First-Line Sofia Aspiration Thrombectomy Approach within the Endovascular Treatment of Ischemic Stroke Multicentric Registry: Efficacy, Safety, and Predictive Factors of Success

G. Marnat, X. Barreau, L. Detraz, R. Bourcier, B. Gory, A. Sgreccia, F. Gariel, J. Berge, P. Menegon, M. Kyheng, J. Labreuche, A. Consoli, R. Blanc, and B. Lapergue, on behalf of the ETIS Investigators

ABSTRACT

BACKGROUND AND PURPOSE: After publication of the major trials reporting the efficacy of mechanical thrombectomy by stent retrievers in acute ischemic stroke with large-vessel occlusion, alternative endovascular approaches have been proposed using first-line aspiration catheters. Several devices are currently available to perform A Direct Aspiration First Pass Technique. The Sofia catheter aspiration has been widely used by interventionists, but data are scarce about its efficacy and safety. Our aim was to report our multicenter thrombectomy experience with first-line Sofia catheter aspiration and to identify independent prognostic factors of clinical and procedural outcomes.

MATERIALS AND METHODS: We performed a retrospective analysis of the prospectively maintained Endovascular Treatment of Ischemic Stroke multicentric registry. Data from consecutive patients who benefited from thrombectomy with a first-line Sofia approach between January 2013 and April 2018 were studied. We excluded other first-line approaches (stent retriever or combined aspiration and stent retriever) and extracranial occlusions. Baseline characteristics, procedural data, and angiographic and clinical outcomes were analyzed.

RESULTS: During the study period, 296 patients were treated. Mean age and initial NIHSS score were, respectively, 69.5 years and 16. Successful reperfusion, defined by the modified TICI 2b/3, was obtained in 86.1% (n = 255; 95% CI, 81.7%–89.9%). Complete reperfusion (modified TICI 3) was obtained in 41.2% (n = 122; 95% CI, 35.5%–47.1%). A first-pass effect was achieved in 24.2% (n = 71; 95% CI, 19.4%–29.6%). A rescue stent retriever approach was required in 29.7% (n = 88; 95% CI, 24.6%–35.3%). The complication rate was 9.5% (n = 28; 95% CI, 6.4%–13.5%). Forty-three percent (n = 122; 95% CI, 37.1%–48.9%) of patients presented with a favorable 3-month outcome (mRS ≤ 2). Older age, MI-occlusion topography, and intra venous thrombolysis use prior to thrombectomy were independent predictors of the first-pass effect.

CONCLUSIONS: The first-line contact aspiration approach appeared safe and efficient with Sofia catheters. These devices achieved very high reperfusion rates with a low requirement for stent retriever rescue therapy, especially for MI occlusions.

ABBREVIATIONS: ADAPT = A Direct Aspiration First Pass Technique; DAC = distal aspiration catheter; ETIS = Endovascular Treatment of Ischemic Stroke; FPE = first-pass effect; IQR = interquartile range; IVT = intravenous thrombolysis; mTICI = modified TICI; PH = parenchymal hematoma

After publication of the major trials reporting the efficacy of mechanical thrombectomy for large-vessel occlusion strokes, the principal concern is now to optimize recanalization rates. Recent advances in thrombectomy devices progressively enabled major improvement. In addition to stent retrievers, contact aspiration has greatly modified the endovascular approach and is now considered a routine technique. Since the A Direct Aspiration First Pass Technique (ADAPT) was described, various distal aspiration catheter (DAC) technologies have been developed. ADAPT consists of contact thrombus suction through a large-diameter catheter. This is a seductive first-line approach because it appears effective, safe, fast, and cost-effective. With recent publications of the Contact Aspiration Versus Stent Retriever for
Successful Revascularization (ASTER) and Aspiration thrombectomy versus stent retriever thrombectomy as first-line approach for large vessel occlusion (COMPASS) trials, ADAPT can now be considered a first-line option in the thrombectomy strategy. In case of aspiration failure, the endovascular technique can then be converted to a combined aspiration + stent retriever approach. These DACs must have specific characteristics such as navigability, torqueability, visibility, kink resistance, and aspiration capacity to obtain higher performance levels.

Sofia (soft torqueable catheter optimized for intracranial access; MicroVention, Tustin, California) is a DAC with a specific hybrid design. Its braid and coil construction combines different softness segments with a distal inner lumen of 0.055–0.070 inches, respectively, in 5F and 6F Plus versions. Despite previous publications, the safety and efficacy of this DAC in a large population with first-line Sofia use are yet to be reported.

Recanalization is a strong predictor of favorable outcome. Especially, the recently described first-pass effect (FPE), defined as a complete recanalization after 1 pass of mechanical thrombectomy, has been related to substantial improvement in clinical outcome compared with final good recanalization results after numerous passes. However, in the North American Solitaire Stent-Retriever Acute Stroke registry study, most patients were treated with a first-line stent retriever strategy. Data regarding the FPE under the ADAPT strategy are still underreported to date.

We present here the largest multicentric experience to date of the first-line ADAPT strategy using Sofia 6F Plus or 5F catheters. We aimed to study the clinical and angiographic effectiveness with specific attention to predictive factors of the first-pass effect.

**MATERIALS AND METHODS**

**Study Design and Population**

We performed a retrospective analysis of our prospectively maintained, multicentric Endovascular Treatment of Ischemic Stroke (ETIS) data base. ETIS is a prospective registry collecting data from patients benefiting from mechanical thrombectomy in 4 major French comprehensive stroke centers. Local ethics committees approved this study.

Consecutive patients from January 2013 to April 2018, presenting with acute ischemic stroke due to large-vessel occlusion strokes of the anterior or posterior circulation treated by mechanical thrombectomy using first-line ADAPT with a Sofia catheter were analyzed. We excluded patients treated first-line by another DAC, stent retrievers combined with distal aspiration, or stent retrievers alone. Extracranial occlusions were also excluded.

**Treatment Protocol**

The indication for treatment was left to the discretion of each operator according to local protocol. Intravenous thrombolyis treatment (IVT) was administered in association with mechanical thrombectomy in patients treated within 4.5 hours of stroke onset in the absence of contraindications. Endovascular treatment was performed with the patient under local anesthesia alone, conscious sedation, or general anesthesia depending on the patient’s condition and each contributing center’s anesthesia protocol.

For all selected cases, the operator’s decision was to perform distal aspiration through a Sofia catheter as the first intention. Sofia catheter choice was made according to operator’s discretion, local protocols, catheter availability, and occlusion topography to fit with the ADAPT strategy as a first-line treatment option. First, an 8F or 9F guide catheter was placed into the cervical internal carotid artery. Then, a Sofia 6F Plus or 5F was advanced over a microwire to the occlusion site with or without microcatheter support, depending on cervical and intracranial ICA tortuosity. The use of a balloon-guide catheter was left to the interventionist’s discretion. A 3-minute aspiration period, using either a dedicated pump or manual depression through a vacuum syringe, was applied before DAC removal. In the case of failure or partial efficacy, this maneuver could be repeated. In case of ADAPT failure or insufficient recanalization, the choice to convert to another endovascular technique (distal aspiration combined with stent retrievers or stent retrievers alone) was left to the operator’s discretion. Complementary endovascular treatments, such as cervical or intracranial angioplasty and/or stent placement, were performed depending on stroke etiology and severity and angiographically detected underlying lesions.

**Data Collection and Outcome Evaluation**

Age, sex, medical history, previous medication, stroke severity using the NIHSS score, stroke etiology, imaging technique, ASPECTS, IVT, and angiographic (arterial occlusion topography, degree of revascularization assessed by the modified TICI score) data were recorded.

Clinical outcome was assessed by the mRS 3 months after stroke. Favorable outcome was defined by an mRS ≤2. Angiographic reperfusion was rated using the TICI score. Successful revascularization was defined by mTICI ≥2b. Near-complete and excellent reperfusion was defined, respectively, by mTICI of 2c/3 and 3. The FPE was defined as an mTICI 3 after a single aspiration maneuver.

Safety criteria were also recorded, including procedural complications (dissection, embolism in a new territory, and intracranial arterial perforation), intracranial hemorrhage, and mortality. Procedural times were analyzed.

**Statistical Analysis**

Categoric variables were expressed as frequencies and percent-ages. Quantitative variables were expressed as means or medians (interquartile range, [IQR]) for non-normal distribution. The normality of distributions was assessed graphically and using the Shapiro-Wilk test.

Associations of baseline characteristics (patient and treatment characteristics) with outcomes (favorable outcome, successful and excellent reperfusion, FPE) were first investigated in center-adjusted analyses using generalized linear mixed models by including center as a random effect. To assess the independent predictors of each outcome, we entered all patient and treatment characteristics with a P < .20 in center-adjusted analyses into a backward-stepwise multivariable generalized linear mixed model using a removal criterion of P > .05. Before developing the multivariable prognostic models, we examined the log-linearity assumption for continuous characteristics using restricted cubic spline functions as well as the absence of collinearity between candidate predictors by calculating the variance inflation factors. To avoid case deletion in analyses due to missing data on baseline...
characteristics and outcomes, we imputed missing data by multiple imputations using a regression-switching approach (chained equations with $m/10$). The imputation procedure was performed under the missing at random assumption using all baseline characteristics and study outcomes with a predictive mean matching method for continuous variables and a multinomial or binary logistic regression model for categoric variables. Estimates obtained in the different imputed datasets were combined using the Rubin rules. Finally, we examined the performance of the final prognostic models in terms of discrimination by calculating the C-statistics in each imputed dataset and by reporting the median and range values.

Statistical testing was performed at the 2-tailed $\alpha$ level of .05. Data were analyzed using the SAS software package, Release 9.4 (SAS Institute, Cary, North Carolina).

RESULTS

Population and Participating Centers

From October 2013 to April 2018, we treated 2750 patients with an arterial large-vessel occlusion by mechanical thrombectomy at 4 comprehensive stroke centers. Of these, 296 (10.8%) who had undergone endovascular treatment with the Sofia aspiration catheter as a first-line approach were included in the present study (center A: 73 patients; B: 103 patients, C: 92 patients, D: 28 patients) (Figure).

The main patient and treatment characteristics are reported in Table 1. Overall, the mean age was 69.5 ± 13.8 years; 50.7% ($n = 150$) were men, and the median admission NIHSS score was 16 (IQR, 11–21). Intravenous tPA before endovascular treatment was administered in 48.3% ($n = 142$) of patients. The median time from symptom onset to arterial puncture was 242 minutes (IQR, 186–324 minutes). Most patients were treated with a 6F Sofia catheter ($n = 226, 76.3$%), and the remaining 70 (23.7%) were treated with a 5F catheter.

Effectiveness and Safety Outcomes

The main safety and effectiveness outcomes are summarized in Table 2. Thrombectomy was effective in 86.1% ($n = 255; 95\% CI, 81.7%–89.9\%) of patients (successful reperfusion, mTICI 2b–3) with a median number of passes of 2 (IQR, 1–3) and a median time of 40 minutes (IQR, 24–65 minutes) from groin puncture. Excellent reperfusion (mTICI 3) was achieved in 41.2% of patients ($n = 122; 95\% CI, 35.5%–47.1\%). The first-pass effect was achieved in 24.2% ($n = 71, 95\% CI, 19.4–29.6\%) of patients. Rescue therapy was required in 29.7% ($n = 88; 95\% CI, 24.6%–35.3\%) of patients. Procedural complications occurred in 9.5% ($n = 28; 95\% CI, 6.4%–13.5\%) of patients. These included 14 (4.7\%) new-territory embolisms, 4 (1.4\%) vessel perforations, 4 (1.4\%) extracranial carotid dissections, and 6 (2.0\%) vasospasms. Intracranial hemorrhage within 24 hours occurred in 44.6% ($n = 115; 95\% CI, 38.4%–50.9\%). Among these, there were 31 (12.0\%) parenchymal hematomas (PH-1 and PH-2) and 16 (6.2\%) symptomatic intracranial hemorrhages. At 90 days, 43% of patients ($n = 122; 95\% CI, 37.1%–48.9\%) were functionally independent (mRS 0–2); 50.5% ($n = 100; 95\% CI, 43.3%–57.7\%) had a 90-day favorable outcome. In this subgroup of patients, the mortality rate was 20.2% ($n = 40; 95\% CI, 14.8%–25.6\%).
CI, 5.6%–13.9%). These results are presented in Table 2.

### Predictors of 90-Day Favorable Outcome

Center-adjusted analyses of predictors of favorable outcome are detailed in On-line Table 3. In backward stepwise multivariable regression analysis, age, admission NIHSS score, hypertension, time intervals between onset to imaging and imaging to groin puncture, prestroke mRS ≥1, general anesthesia, and non-M1 MCA occlusion were associated with a decrease in the favorable outcome rate, whereas intravenous thrombolysis was associated with an increase (Table 3). This prognosis model had good discrimination (median C-statistic, 0.827; range, 0.816–0.838 across imputed datasets).

### Predictors of Successful and Complete Reperfusion

Center-adjusted analyses of predictors of successful and excellent reperfusion outcome are detailed in On-line Tables 4 and 5. A higher ASPECTS (OR per 1-point increase, 1.25; 95% CI, 1.08–1.45) and no current smoking (OR, 0.36; 95% CI, 0.18–0.72) were independently associated with successful reperfusion in backward stepwise multivariate regression analysis (Table 3). This prognosis model had good discrimination (median C-statistic, 0.735; range, 0.725–0.741 across imputed datasets).

For excellent reperfusion, we identified 5 independent predictors: older age, previous antiplatelet medications, lower blood glucose, site of occlusion (with a greater rate of excellent reperfusion for MCA M1 and vertebrobasilar occlusions), and Sofia 6F catheters (Table 3). This prognosis model also showed good discrimination (median C-statistic, 0.795; range, 0.793–0.795 across imputed datasets).

### Predictors of First-Pass Effect (mTICI 3 after 1 Pass)

Center-adjusted analyses of predictors of FPE are detailed in On-line Table 6. We identified 3 independent predictors: older age, site of occlusion (with a greater rate of excellent reperfusion after 1 pass for MCA M1 and vertebrobasilar occlusions), and intravenous thrombolysis (Table 3). This prognosis model also showed good discrimination (median C-statistic, 0.795; range, 0.793–0.795 across imputed datasets).

### DISCUSSION

Our study demonstrated a very high efficacy of first-line contact aspiration using the Sofia catheter with 86.1% successful reperfusion (mTICI 2b, 2c/3) and 43% favorable clinical outcome (mRS ≤1). The FPE rate was high (24.2%). Factors associated with higher recanalization rates were, notably, M1 and vertebrobasilar occlusions and the use of a 6F catheter.

### Clinical Outcomes

As previously described, outcome was significantly negatively influenced by age, stroke severity assessed by admission NIHSS score, prestroke mRS ≥1, general anesthesia, ICA terminus and tandem occlusions, and late treatment timeframe. Most interesting, IVT in combination with mechanical thrombectomy is associated with favorable outcome. These predictive factors have already been previously demonstrated with the use of either stent retrievers or the ADAPT technique.

The influence of general anesthesia on clinical outcomes is currently under debate. In our study, general anesthesia was not the first-line option for thrombectomy procedures among most participating centers. This anesthesia regimen was proposed for selected severe cases, thus likely explaining the association between general anesthesia and poorer outcomes in our work.

Despite several studies demonstrating the association between IVT and favorable outcome in cases of stroke treated with thrombectomy, IVT influence is still discussed. Future randomized trials will probably bring answers.

---

### Table 1: Baseline characteristics (n = 296)*

| Characteristics                          | No. | Values |
|------------------------------------------|-----|--------|
| Baseline demographics and medical history|     |        |
| Age (mean) (yr)                          | 296 | 69.5 ± 13.8 |
| Men                                      | 296 | 50 (50.7) |
| Hypertension                             | 288 | 54.9   |
| Diabetes                                 | 285 | 17.4   |
| Dyslipidemia                             | 284 | 32.7   |
| Current smoking                          | 272 | 25.7   |
| Previous stroke or TIA                   | 286 | 15.0   |
| Previous CAD                             | 285 | 17.5   |
| Antithrombotic medications               | 291 | 41.2   |
| Antiplaquelet                            | 291 | 23.7   |
| Anticoagulant                            | 291 | 11.7   |
| Current stroke event                     |     |        |
| Systolic BP (mean) (mm Hg)               | 245 | 148 ± 28 |
| Diastolic BP (mean) (mm Hg)              | 245 | 82 ± 19  |
| Blood glucose (median) (IQR) (mmol/L)    | 229 | 5.7–8.0 |
| Admission NIHSS score (median) (IQR)     | 290 | 11–21  |
| ASPECTS (median) (IQR)                   | 278 | 6–9    |
| Prestroke mRS ≥1                         | 291 | 22.0   |
| Site of occlusion                        |     |        |
| M1 MCA                                   | 296 | 41.9   |
| M2 MCA                                   | 40  | 13.5   |
| T-car                                    | 54  | 18.2   |

| Puncture to recanalization               | 287 | 25–65.5|
| Balloon-guide catheter                   | 296 | 7.8    |
| Mode of admission                        |     |        |
| Mothership                               | 295 | 41.0   |
| Drip and ship                            | 174 | 59.0   |
| Sofia catheter                           | 5F  | 23.7   |
|                                           | 296 | 226    |

*Values are expressed as No. (percentage) unless otherwise indicated.

Note: BP indicates blood pressure; CAD, coronary artery disease; T-car, occlusion of carotid terminus; Mothership, comprehensive stroke centers with on-site interventional neuroradiologic services; Drip and ship, medical treatment (including intravenous thrombolysis) in a hospital before being transferred to a comprehensive stroke centers for thrombectomy.

62.5%) and the procedural complication rate was 9.1% (n = 19; 95% CI, 5.6%–13.9%). These results are presented in Table 2.
In our study, rescue therapy using a stent retriever was required in 29.7%. This was a low rate, enhancing the high-efficacy level of aspiration first-pass alone in our experience. In the comparable current literature, rescue therapy after the ADAPT technique was needed in 31%–40%,6,16–22–24 Lower rescue therapy rates have been published with stent retrievers.25 However, this has to be questioned because the stent retriever approaches are often already associated with an intermediate catheter able to perform combined aspiration and thus can be seen as a maximalist strategy. Nevertheless, the probable need of a complementary rescue technique seems low.

Most interesting, we also emphasized a higher excellent reperfusion rate (mTICI 3) with a Sofia 6F than Sofia 5F. This strongly suggested a need for the largest diameter DAC possible to reach higher rates of reperfusion. This confirms previously published data.24,26,27

Our complication rate is low and in accordance with earlier reports. Moreover, the complication rate included benign events such as vasospasm. In the ASTER trial,6 the first-line contact aspiration group had a 16.2% complication rate, and the first-line stent retriever ASTER group had a 15.9% complication rate (non-significant difference). Blanc et al26 also reported a 13.3% rate.

**First-Pass Effect**

The FPE has recently been described as a strong prognostic factor of favorable outcome. Zaidat et al12 reported an FPE rate of 25.1% using stent retrievers exclusively. We report here an FPE rate of 24.2%. M1 and vertebrobasilar occlusions were significant predictors of FPE. These topographies appear to particularly fit with the first-line ADAPT strategy using the Sofia catheter. Predictors of FPE were also older age and intravenous thrombolysis. Zaidat et al found that older age was also associated with the FPE but only in univariate analysis. Most interesting, we found that IVT was 1 point in the NIHSS score at 24 hours. Favorable outcome is defined as a 90-day mRS ≤ 2.26

### Table 2: Efficacy and safety outcomes in the overall population and population without rescue therapy *(n = 296)*

| Outcomes | Overall | Values | 95% CI | Patients without Rescue Therapy | Values | 95% CI |
|----------|---------|--------|--------|---------------------------------|--------|--------|
| **Efficacy outcomes** | | | | | | |
| Successful reperfusion (mTICI 2b/3) | 255/296 (86.1) | 81.7–89.9 | 191/208 (91.8) | 87.2–95.2 |
| Near-complete reperfusion (mTICI 2c/3) | 157/296 (53.0) | 47.4–58.7 | 128/208 (61.5) | 54.6–68.2 |
| Excellent reperfusion (mTICI 3) | 122/296 (41.2) | 35.5–47.1 | 104/208 (50.0) | 43.0–57.0 |
| FPE (mTICI 3 after first pass) | 71/293 (24.2) | 19.4–29.6 | 71/208 (34.1) | 27.7–41.0 |
| Early neurologic improvement| 133/258 (51.6) | 45.4–57.7 | 109/184 (59.2) | 51.8–66.4 |
| Favorable outcome | 122/284 (43.0) | 37.1–48.9 | 100/198 (50.5) | 43.3–57.7 |
| Groin puncture-to-recanalization time (median) (IQR) | 40 (24–65) | 30.0 (21.0–50.0) | 46/208 (22.1) | 16.7–28.4 |
| No. of passes >2 | 117/293 (39.9) | 34.3–45.8 | 109/184 (59.2) | 51.8–66.4 |
| Rescue therapy | 88/296 (29.7) | 24.6–35.3 | | | |
| **Safety outcomes** | | | | | | |
| Procedural complications | 28/294 (9.5) | 6.4–13.5 | 19/208 (9.1) | 5.6–13.9 |
| Any ICH | 115/258 (44.6) | 38.4–50.9 | 79/177 (44.6) | 37.2–52.3 |
| PH | 31/258 (12.0) | 8.3–16.6 | 22/177 (12.4) | 8.0–18.2 |
| sICH | 16/258 (6.2) | 3.5–9.8 | 10/177 (5.6) | 2.7–10.1 |
| All-cause death (90-day) | 65/284 (22.9) | 18.1–28.2 | 40/198 (20.2) | 14.8–26.5 |

**Note:** ICH indicates intracranial hemorrhage; sICH, symptomatic intracranial hemorrhage.

* Values expressed as No./total No. (%) unless otherwise indicated.

**Early neurologic improvement is defined as NIHSS score 0–1 at 24 hours or a decrease of ≥4 points in the NIHSS score at 24 hours. Favorable outcome is defined as a 90-day mRS ≤ 2.

**Twenty-six missing data.

**Fourteen missing data.

**Angiographic Outcome**

We present here the largest population treated with first-line ADAPT using Sofia catheters. Our final rate of favorable mTICI (≥2b) appears similar to those previously published because authors noted favorable recanalization rates between 86.9% and 94.1% with the Sofia catheter.8–11 Gory et al16 reported 89% of mTICI 2b/3 in a meta-analysis of the overall literature dealing with ADAPT using various kinds of DACs. In comparison, reperfusion rates among ADAPT major trials were 92% and 85.4%, respectively, in the COMPASS and ASTER trials. Our results are consistent with these values.

Considering all types of mechanical thrombectomy approaches, these rates are among the best reported. For example, considering stent retrievers for most cases, the Highly Effective Reperfusion Evaluated in Multiple Endovascular Stroke (HERMES) trial meta-analysis revealed 71% successful reperfusion (mTICI 2b/3).1 Among the stent retriever subgroups of both the COMPASS and ASTER trials, final successful recanalization rates were, respectively, 89% and 83.1%. Of course, the maximalist strategy combining contact aspiration and stent retriever is currently presented as a promising technique. Previous studies reported a rate of 72.4% with the Aspiration-Retriever Technique for Stroke (ARTS) approach.17 New approaches such as Proximal Balloon Occlusion Together with Direct Thrombus Aspiration during Stent Retriever Thrombectomy (PROTECT+)18 and Stent Retriever Assisted Vacuum-Locked Extraction (SAVE) techniques19 seem to achieve very high recanalization levels. However, these findings can be balanced with the advantages of ADAPT as a first-line approach: ease of use, high effectiveness, and cost-effectiveness.

High-quality recanalization (mTICI 2c/3) is now considered a strong prognostic factor.20 We found that Sofia distal aspiration alone could achieve mTICI 2c/3 and mTICI 3 results in 53% and 41.2%. These rates are—as other indicators previously reported here—close to recently published data.5,21

In our study, rescue therapy using a stent retriever was required in 29.7%. This was a low rate, enhancing the high-efficacy level of aspiration first-pass alone in our experience. In the comparable current literature, rescue therapy after the ADAPT technique was needed in 31%–40%,6,16–22–24 Lower rescue therapy rates have been published with stent retrievers.25 However, this has to be questioned because the stent retriever approaches are often already associated with an intermediate catheter able to perform combined aspiration and thus can be seen as a maximalist strategy. Nevertheless, the probable need of a complementary rescue technique seems low.
use of a balloon-guide catheter was not significantly associated with FPE, but this could be explained by the rare use of balloon-guide catheters in our population. Recent publications reported very high rates of FPE.\textsuperscript{18,19} Once again, considering our results and literature data, the ADAPT strategy using Sofia catheters. Further trials comparing different catheters may be useful to appreciate the efficacy and safety differences between these devices.

### Limitations

One limitation of this study is its retrospective nature, which also limits the possibility of harmonizing endovascular procedures among different operators. This can constitute a bias in perioperative data analysis. Nevertheless, this point makes our results very likely to be representative of daily practice in different thrombectomy centers. The absence of core lab analysis might also constitute a limitation. Other potential limitations include differences in study-entry criteria and patient characteristics among the centers that may be a source of bias.

### CONCLUSIONS

The Sofia catheter is an efficient thrombectomy tool, with a good efficacy and safety profile. We demonstrated very high reperfusion rates (mTICI 2b/3 and FPE) with a first-line thrombectomy strategy using Sofia catheters. Further trials comparing different catheters may be useful to appreciate the efficacy and safety differences between these devices.
