_{k,l,l',\alpha}$ and $A_{k,\alpha}$ are positive constants.

**Proof** To see (i), apply the Leibniz rule, triangle inequality, and Lemma 8 to Eq. 43. As a prelude to (ii), we remark that combining (i) with Lemma 7 (i) and (ii) reveals that if $0 \leq k < 2\alpha + 1$,

\[ |\hat{\phi}_c^{(k)}(\xi)| \leq A_{\alpha} c^{2\alpha - \lfloor \alpha \rfloor + k} |\xi|^{-2\alpha - 1 - k} e^{-c|\xi|} [1 + O(1)], \quad |\xi| \to 0. \tag{48} \]

If $k = 2\alpha + 1$, we pick up an extra singularity from Lemma 7 (iii), in which case we split the double sum in (i) into three parts, the first of which corresponds to $l' = l = k$, the second to $l' < l$, $l = k$, and the third to $l' \leq l, l < k$:

\[
|\hat{\phi}_c^{(k)}(\xi)| \leq A_{\alpha} c^{2\alpha + 1 - \lfloor \alpha \rfloor} e^{-c|\xi|} |\xi|^{-4\alpha - 2} \sum_{l=0}^{k} \sum_{l'=0}^{k} A_{k,l,l',\alpha} c^{l-l'} |\xi|^l \mathcal{L}[t^{\alpha}(t + 2|\xi|)^{\alpha-l'}](c)
\]

\[ = A_{\alpha} c^{2\alpha + 1} e^{-c|\xi|} |\xi|^{-4\alpha - 2} \left( |\xi|^{2\alpha + 1} \ln(1 + |\xi|) \right)
\]

\[ + \sum_{l'=0}^{k-1} A_{k,l',\alpha} c^{2\alpha + 1 - l'} |\xi|^{2\alpha + 1} \mathcal{L}[t^{\alpha}(t + 2|\xi|)^{\alpha-l'}](c)
\]

\[ + \sum_{l=0}^{k-1} \sum_{l'=0}^{l} A_{k,l,l',\alpha} c^{l-l'} |\xi|^l \mathcal{L}[t^{\alpha}(t + 2|\xi|)^{\alpha-l'}](c)
\]

\[ \leq A_{\alpha} c^{4\alpha + 1 - \lfloor \alpha \rfloor} e^{-c|\xi|} |\xi|^{-2\alpha - 1} \ln(1 + |\xi|) + A_{\alpha} c^{4\alpha + 1 - \lfloor \alpha \rfloor} e^{-c|\xi|} |\xi|^{-4\alpha - 2} [1 + O(1)], \quad |\xi| \to 0. \tag{49} \]

To track the largest powers of $c$, we note that there is nothing to do in the logarithmic term; in the second term we use Lemma 7 and take $l' = \lfloor \alpha \rfloor$ to obtain $c^{4\alpha + 1 - \lfloor \alpha \rfloor}$; for the third term we let $l = 2\alpha$ and $l' = \lfloor \alpha \rfloor$ to obtain $c^{4\alpha - \lfloor \alpha \rfloor}$.
To prove (ii), we again apply the Leibniz rule to obtain

\[
(1/\hat{\phi}_c)^{(k)}(\xi) = (\hat{\phi}_c(\xi))^{-k-1} \sum_{\gamma \in \Gamma_k} A_\gamma \prod_{l=1}^k \hat{\phi}_c^{(\gamma_l)}(\xi),
\]

where \( \Gamma_k \) is the set of increasing non-negative integer partitions of \( k \), that is, \( \Gamma_k = \{ (\gamma_1, \ldots, \gamma_k) \in \mathbb{N}_0^k : \gamma_l \leq \gamma_{l+1}, \sum \gamma_l = k \} \). For \( 0 \leq k < 2\alpha + 1 \), we may plug Eqs. 43, 47, and 48 into Eq. 50 to obtain:

\[
\left| (1/\hat{\phi}_c)^{(k)}(\xi) \right| \leq A_\alpha c^{- (2\alpha + 1)(k+1)} |\xi|^{2\alpha+1-k} (F_\alpha(\xi))^{-k-1} \\
\times \sum_{\gamma \in \Gamma_k} A_\gamma \prod_{l=1}^k e^{2\alpha+\gamma_l-\lfloor \alpha \rfloor} |\xi|^{-2\alpha-1-\gamma_l} e^{-c|\xi|} \left[ 1 + O(1) \right], \quad |\xi| \to 0.
\]

Now applying Eq. 46 and collecting terms provides the desired estimate

\[
\left| (1/\hat{\phi}_c)^{(k)}(\xi) \right| \leq A_{\alpha, k} c^{2\alpha+1} e^{c|\xi|} |\xi|^{2\alpha+1-k} \left[ 1 + O(1) \right], \quad |\xi| \to 0.
\]

If \( k = 2\alpha + 1 \), then the logarithmic singularity in Eq. 49 appears only when \( \gamma = (0, \ldots, 0, k) \). By using Eq. 46, we see that the corresponding term satisfies

\[
\left| \frac{\hat{\phi}_c^{(k)}(\xi)}{\hat{\phi}_c(\xi)} \right| \leq A_\alpha c^{2\alpha+1} e^{c|\xi|} |\xi|^{2\alpha+1} \ln(1 + |\xi|^{-1}) + A_\alpha c^{4\alpha+1-\lfloor \alpha \rfloor} e^{c|\xi|} \left[ 1 + O(1) \right] \\
= A_\alpha c^{2\alpha+1} e^{c|\xi|} o(1) + A_\alpha c^{4\alpha+1-\lfloor \alpha \rfloor} e^{c|\xi|} \left[ 1 + O(1) \right], \quad |\xi| \to 0.
\]

Thus the term containing the logarithmic singularity is bounded by the estimate in Eq. 52, and the proof is complete.

Remark 3 The calculations above show that for \( 0 \leq k \leq 2\alpha + 1 \), \( (1/\hat{\phi}_c)^{(k)} \in L_{\infty}[-\pi, \pi] \).

We are now in position to prove Proposition 4.

Proof of Proposition 4 Recall that for \( j \neq 0 \), \( a_j(\xi) = \hat{\phi}_c(\xi + 2\pi j)/\hat{\phi}_c(\xi) \). From the Leibniz rule, we have

\[
a_j^{(k)}(\xi) = \sum_{l=0}^k A_{k,l} \left( (1/\hat{\phi}_c)^{(l)}(\xi) \hat{\phi}_c^{(k-l)}(\xi + 2\pi j) \right).
\]

Thus we may use Eqs. 48 and 52 to obtain

\[
|a_j^{(k)}(\xi)| \leq g(\xi) \sum_{l=0}^k A_{k,l} e^{(l+1)(2\alpha-\lfloor \alpha \rfloor)+k} e^{c|\xi|} |\xi|^{-2\alpha-1} e^{-c|\xi|} |\xi|^{2\alpha+1-l} \left| \xi + 2\pi j \right|^{-(2\alpha+1+k-l)},
\]
where \( g \in L_{\infty}[-\pi, \pi] \). Since \(|\xi| \leq \pi (1 - \varepsilon)\), \(|\xi + 2\pi j| - |\xi| \geq 2\pi(|j| - 1 + \varepsilon)\), and \(|\xi + 2\pi j| \geq \pi (1 + \varepsilon)\), we have

\[
|a_j^{(k)}(\xi)| \leq c^{(k+1)(2\alpha - |\alpha|) + k} e^{-2\pi c \varepsilon} e^{-2\pi c(|j| - 1)} \sum_{l=0}^{k} A_{k,l,\alpha} \frac{(\pi (1 - \varepsilon))^{2\alpha + 1 - l}}{(\pi (1 + \varepsilon))^{2\alpha + 1 + k - l}}.
\]

This is the desired estimate for \(1 \leq k < 2\alpha + 1\). If \( k = 2\alpha + 1 \), we must use Eqs. 49 and 53 to handle the logarithmic term. This changes \( \Lambda_{\alpha}(\varepsilon) \); however, it is still true that \( \Lambda_{\alpha}(\varepsilon) = O(1) \) as \( \varepsilon \to 0 \). \(\square\)

An immediate consequence of Proposition 4 is that the function \( s_c \) defined in Eq. 14 converges for \(|\xi| \leq \pi (1 - \varepsilon)\) and we can differentiate the series term by term. In fact, by applying the estimates from Eq. 15, we have

\[
|s_c^{(k)}(\xi)| \leq A_{k,\alpha}(\varepsilon)c^{(k+1)(2\alpha - |\alpha|) + k} e^{-2\pi c \varepsilon}, \quad (55)
\]

for \(0 \leq k \leq 2\alpha + 1\) and \(|\xi| \leq \pi (1 - \varepsilon)\), where \( A_{k,\alpha}(\varepsilon) = O(1) \) as \( \varepsilon \to 0 \).

Recalling that \( \hat{L}_c(\xi) = (1 + s_c(\xi))^{-1} \), we may prove pointwise bounds for \( \hat{L}_c^{(k)} \) by applying Eq. 55 in a similar manner to Eq. 50. The next three lemmas prove Proposition 5.

**Lemma 10** Let \( \varepsilon \in [0, 1) \) and suppose that \(|\xi| \leq \pi (1 - \varepsilon)\). If \(0 \leq k \leq 2\alpha + 1\), then

\[
|\hat{L}_c^{(k)}(\xi)| \leq A_{k,\alpha}(\varepsilon)c^{(2\alpha - |\alpha|) + k} e^{-2\pi c \varepsilon}, \quad (56)
\]

where \( A_{k,\alpha}(\varepsilon) = O(1) \) as \( \varepsilon \to 0 \).

Analogous to the argument given in [29], we find that if \(|j| \geq 2\) and \(\xi \in [(-2j - 1)\pi, (-2j + 1)\pi]\), then

\[
\hat{L}_c(\xi) = a_{-j}(r) \hat{L}_c(r),
\]

where \( r = 2\pi j + \xi \). This means that \( r \in [-\pi, \pi] \), so we may use the Leibniz rule together with Proposition 4 and Lemma 10 (letting \( \varepsilon = 0 \)) to obtain our next result.

**Lemma 11** Let \(0 \leq k \leq 2\alpha + 1\). If \(|j| \geq 2\) and \(\xi \in [(-2j - 1)\pi, (-2j + 1)\pi]\), then

\[
|\hat{L}_c^{(k)}(\xi)| \leq A_{k,\alpha}(\varepsilon)c^{(2k+1)(2\alpha - |\alpha|) + k} e^{-2\pi c |j| - 1}, \quad (57)
\]

where \( A_{k,\alpha} \) is independent of both \( c \) and \( j \).

Our final estimate is for the region \(|\xi| \in [(1 + \varepsilon)\pi, 3\pi] \). For these intervals, we adapt the argument given for Theorem 2.4 in [29].

**Lemma 12** Let \( \varepsilon \in [0, 1) \) and \(0 \leq k \leq 2\alpha + 1\). If \(|\xi| \in [(1 + \varepsilon)\pi, 3\pi]\), then

\[
|\hat{L}_c^{(k)}(\xi)| \leq A_{k,\alpha}(\varepsilon)c^{(2k+1)(2\alpha - |\alpha|) + k} e^{-\pi c \varepsilon}, \quad (58)
\]

where \( A_{k,\alpha}(\varepsilon) = O(1) \) as \( \varepsilon \to 0 \).

**Proof of Theorem 2** Applying the pointwise estimates from Proposition 5 establishes the \( L_1 \) bound. \(\square\)
Proof of Theorem 3 Using Eq. 44 and replacing $F_\alpha$ with $F_{|\alpha|-1}$ one obtains the stated bounds by using reasoning similar to that used to establish Theorem 2.

Proof of Theorem 4 In the special case of $\alpha = -1$, we get the Poisson kernel, whose Fourier transform is given by

$$\hat{\phi}_c(\xi) = A F_0(\xi) = (A/c)e^{-c|\xi|}.$$  

Using this much simpler formula allow us to simplify our earlier work and get stronger results. In fact, we see that the analogue of Proposition 4 is given by

$$|a_j^{(k)}(\xi)| \leq A c^k e^{-c|\xi|+2\pi j},$$

where there is no longer a restriction on $k \in \mathbb{N}_0$. The proof of Theorem 4 now follows the same line of reasoning as that used to prove Theorem 2.

Proof of Theorem 5 We begin by noting that $\hat{L}_c$ is even, so we need only consider the integral

$$\int_0^\infty |\hat{L}_c'(\xi)|d\xi = \int_0^{\pi/2} |\hat{L}_c'(\xi)|d\xi + \int_{\pi/2}^{3\pi/2} |\hat{L}_c'(\xi)|d\xi + \int_{3\pi/2}^\infty |\hat{L}_c'(\xi)|d\xi =: I + II + III.$$

For $I$, we use Lemma 10 with $\varepsilon = 1/2$ and find that $I \leq A_a e^{c(2\alpha - |\alpha|)+1}e^{-\pi c} \leq A'_a$. The quantity $III$ may be estimated similarly using Lemmas 11 and 12 (and again letting $\varepsilon = 1/2$). We have

$$III \leq A_a e^{c(2\alpha - |\alpha|)+1} \left( e^{-\pi c/2} + \sum_{j=1}^\infty e^{-2\pi cj} \right) \leq A'_a.$$

The last inequality follows from the fact that both terms in parentheses have a global maximum which depends only on $\alpha$. Finally, we show that $L_c$ is monotone on $[\pi/2, 3\pi/2]$, which implies that $II = |L_c(\pi/2) - L_c(3\pi/2)| \leq 1$. To that end, we use the quotient rule to write

$$\hat{L}_c'(\xi) = \frac{\sum_{j \neq 0} \left\{ \hat{\phi}_c(\xi)\hat{\phi}_c(\xi + 2\pi j) - \hat{\phi}_c(\xi)\hat{\phi}_c'(\xi + 2\pi j) \right\}}{\left( \sum_{j \in \mathbb{Z}} \hat{\phi}_c(\xi + 2\pi j) \right)^2}.$$
We recall that \( \hat{\phi}_c(\xi) = A_\alpha c^{\alpha+1/2}|\xi|^{-\alpha-1/2}K_{\alpha+1/2}(c|\xi|) \), and by the formula found in [1, p. 361], \( \hat{\phi}_c(\xi) = -A_\alpha c^{\alpha+3/2}\text{sgn}(\xi)|\xi|^{-\alpha-1/2}K_{\alpha+3/2}(c|\xi|) \). These allow us to rewrite the numerator,

\[
\sum_{j \neq 0} \left\{ \hat{\phi}_c'(\xi)\hat{\phi}_c(\xi + 2\pi j) - \hat{\phi}_c(\xi)\hat{\phi}_c'(\xi + 2\pi j) \right\} = A_\alpha^2c^{2\alpha+2}|\xi|^{-\alpha-1/2} \\
\times \left\{ g_1(\xi)K_{\alpha+1/2}(c|\xi|) - g_2(\xi)K_{\alpha+3/2}(c|\xi|) \right\},
\]

where

\[
g_1(\xi) = \sum_{j=1}^{\infty} \left( (2\pi j + \xi)^{-\alpha-1/2}K_{\alpha+3/2}(c(2\pi j + \xi)) \right. \\
- (2\pi j - \xi)^{-\alpha-1/2}K_{\alpha+3/2}(c(2\pi j - \xi)) \right),
\]

\[
g_2(\xi) = \sum_{j=1}^{\infty} \left( (2\pi j + \xi)^{-\alpha-1/2}K_{\alpha+1/2}(c(2\pi j + \xi)) \right. \\
+ (2\pi j - \xi)^{-\alpha-1/2}K_{\alpha+1/2}(c(2\pi j - \xi)) \right).
\]

From these expressions, we see that \( g_2(\xi) > 0 \) for \( \xi \in [\pi/2, 3\pi/2] \) and \( g_1(\xi) < 0 \) on \( [\pi/2, 3\pi/2] \). The latter is true since \( f(x) = x^{-\alpha-1/2}K_{\alpha+3/2}(x) \) is decreasing. This shows that \( \hat{L}_c \) is decreasing on \( [\pi/2, 3\pi/2] \) as desired.

**Proof of Lemma 4** Recall that \( \hat{L}_c \) is non-negative as commented in Section 3, and Theorems 2 and 3 show that \( L_c \) is continuous and integrable for the given range of \( \alpha \). Consequently, \( L_c \) is positive definite, and thus for every \( x \in \mathbb{R}, \)
\[
|L_c(x)| \leq |L_c(0)| = 1,
\]
the final equality coming from Eq. 8.

We end the section with the proof of Theorem 6.

**Proof of Theorem 6** We first consider the case \( k = 0 \). As in Section 3, write \( \hat{L}_c(\xi) = (1 + \sum_{j \neq 0} a_j(\xi))^{-1} \). Proposition 4 with \( \varepsilon = 0 \) implies that the series converges uniformly for \( |\xi| \leq \pi \). Consequently, \( \hat{L}_c(0) = \lim_{\xi \to 0} \hat{L}_c(\xi) = 1 \). To see that this limit is 1 requires estimating \( \hat{L}_c(\xi) \) in a slightly different manner than we have so far. Combining Eqs. 43 and 45, we estimate

\[
\sum_{j \in \mathbb{Z}} |a_j(\xi)| \leq \sum_{j \neq 0} \left| \frac{\xi}{\xi + 2\pi j} \right|^{2\alpha+1} e^{-c(|\xi+2\pi j|{-|\xi|})} \left| \frac{\hat{L}[t^\alpha(t + 2|\xi + 2\pi j|)\alpha](c)}{\hat{L}[t^\alpha(t + 2|\xi|)\alpha](c)} \right|,
\]

which by Lemma 6 and Proposition 7(i) is at most

\[
|\xi|^{2\alpha+1}\sum_{j \neq 0} \frac{1}{|\xi + 2\pi j|^{2\alpha+1}} e^{-c(|\xi+2\pi j|{-|\xi|})} \left( \frac{4\Gamma(\alpha + 1)}{\Gamma(2\alpha + 1)} \right) c |\xi + 2\pi j|\alpha + 2\alpha.
\]

The series is summable, and uniformly bounded for \( |\xi| \leq \pi \), and it follows that

\[
\lim_{\xi \to 0} \hat{L}_c(\xi) = 1.
\]
Now for $|k| \geq 1$, let $r = 2\pi k + \xi$ with $|\xi| \leq \pi$. Then we may write

$$\hat{L}_c(r) = \frac{\hat{\phi}_c(\xi + 2\pi k)}{\hat{\phi}_c(\xi)} \left[ 1 + \sum_{j \neq -k} \frac{\hat{\phi}_c(\xi + 2\pi (k + j))}{\hat{\phi}_c(\xi)} \right]$$

$$= \frac{|\xi|^{2\alpha+1} \hat{\phi}_c(\xi + 2\pi k)}{A_{\alpha} c^{2\alpha+1} F_{\alpha}(\xi) \left[ 1 + \frac{c^{-2\alpha-1} |\xi|^{2\alpha+1} \sum_{j \neq 0} \hat{\phi}_c(\xi + 2\pi j)}{F_{\alpha}(\xi)} \right]}$$

the second equality following from Eq. 43. By definition, $\lim_{\xi \to 0} F_{\alpha}(\xi) = F_{\alpha}(0) \neq 0$, and a similar argument to the case $k = 0$ above shows that we may allow $\xi$ to tend to 0, and conclude that $\hat{L}_c(2\pi k) = 0$.
