Superfluid density and specific heat within self-consistent scheme for two-band superconductor

V. G. Kogan, C. Martin, and R. Prozorov
Ames Laboratory and Department of Physics & Astronomy, Iowa State University, Ames, IA 50011
(Dated: 30 April 2009)

The two gaps in a two-band clean s-wave superconductor are evaluated self-consistently within the quasiclassical Eilenberger weak-coupling formalism with two in-band and one inter-band pairing potentials. Superfluid density, free energy and specific heat are given in the form amenable for fitting the experimental data. Well-known two-band MgB$_2$ and V$_3$Si superconductors are used to test the developed approach. The pairing potentials obtained from the fit of the superfluid density data in MgB$_2$ crystal were used to calculate temperature-dependent specific heat, $C(T)$. The calculated $C(T)$ compares very well with the experimental data. Advantages and validity of this, what we call the “γ-model”, are discussed and compared with the commonly used empirical (and not self-consistent) “α-model”. Correlation between the sign of the inter-band coupling and the signs of the two order parameters is discussed. Suppression of the critical temperature by the inter-band scattering is evaluated and shown to be severe for the inter-band repulsion as compared to the attraction. The data on a strong $T_c$ suppression in MgB$_2$ crystals by impurities suggest that the order parameters on two effective bands of this material may have opposite signs, i.e., may have the $s_{±}$ structure similar to the current proposals in iron-based pnictide superconductors.

I. INTRODUCTION

Nearly all superconductors discovered recently and some well-studied compounds (e.g., Nb$_2$Se and V$_3$Si) are multiband materials with complex Fermi surfaces and anisotropic order parameters. Measuring temperature dependences of the London penetration depth $\lambda(T)$, often converted to the superfluid density $\rho(T) = \lambda(0)^2/\lambda(T)^2$, and of the electronic specific heat $C(T)$, are among primary tests directly linked to pairing mechanisms of new superconductors. Still, the methods employed to interpret the data are often empiric with simplicity as a main justification.

The most popular among practitioners “α-model” takes a shortcut by assigning the BCS temperature dependence to the two gaps $\Delta_{1,2}$ with which to fit data on the specific heat and the superfluid density $\rho = x\rho_1 + (1-x)\rho_2$. Here, $\rho_{1,2}$ are evaluated with $\Delta_{1,2} = (\alpha_{1,2}/1.76)\Delta_{BCS}(T)$ and $x$ takes account the relative band contributions. Although the α-model had played an important and timely role in providing convincing evidence for the two-gap superconductivity in MgB$_2$, it is intrinsically inconsistent in the most important task of this procedure, namely, in describing properly the temperature dependencies of $\rho(T)$ and $C(T)$. In fact, one cannot a priori assume temperature dependencies for the gaps in the presence of however weak interband coupling imposing the same $T_c$ for two bands. In unlikely situation of zero interband coupling, two gaps would have single-gap BCS-like $T−$ dependencies, but will have two different transition temperatures, see Fig. 1.

The full-blown microscopic approach based on the Eliashberg theory, on the other hand, is quite involved and difficult for the data analysis. Hence, the need for a relatively simple but justifiable, self-consistent and effective scheme experimentalists could employ. The weak-coupling model is such a scheme. Over the years, the weak-coupling theory had proven to describe well multitude of superconducting phenomena. Similar to the weak coupling is the “renormalized BCS” model of Ref. 6 that incorporates the Eliashberg corrections in the effective coupling constants in a manner described below. We will call our approach a “weak-coupling two-band scheme” and clarify in the text below that applicability of the model for the analysis of the superfluid density and specific heat data is broader than the traditional weak coupling.

The s-wave weak-coupling multigap model has been proposed at the dawn of superconductivity theory by Moskalenko and Suhl, Matthias, and Walker when numerical tools were still in infancy. In this work we basically follow these seminal publications to develop a self-consistent procedure for the penetration depth data analysis. Our scheme allows one to connect between two independent data sets, the superfluid density and the specific heat, thus providing a reliability check upon values of the coupling constants extracted from fitting the data. We also discuss the suppression of the critical temperature $T_c$ by non-magnetic impurities and suggest that the data on this suppression for MgB$_2$ are consistent with a weak repulsive interband interaction that corresponds to opposite signs of the order parameter on two bands, i.e., to $\pm s$ structure of the order parameter.

To test our formal scheme, the data for two known s-wave two-gap superconductors, MgB$_2$ and V$_3$Si, were used. The specific heat data were taken from the Ref. 9. The magnetic penetration depth, $\lambda(T)$, was measured by using a self-oscillating tunnel-diode resonator (TDR) with resonant frequency $f_0 \approx 14$ MHz. The measured quantity is the shift of this frequency, $f(T) − f_0 =$...
with the geometric factor defined by volumes of the coil, \( V_c \), and of the sample, \( V_s \), and by the demagnetization factor \( N \). \( G \) is measured directly by pulling the sample out of the coil at the lowest temperature.\(^3\) For the susceptibility we use\( 4\pi \chi(T) = \lambda(T) / w \tanh[w / \lambda(T)] - 1 \).\(^10\)

### II. EILENBERGER TWO-BAND SCHEME

Perhaps, the simplest formally weak-coupling approach is based on the Eilenberger quasiclassical formulation of the superconductivity valid for general anisotropic order parameters and Fermi surfaces.\(^11\) Eilenberger functions \( f, g \) for clean materials in equilibrium obey the system:

\[
\begin{align*}
0 &= 2\Delta g / \hbar - 2\omega f, \\
g^2 &= 1 - f^2, \\
\Delta(k) &= 2\pi TN(0) \sum_{\omega > 0} \langle V(k, k') f(k', \omega) \rangle_{k'}. 
\end{align*}
\]

Here, \( k \) is the Fermi momentum; \( \Delta \) is the gap function which may depend on the position \( k \) at the Fermi surface in cases other than the isotropic s-wave. Further, \( N(0) \) is the total density of states at the Fermi level per one spin; the Matsubara frequencies are defined by \( \hbar \omega = \pi T (2n + 1) \) with an integer \( n \), and \( \omega_D \) is the Debye frequency; \( \langle \ldots \rangle \) stands for averages over the Fermi surface. As a weak coupling theory the Eilenberger scheme deals with the effective electron-electron coupling \( V \) responsible for superconductivity; properties of intermediate bosons (phonons or other possible mediators) enter via properly renormalized \( V \).

Consider a model material with the gap given by

\[
\Delta(k) = \Delta_{1,2}, \quad k \in F_{1,2},
\]

where \( F_1, F_2 \) are two sheets of the Fermi surface. The gaps are constant at each band. Denoting the densities of states on the two parts as \( N_{1,2} \), we have for a quantity \( X \) constant at each Fermi sheet:

\[
\langle X \rangle = \langle X_1 N_1 + X_2 N_2 \rangle / N(0) = n_1 X_1 + n_2 X_2,
\]

where \( n_{1,2} = N_{1,2} / N(0) \); clearly, \( n_1 + n_2 = 1 \).

Equations (1) and (2) are easily solved. Within the two-band model we have:

\[
\begin{align*}
f_\nu &= \Delta_\nu / \beta_\nu, & g_\nu &= \hbar \omega / \beta_\nu, & \beta_\nu^2 = \Delta_\nu^2 + \hbar^2 \omega^2, 
\end{align*}
\]

where the band index \( \nu = 1, 2 \). The self-consistency equation (3) takes the form:

\[
\Delta_\nu = 2\pi T \sum_{\mu=1,2} n_\nu \lambda_{\nu\mu} f_\mu = \sum_{\mu} n_\mu \lambda_{\nu\mu} \Delta_\mu \sum_{\omega} \omega^2 / \beta_\mu^2, \quad (7)
\]

where \( \lambda_{\nu\mu} = N(0) V(\nu, \mu) \) are dimensionless effective interaction constants.

A remark is here in order on applicability of Eq. (7) central for our approach. Starting with the general Eliashberg formalism, Nicol and Carbotte derived a “renormalized BCS” self-consistency equation.\(^6\)

\[
\Delta_\nu = \frac{2\pi T}{Z_\nu} \sum_{\mu, \omega} \lambda_{\nu\mu}^{ep} - \mu_{\nu\mu}^{ep} f_\mu, \quad (8)
\]

where \( \lambda_{\nu\mu}^{ep} \) is the coupling due to electron-phonon interaction, \( \mu_{\nu\mu}^{ep} \) describes the Coulomb interaction, and \( Z_\nu = 1 + \sum_\nu \lambda_{\nu\mu}^{ep} \) is the strong coupling renormalization. Replacing \( (\lambda_{\nu\mu}^{ep} - \mu_{\nu\mu}^{ep}) / Z_\nu \) \( n_\nu \lambda_{\nu\mu} \) we obtain our Eq. (7). One should have this in mind while interpreting the constants \( \lambda_{\nu\mu} \) which can be obtained from fitting the data to our “renormalized weak-coupling” model.

Note that the notation commonly used in literature for \( \lambda_{\nu\mu}^{(it)} \) differs from ours: \( \lambda_{\nu\mu}^{(it)} = n_\nu \lambda_{\nu\mu} \). We find our notation convenient since, being proportional to the coupling potential, our coupling matrix is symmetric: \( \lambda_{\nu\mu} = \lambda_{\mu\nu} \).

It is worth stressing that for a given coupling matrix \( \lambda_{\mu\nu} \), relative densities of states \( n_\nu \), and the energy scale \( \hbar \omega_D \), Eq. (7) determines both \( T_c \) and \( \Delta_{1,2}(T) \).

#### A. Critical temperature \( T_c \)

As \( T \to T_c \), \( \Delta_{1,2} \to 0 \), and \( \beta \to \hbar \omega \). The sum over \( \omega \) in Eq. (7) is readily evaluated:

\[
S = \sum_\omega \frac{2\pi T}{\hbar \omega} = \ln \frac{2\hbar \omega_D}{T_c \pi e^{-\gamma}} = \ln \frac{2\hbar \omega_D}{1.76 T_c}, \quad (9)
\]

\( \gamma = 0.577 \) is the Euler constant. This relation can also be written as:

\[
1.76 T_c = 2\hbar \omega_D e^{-S}. \quad (10)
\]

The system (7) is linear and homogeneous:

\[
\begin{align*}
\Delta_1 &= S(n_1 \lambda_{11} \Delta_1 + n_2 \lambda_{12} \Delta_2), \\
\Delta_2 &= S(n_1 \lambda_{12} \Delta_1 + n_2 \lambda_{22} \Delta_2). 
\end{align*}
\]

(11)

It has nontrivial solutions \( \Delta_{1,2} \) if its determinant is zero:

\[
S^2 n_1 n_2 \eta - S(n_1 \lambda_{11} + n_2 \lambda_{22}) + 1 = 0, \quad \eta = \lambda_{11} \lambda_{22} - \lambda_{12}^2. \quad (12)
\]

The roots of this equation are:

\[
S = n_1 \lambda_{11} + n_2 \lambda_{22} \pm \sqrt{((n_1 \lambda_{11} + n_2 \lambda_{22})^2 - 4n_1 n_2 \eta)} \]

\[
= \frac{n_1 \lambda_{11} + n_2 \lambda_{22} \pm \sqrt{(n_1 \lambda_{11} - n_2 \lambda_{22})^2 + 4n_1 n_2 \lambda_{12}^2}}{2n_1 n_2 \eta}. \quad (13)
\]
Since $T_c \ll \hbar \omega_D$, Eq. (10) shows that only positive $S$ are admissible. The second form (13) shows that both roots are real; their product is $S_1 S_2 = 1/n_1 n_2 \eta$. Choosing a proper root, one should consider various possibilities. If $\eta > 0$ (that implies both $\lambda_{11}$ and $\lambda_{22}$ are of the same sign), Eq. (13) shows that both roots are positive, and one should choose the smallest (to have maximum $T_c$). If $\eta < 0$ ($\lambda_{12}^2 > \lambda_{11} \lambda_{22}$ that can happen (i) for a sufficiently strong interband coupling for both $\lambda_{11}$ and $\lambda_{22}$ positive or (ii) if one of $\lambda_{11}, \lambda_{22}$ is repulsive), one should take the square root with minus. It is of interest to note that even for $\lambda_{11} = \lambda_{22} = 0$, the interband coupling of either sign may lead to superconductivity. In fact, $S = 1/\sqrt{n_1 n_2} |\lambda_{12}|$ for a dominant interband interaction $|\lambda_{12}| \gg |n_1 \lambda_{11} + n_2 \lambda_{22}|$. However exotic, this possibility should not be ignored. This situation has been considered time ago by Geilikman\textsuperscript{12} who found that interband Coulomb repulsion could lead to superconductivity; recently this possibility has been considered by Mazin and Schmalian in a discussion of superconductivity in the iron-pnictides.\textsuperscript{13} If $\eta = 0$, Eq. (12) yields $S = 1/(n_1 \lambda_{11} + n_2 \lambda_{22})$. Finally, if the interband coupling is exactly zero, a quite unlikely situation, the second form of $S$ in Eq. (13) gives two roots $1/n_1 \lambda_{11}$ and $1/n_2 \lambda_{22}$. The smallest one gives $T_c$, whereas the other corresponds to the temperature at which the small gap turns zero. This situation is depicted in Fig. 1.

We conclude this incomplete list of possibilities by noting that within this model, interband coupling enters only as $\lambda$, affecting that within this model, interband coupling enters exactly as does the repulsion. This is no longer true in the presence of interband scattering, the question discussed below. Denoting the properly chosen root as $S = 1/\tilde{\lambda}$ we have:

$$1.76 T_c = 2 \hbar \omega_D \exp(-1/\tilde{\lambda}).$$ \hspace{1cm} (14)

One easily checks that for all $\lambda$’s equal this yields the standard BCS result. Among various possibilities we mention here the case $\eta = \lambda_{11} \lambda_{22} - \lambda_{12}^2 = 0$ for which

$$\tilde{\lambda} = n_1 \lambda_{11} + n_2 \lambda_{22} = \langle \lambda \rangle.$$

This case corresponds to a popular model with factorizable coupling potential $V(k, k') = V_0 \Omega(k) \Omega(k')$.\textsuperscript{14} This potential is amenable for analytic work, but it reduces severely the richness of the two-band scheme.

Since the determinant of the system (11) is zero, the two equations are equivalent and give near $T_c$:

$$\frac{\Delta_2}{\Delta_1} = \frac{\tilde{\lambda} - n_1 \lambda_{11}}{n_2 \lambda_{12}}.$$ \hspace{1cm} (16)

When the right-hand side is negative, $\Delta$’s are of opposite signs. Within the one-band BCS, the sign of $\Delta$ is a matter of convenience; in fact for one band the self-consistency equation determines only $|\Delta|$. For two bands, $\Delta_1$ and $\Delta_2$ may have opposite signs. If the $\Delta$ values are $+D_1$ and $-D_2$, Eq. (7) shows that $-D_1$ and $+D_2$ is a solution too. One should be aware of this multiplicity of solutions when solving the system (7) numerically. The problem is even worse because $\Delta_1 = \Delta_2 = 0$ is always a solution.

**B. Order parameter**

Turning to evaluation of $\Delta_\nu(T)$, we note that the sum in Eq. (7) is logarithmically divergent. To deal with this difficulty, we employ Eilenberger’s idea of replacing $\hbar \omega_D$ with the measurable $T_c$. These are related by Eq. (14).
which can be written as
\[ \frac{1}{\lambda} = \ln \frac{T}{T_c} + \sum_{\omega} \frac{2 \pi T}{\hbar \omega}. \] (17)

Now add and subtract the last sum from one in Eq. (7):
\[ \Delta_\nu = \sum_\mu n_\mu \lambda_{\nu \mu} \Delta_\mu \left[ \sum_\omega \left( \frac{2 \pi T}{\beta_\mu} - \frac{2 \pi T}{\hbar \omega} \right) + \sum_\omega \frac{2 \pi T}{\hbar \omega} \right] \]
\[ = \sum_\mu n_\mu \lambda_{\nu \mu} \Delta_\mu \left[ \sum_\omega \left( \frac{2 \pi T}{\beta_\mu} - \frac{2 \pi T}{\hbar \omega} \right) + \frac{1}{\lambda} - \ln \frac{T}{T_c} \right] \] (18)

The last sum over \( \omega \) is fast-converging and one can replace \( \omega_D \) with \( \infty \). Numerically, the upper limit of summation over \( n \) can be set as a few hundreds that suffices even for low temperatures. Introducing dimensionless quantities
\[ \delta_\nu = \frac{\Delta_\nu}{2 \pi T} = \frac{\Delta_\nu}{T_c} \frac{1}{2 \pi t}, \] (19)

with \( t = T/T_c \), we rewrite Eq. (18):
\[ \delta_\nu = \sum_{\mu=1,2} n_\mu \lambda_{\nu \mu} \delta_\mu \left( \frac{1}{\lambda} + \ln \frac{T_c}{T} - A_\mu \right), \]
\[ A_\mu = \sum_{n=0}^{\infty} \left( \frac{1}{n+1/2} - \frac{1}{\sqrt{\delta_{\mu}^2 + (n+1/2)^2}} \right). \] (20)

For given coupling constants \( \lambda_{\nu \mu} \) and densities of states \( n_\nu \), this system of two equations can be solved numerically for \( \delta_\nu \) and therefore provide the gaps \( \Delta_\nu = 2 \pi T \delta_\nu(t) \). Two examples of these solutions with the sets of parameters differing only in \( \lambda_{12} \) are given in insets to Figs. 1 and 2. We observe that even a small interband coupling changes drastically the behavior of the small gap.

### C. Superfluid density

Having formulated the way to evaluate \( \Delta(T) \), we turn to the London penetration depth given for general anisotropies of the Fermi surface and of \( \Delta \) by (see e.g., Ref. 15):
\[ (\lambda_L^2)_{ik}^{-1} = \frac{16 \pi^2 e^2 N(0) T}{c^2} \sum_\omega \langle \frac{\Delta_\nu^2 v_\nu v_k}{\beta_\nu^3} \rangle. \] (21)

where \( v_\nu \) is the Fermi velocity. We consider here only the case of currents in the \( ab \) plane of uniaxial or cubic materials with two separate Fermi surface sheets, for which a simple algebra gives for the superfluid density \( \rho = \lambda_{ab}^2(0)/\lambda_{ab}^2(T) \):
\[ \rho = \gamma \rho_1 + (1 - \gamma) \rho_2, \]
\[ \rho_\nu = \delta_\nu^2 \sum_{n=0}^{\infty} [\delta_\nu^2 + (n + 1/2)^2]^{-3/2}, \]
\[ \gamma = \frac{n_1 v_1^2}{n_1 v_1^2 + n_2 v_2^2}. \] (22)

where \( v_\nu^2 \) are averages over corresponding band of the in-plane Fermi velocities. The formal similarity of the first line here to the widely used \( \alpha \)-model (with an \( x \) in place of out \( \gamma \)) prompts to name our scheme the “\( \gamma \)-model” (we do not renormalize the gaps, so no analog of \( \alpha \) exists in our scheme. We note, however, that our \( \gamma \) that determines partial contributions from each band is not just a partial density of states \( n_1 \) of the \( \alpha \)-model, instead it involves the band’s Fermi velocities.

We now apply the approach developed to fit the data for the superfluid density of MgB\(_2\) crystals acquired by using the TDR technique described above. Figure 3 shows the result of the fitting with three free parameters: \( \lambda_{11}, \lambda_{22}, \) and \( \lambda_{12} \). The partial density of states and the parameter \( \gamma \) were taken from the literature: the two-band mapping of the four-band MgB\(_2\) gives \( n_1 = 0.44 \) and the Fermi velocities \( \langle v_{ab}^2 \rangle_1 = 3.3 \) and \( \langle v_{ab}^2 \rangle_2 = 2.3 \times 10^{15} \text{cm}^2/\text{s}^2 \). This fit requires solving two coupled nonlinear equations, Eqs. (20). We used Matlab with the Optimization toolbox and utilized a nonlinear solver using direct Nelder-Mead simplex search method. The result is shown in Fig. 3 with the best fit parameters listed in the caption. We show below that the same set of parameters used to calculate the free energy and the specific heat reproduces the data on \( C(T) \) remarkably well.

Our numerical experimentation shows that if, in addition to coupling constants, the partial densities of states and the Fermi velocities are unknown, the fitting procedure becomes unstable and good fits can be found for various combinations of the coupling constants. In the case of MgB\(_2\) these quantities are known and our fitting is quite certain.

For \( \text{V}_4\text{Si} \) we do not have detailed information regarding the band structure, partial densities of states, and Fermi velocities on separate sheets of the Fermi surface of this material. Hence, we took all those as free parameters in the fitting procedure. The conclusions thus are less reliable for this material than for MgB\(_2\): being mapped onto a two-band model, \( \text{V}_4\text{Si} \) comes out to have two nearly decoupled bands with an extremely weak interband coupling (still sufficient to give a single \( T_c \)). The results and the best-fit parameters are given in the caption to Fig. 4. Note that the long linear tail in \( \rho(t) \) as \( T \) approaches \( T_c \) is a direct manifestation of a very small gap, in this case \( \Delta_1 \), in this temperature domain.
III. FREE ENERGY AND SPECIFIC HEAT

By fitting the data for $\rho(t)$, we can extract the coupling constants $\lambda_{\nu\mu}$ along with $\Delta_\nu(T)$. This allows one to determine all thermodynamic properties of the material in question, of which we consider here the specific heat $C(T)$ and its jump at $T_c$. To this end, one starts with the Eilenberger expression for the energy difference:

$$
\frac{F_n - F_s}{N(0)} = 2\pi T \sum_{\nu,\omega} n_\nu \frac{(\beta_\nu - \hbar\omega)^2}{\beta_\nu}.
$$

Near $T_c$, one obtains:

$$
\frac{F_n - F_s}{N(0)} = \frac{7\zeta(3)}{16\pi^2 T_c} \sum_\nu n_\nu \Delta_\nu^4
= \frac{7\zeta(3)}{2\pi^2 T_c} \sum_\nu n_\nu \delta_\nu^4.
$$

Following Ref. 7, one can look for solutions $\delta_\nu(t)$ of Eq. (20) near $T_c$ as an expansion:

$$
\delta_\nu = a_\nu \tau^{1/2} + b_\nu \tau^{3/2}, \quad \tau = 1 - t.
$$

We substitute this in Eq. (20) and compare terms of different powers of $\tau$; the quantity $A_\nu = 7\zeta(3)a_\nu^2\tau^2 + O(\tau^3)$. In the lowest order we obtain the system of linear homogeneous equations for $a_1, a_2$ that coincides with the system (11). The same arguments that led to Eq. (16) provide

$$
a_2 = a_1 G = a_1 \frac{\hat{\lambda} - n_1 \lambda_{11}}{n_2 \lambda_{12}}.
$$

The conditions for existence of non-trivial solutions for $b_\nu$ in the next order provide the second relation for $a_\nu$. We omit a cumbersome algebra and give the result:

$$
a_\nu^2 = \frac{2}{7\zeta(3)} \frac{\hat{\lambda}^2 - n_1 n_2 \eta}{\lambda(n_1 \lambda_{11} + n_2 \lambda_{12} G^3) - n_1 n_2 \eta}.
$$

We now obtain the energy near $T_c$,

$$
F_n - F_s = 7\zeta(3) N(0) \pi^2 T_c^4 \sum_\nu n_\nu a_\nu^4 \tau^2 = B \tau^2,
$$

and the specific heat:

$$
C_s - C_n = \frac{2 B}{T_c} = 14\zeta(3) \pi^2 N(0) T_c \sum_\nu n_\nu a_\nu^4.
$$

The relative jump at $T_c$ is:

$$
\frac{\Delta C}{C_n} = \frac{12}{7\zeta(3)} \frac{(n_1 + n_2 G^4)}{(n_1 \lambda_{11} + n_2 \lambda_{12} G^3 - n_1 n_2 \eta)^2}.
$$

If all coupling constants are the same, $\eta = 0$, $G = 1$, and $\Delta C/C_n = 12/7\zeta(3) = 1.43$, as is should be. We note that the sign of the interband coupling $\lambda_{12}$ has no effect on the jump $\Delta C$ since in Eq. (30) $\lambda_{12} G$ is insensitive to this sign.

It is easy to study numerically the jump dependence on the three coupling parameters. As an example...
Now we can test our theory by employing the parameters obtained from the fit to the data on superfluid density as shown in Fig. 3 and calculate the free energy and the specific heat. The result is shown in Fig. 6. The dashed line shows a single-gap weak-coupling BCS results and the solid line is the result of our calculations. Note that this is not a fit, but a calculation with parameters determined in independent measurement. The data shown by circles are taken from Ref. 9. Since this is NOT a fit, the agreement with the general behavior of $C(T)$ and, in particular, with value of the jump at $T_c$ is remarkable.

IV. $T_c$ SUPPRESSION BY NON-MAGNETIC IMPURITIES

The intraband scattering does not affect $T_c$, so that we focus on the effect of interband scattering with an average scattering time $\tau$. Since $g = 1$ at $T_c$, the Eilenberger equations for $f_{i,2}$ in two bands read:\textsuperscript{18}

$$
0 = 2\Delta_1 - 2\omega f_1 + \nu_2(f_2 - f_1)/\tau, \\
0 = 2\Delta_1 - 2\omega f_1 + \nu_2(f_2 - f_1)/\tau,
$$

($\hbar = 1$). This system yields:

$$
\begin{align*}
 f_1 &= \frac{\Delta_1(\omega + n_1/2\tau) + \Delta_2 n_2/2\tau}{\omega\omega'}, \\
 f_2 &= \frac{\Delta_2(\omega + n_2/2\tau) + \Delta_1 n_1/2\tau}{\omega\omega'},
\end{align*}
$$

where $\omega' = \omega + 1/2\tau$. The self-consistency equation,

$$
\Delta_\nu = \sum_{\mu,\omega} n_\mu \lambda_{\nu\mu} f_\mu , \tag{35}
$$

again reduces to a system of linear and homogeneous equations for $\Delta_{1,2}$, the determinant of which must be zero. Omitting the algebra, we give the result:

$$
\begin{align*}
 P^2 n_1 n_2 &- P(n_1 \lambda_{11} + n_2 \lambda_{22} - n_1 n_2 \eta Q) + 1 - Q(n_1 \eta_1 + n_2 \eta_2) = 0, \\
 \eta_1 &= n_1 \lambda_{11} + n_2 \lambda_{12}, \quad \eta_2 = n_2 \lambda_{22} + n_1 \lambda_{12}, \tag{36}
\end{align*}
$$

$\eta$ is defined in Eq. (12). The quantities $P, Q$ are given by:

$$
\begin{align*}
 P &= \sum_\omega \frac{2\pi T_c}{\omega} \ln \frac{\omega D}{2\pi T_c} - \psi\left(\frac{1}{2} + \frac{\rho_0}{2\tau}\right), \tag{38}
 Q &= \frac{1}{2\tau} \sum_\omega \frac{2\pi T}{\omega\omega'} = \psi\left(\frac{1}{2} + \frac{\rho_0}{2\tau}\right) - \psi\left(\frac{1}{2}\right), \tag{39}
\end{align*}
$$

where $t = T_c/T_c^0$ with $T_c^0$ being the critical temperature of the clean material given in Eq. (14). The scattering parameter

$$
\rho_0 = \frac{1}{2\pi T_c^0 \tau}. \tag{40}
$$
One can easily rearrange \( P \) to the form:

\[
P = \frac{1}{\lambda} - \ln t - Q.
\]

(41)

Next, one solves the quadratic Eq. (36) for \( P \) and chooses the smaller of two roots (with the minus sign in front of the square root). Denoting this root as \( P_t(\lambda, \rho_0, t) \) where \( \lambda \) stands for the set of all coupling constants and of partial densities of states, we obtain an implicit equation for \( t(\rho) \) that can be solved numerically:

\[
\frac{1}{\lambda} - \ln t - Q(t, \rho) = P_t(\lambda, \rho, t).
\]

(42)

For the case \( \eta = 0 \), the only root of Eq. (36) is

\[
P_t = \frac{1 - Q(n_1\eta_1 + n_2\eta_2)}{n_1\lambda_{11} + n_2\lambda_{22}}.
\]

(43)

Since in this particular case \( \lambda = n_1\lambda_{11} + n_2\lambda_{22} \), we obtain:

\[
-\ln t = Q\left(1 - \frac{n_1^2\lambda_{11} + 2n_1n_2\lambda_{12} + n_2^2\lambda_{22}}{n_1\lambda_{11} + n_2\lambda_{22}}\right).
\]

(44)

One can verify that this coincides with the suppression formula obtained within the model with factorizable coupling potential, see Ref. 15 or a more general work by Openov. With the parentheses on the right-hand side equal to 1, this is just the Abrikosov-Gor’kov result for the \( T_c \) suppression by a pair-braker with the scattering parameter \( \rho_0 \). Thus, only if \( n_1^2\lambda_{11} + 2n_1n_2\lambda_{12} + n_2^2\lambda_{22} \leq 0 \), or

\[
\lambda_{12} \leq -\frac{n_2^2\lambda_{11} + n_1^2\lambda_{22}}{2n_1n_2},
\]

(45)

\( T_c \) drops to zero at a finite \( \tau \). Otherwise \( T_c(\rho_0) \) is a decreasing function at all \( \rho_0 \).

One can show numerically that these features of the \( T_c \) suppression are qualitatively the same for a general two-band case: unlike formulas of preceding sections describing clean materials, the sign of the interband coupling \( \lambda_{12} \) does affect the \( T_c \) suppression. One can verify that the interband scattering causes faster decrease of \( T_c \) if the interband coupling is repulsive, \( \lambda_{12} < 0 \).

To illustrate this point we calculate suppression of \( T_c \) with the coupling parameters \( \lambda_{11} = 0.3, \lambda_{22} = 0.2 \), and with three different values of \( \lambda_{12} \) shown in Figure 7. Whereas with positive \( \lambda_{12} \) the suppression is weak and similar to the case of materials having one anisotropic gap, the suppression for \( \lambda_{12} < 0 \) is much stronger. This finding can be checked experimentally and, in fact, the published data on unusually fast suppression of \( T_c \) with carbon, aluminum, or lithium doping imply that MgB₂ might have repulsive interband coupling. Otherwise, it is hard to reconcile the \( T_c \) suppression by a factor of 4 by 15% of C substitution. If one interprets this effect as caused by impurities scattering, Eq. (42) with \( \lambda_{12} = +0.06 \) provides \( \rho_0 \sim 10^3 \) needed for such a suppression. This value of the scattering parameter corresponds to unrealistically short mean-free path \( \ell \sim 1 \AA \) less. Changing the sign of \( \lambda_{12} \) to negative (i.e. taking the interband coupling as repulsive), results in \( \rho_0 \approx 0.37 \) and a reasonable estimate of \( \ell \approx 400 \AA \). The negative interband coupling would imply opposite signs of the order parameter on the two effective bands of MgB₂, i.e. \( \pm \)s order parameter, a proposition calling for more studies.

V. SUMMARY

We have presented a two-band weak-coupling \( \gamma \)-model that takes into account self-consistently all relevant coupling constants to evaluate temperature dependencies of the two gaps, of the superfluid density, and of the specific heat in clean s-wave materials. The interband coupling is shown to have a strong effect on these dependencies irrespective of the sign of this coupling. In particular, if the interband coupling is negative (repulsive) it may cause the two order parameters to have opposite signs, i.e. the order parameter may have the \( \pm \)s structure. In this case, the \( T_c \) suppression by interband scattering should be very strong, the feature that can be utilized as a signature of the \( \pm \)s order parameter. We speculate that a strong \( T_c \) suppression by various dopants in MgB₂ may signal such a possibility. All these features make the model advantageous to the empiric and not self-consistent \( \alpha \)-model commonly employed to interpret the data on penetration depth and specific heat of two-gap materials.
