Recent evidence demonstrated that dopamine within the nucleus accumbens mediates consolidation of both associative and nonassociative memories. However, the specific contribution of the nucleus accumbens subregions, core and shell, and of D1 and D2 receptors subtypes has not been yet clarified. The aim of this study was, therefore, to directly compare the effect of D1 and D2 dopamine receptor blockade within the core and the shell subregions of the nucleus accumbens on memory consolidation. Using the one-trial inhibitory avoidance task in CD1 mice, we demonstrated that SCH 23390 (vehicle, 12.5, 25, 50 ng/side) administration within the core, but not the shell, impaired step-through latency 24 h after the administration if injected immediately, but not 20 min post-training. Interestingly, sulpiride (vehicle, 25, 50 ng/side) injection in both the core and the shell of the accumbens affected step-through latency 24 h later; also, in this case the impairment was time dependent. These data provide the most complete and direct demonstration to date that early consolidation of aversive memory requires D2 receptor activation in both nucleus accumbens subregions, and D1 activation selectively in the nucleus accumbens core.

Dopamine (DA) within the nucleus accumbens (Nac) was initially regarded as crucial in mediating motivational properties of rewards and drugs of abuse (Di Chiara and Bassareo 2007). Recently, however, increasing attention is being focused on the learning and memory functions of DA within the Nac (Ploeger et al. 1994; Setlow and McGaugh 1998; Di Ciano et al. 2001; Di Ciano and Everitt 2004; Mele et al. 2004; Dalley et al. 2005; Ferretti et al. 2005; Cheng and Feenstra 2006; Brossert et al. 2007; Cheer et al. 2007; Kuo et al. 2007).

Recent experimental evidence, by means of post-training Nac focal administrations, demonstrated that DA is necessary for memory consolidation in a variety of behavioral tasks, such as the hidden version of the water maze, the object-place association, and the one-trial inhibitory avoidance tasks (Setlow and McGaugh 1998; Di Ciano et al. 2001; Mele et al. 2004; Dalley et al. 2005; Ferretti et al. 2005; Laurencin et al. 2006; Brossert et al. 2007; Cheer et al. 2007). It must be said, however, that DA can act on different DA receptor subtypes, D1- and D2-like; D1- and D2-like receptors are thought to have opposite effects on different forms of neuronal plasticity, and consequently on learning and memory, due to their opposite action on the cyclic adenosine monophosphate (cAMP)-dependent protein kinase A pathway (Cepeda and Levine 1998; Missale et al. 1998; Floresco et al. 2001a). It should also be mentioned that the Nac can be further distinguished in two different subregions, namely, the core and shell (Zahm and Brog 1992) that are believed to functionally differ (Cools et al. 1995; Koshikawa et al. 1996a; Jongen-Rêlo et al. 2003; Di Chiara et al. 2004; Cheng and Feenstra 2006; De Leonibus et al. 2006; Schmidt et al. 2006). This assumption is based on the connectivity of the two components of the accumbens. In particular, the shell, differently from the core, has reciprocal connections with the hypothalamus and the mesencephalon; thus, it might act to let internal physiological status-related information (hypothalamic) influence behavior directly, via the ventral pallidum, or the motivational status, via its feedback to the mesencephalon to influence other striatal DA terminal subregions (Zahm and Brog 1992). Therefore, the shell is thought to have essentially motivational functions, while the core that receives dense projections from the hippocampus and the amygdala is believed to have a more specific role in learning and memory processes (Zahm and Brog 1992; Di Ciano et al. 2001; Di Ciano and Everitt 2004; Di Chiara and Bassareo 2007; da Cunha et al. 2008). It should also be noted that the two components of the Nac have been reported to have a heterogeneous dopamine receptor distribution. In fact, although D1 receptors are ubiquitously distributed within Nac subregions, D2 receptors are denser in the core than in the shell (Lu et al. 1998).

Such findings suggest that memory consolidation might be affected in different ways by manipulation of the different DA receptor subtype within the two Nac subregions. However, there is very little experimental evidence in the literature testing this hypothesis, and the results are in some cases contradictory (Setlow and McGaugh 1998; Dalley et al. 2005; Hernandez et al. 2005). The aim of this study was, therefore, to directly compare the role of D1 and D2 receptor subtypes within the core and the shell subregions of the Nac on memory consolidation. For this purpose,
we studied the effects of immediate, or 120-min post-training D1 (SCH 23390) and D2 (sulpiride) antagonists’ injection within the Nac core and shell in mice, on aversive associative memory consolidation in the one-trial inhibitory avoidance task. We studied aversive memory because of its own clinical relevance in post-traumatic stress disorder (PTSD), a mental illness that is characterized by recurrent distressing memories of traumatic events. Interestingly, recent experimental evidence in humans demonstrated that alteration in the activity of the nucleus accumbens, together with the amygdala, the hippocampus, and the ventromedial prefrontal cortex, are strictly correlated to the development of PTSD (Liberzon et al. 1999, 2007; Pavic et al. 2003). Therefore, we think that the results of this study might help to elucidate possible neuropathophysiological mechanisms underlying this mental disorder.

Results

Histological verifications

Figure 1 shows a schematic representation of the injector placements for Experiments 1–7, indicating the most ventral point for each injector track in the different groups. Injector placements located in the core and shell of the nucleus accumbens are reported in Figure 1A (Experiments 1 and 2), Figure 1B (Experiment 3), Figure 1C (Experiments 4 and 5), and Figure 1D (Experiments 6 and 7). No major difference in injector localization distribution was evident among groups in each experiment or between the two experiments. Only those animals displaying a correct placement were included in the statistical analysis. In Figure 2 we reported pictures of representative injector positions for the core (left) and the shell (right) made on coronal sections stained with cresyl violet.

Effects of immediate post-training injections of dopamine D1 receptors antagonist, SCH 23390, into the nucleus accumbens core or shell on memory consolidation in the one-trial inhibitory avoidance task

Table 1 shows that there were no significant pre-existing differences between groups on the training latency for animals later injected into the core ($F_{(3,34)} = 1.307; P > 0.05$) or the shell ($F_{(3,29)} = 1.420; P > 0.05$). Immediate post-training injections of different doses of SCH 23390 into the nucleus accumbens core (Fig. 3A) dose dependently reduced step-through latency 24 h later ($F_{(3,34)} = 3.654; P < 0.05$). Post-hoc test revealed that the reduction was significant after the injection of both highest doses (Fig. 3A). On the contrary, immediate post-training injections of different doses of SCH 23390 into the nucleus accumbens shell (Fig. 3B) did not affect step-through latency 24 h later ($F_{(3,29)} = 0.536; P > 0.05$).

Effects of 120-min post-training injections of dopamine D1 receptors antagonist, SCH 23390, into the nucleus accumbens core on memory consolidation in the one-trial inhibitory avoidance task

In this experiment (3), we tested whether the effects of D1 receptor blockade within the core on memory consolidation were time dependent. Also, in this case there were no pre-existing (Table 1) ($F_{(1,12)} = 0.179; P > 0.05$) differences between the two groups.

Figure 1. Sketches of coronal sections from animals in the seven experiments. Each symbol represents an injector placement. The numbers indicate the anteroposterior coordinate relative to bregma according to Franklin and Paxinos (1997). Open and filled symbols are used for the shell and core, respectively. (A) Injector placements in Experiments 1 and 2; circle = vehicle, triangle = 12.5 ng/side, star = 25 ng/side; square: dose 50 ng/side SCH 23390. (B) Injector placements in Experiment 3; circle = vehicle; square: dose 50 ng/side of SCH 23390. (C) Injector placements in Experiments 4 and 5; circle = vehicle, triangle = 12.5 ng/side, star = 25 ng/side of sulpiride. (D) Injector placements in Experiments 6 and 7; circle = vehicle, star = 25 ng/side of sulpiride.
Furthermore, the highest dose of SCH 23390 (Fig. 4) that was fully effective if administered immediately post-training (Experiment 1) was completely ineffective when administered 120 min after training ($F_{1,12} = 0.001; P > 0.05$).

**Effects of immediate post-training injections of dopamine D2 receptors antagonist, sulpiride, into the nucleus accumbens core or shell on memory consolidation in the one-trial inhibitory avoidance task**

In this case also there were no significant pre-existing differences between groups (Table 1) on the training latency in the groups later injected in the core ($F_{2,25} = 0.447; P > 0.05$) or in the shell ($F_{2,25} = 0.941; P > 0.05$). Immediate post-training injections of different doses of sulpiride into the core dose dependently reduced step-through latency 24 h later ($F_{2,25} = 6.332; P < 0.05$). The post-hoc analysis revealed that the reduction was significant after the injection of the highest dose (Fig. 5A). Surprisingly, immediate post-training injections of different doses of sulpiride into the nucleus accumbens shell also significantly reduced step-through latency 24 h later ($F_{2,25} = 4.772; P < 0.05$). The post-hoc test revealed that such an effect was significant for the highest dose (Fig. 5B) and almost approached statistical significance for the lowest dose ($P = 0.067$).

**Effects of 120-min post-training injections of dopamine D2 receptors antagonist, sulpiride, into the nucleus accumbens core or shell on memory consolidation in the one-trial inhibitory avoidance task**

In these two last experiments we tested whether the impairment in step-through latency observed in Experiments 5 and 6 was due to proactive effects of the drugs rather then to memory consolidation effects. In none of these experiments did we find, pre-existing (Table 1) [Experiment 6 ($F_{1,174} = 0.257; P > 0.05$) and Experiment 7 ($F_{2,14} = .381; P > 0.05$)] or post-injection [Experiment 5, Experiment 6 ($F_{1,17} = 2.43; P > 0.05$) and Experiment 7 ($F_{1,14} = 4.2; P > 0.05$)], significant differences between groups, as shown in Figure 6, A and B.

**Discussion**

In this study we demonstrated that both subregions of the Nac, core and shell, and both dopamine receptors subtypes, D1 and D2, are involved in the consolidation of aversive associative memory. Furthermore, we dissociated for the first time in mice the specific contribution of the core and shell subregions in the same behavioral process. In particular, in the first two experiments we demonstrated that immediate post-training administrations of different doses of the D1 receptor antagonist dose dependently impaired step-through latency 24 h later when injected in the core, but not in the shell of the Nac. In the third experiment we proved that this effect was time dependent; in fact, when the highest dose of SCH 23390 was injected 120 min after training, no effects were observed 24 h later on the step-through latency. This clearly proved that the impairment induced by D1 receptors blockade within the core was not due to proactive effects of the drug, but was due to its specific action on memory consolidation. This first set of data confirmed that D1 within the Nac mediates memory consolidation in the one-trial inhibitory avoidance task (LaLumiere et al. 2005). Furthermore, it was consistent with the general role attributed to the D1 receptor in long-term memory formation and in forms of neural plasticity mediated by its activation (Smith-Roe and Kelley 2000; Di Ciano et al. 2001; Floresco et al. 2001a; Wolf et al. 2003; Mele et al. 2004; Dalley et al. 2005; Ferretti et al. 2005; Navakkode et al. 2007; Surmeier et al. 2007). Finally, our results paralleled previous results obtained using an appetitive Pavlovian associative task, demonstrating a clear contribution of D1 receptor activation within the core subregion in memory consolidation (Dalley et al. 2005). We expanded this experimental evidence by demonstrating that aversive memory is independent of D1 receptor activation within the shell.

In the second set of experiments (Experiments 4–7) we tested the role of D2 receptors in aversive memory consolidation. The results of these experiments clearly demonstrated that immediate post-training D2 receptors blockade within the core or the shell impaired passive avoidance memory 24 h later. This effect was once again time dependent, since 120-min post-training administration was ineffective (Experiments 6 and 7). On the basis of our data, we cannot exclude that the generalized effect of sulpiride in the two regions was due to a spread of the drug from the core to the shell or vice versa. However, this hypothesis seems unlikely if we consider the low injection volume (0.2 µL/side) used and the fact that the same volume of SCH 23390 solution produced region-specific effects. More importantly, it was previously demonstrated

### Table 1. Step-through latencies on training day

| Experiment | Nac Subregion | Treatment | Groups | N | Latency |
|------------|--------------|-----------|--------|---|---------|
| Experiment 1 Core | SCH 23390 | Vehicle | 9 | 5.1 ± 1.1 |
| | | 12.5 | 10 | 4.6 ± 0.7 |
| | | 25 | 11 | 4.4 ± 0.5 |
| | | 50 | 8 | 3 ± 0.5 |
| Experiment 2 Shell | SCH 23390 | Vehicle | 8 | 4.9 ± 0.7 |
| | | 12.5 | 9 | 5.8 ± 0.8 |
| | | 25 | 8 | 4.2 ± 0.5 |
| | | 50 | 8 | 3.8 ± 0.7 |
| Experiment 3 Core | SCH 23390 | Vehicle | 6 | 6.5 ± 2.3 |
| | | 50 | 8 | 5.5 ± 1.1 |
| Experiment 4 Core | Sulpiride | Vehicle | 12 | 4.7 ± 0.6 |
| | | 12.5 | 11 | 5.9 ± 1.1 |
| | | 25 | 15 | 5.5 ± 0.9 |
| Experiment 5 Shell | Sulpiride | Vehicle | 10 | 6.7 ± 1.2 |
| | | 12.5 | 9 | 5.2 ± 1 |
| | | 25 | 9 | 4.7 ± 0.9 |
| | | 4.4 ± 0.7 |

| | | 8 | 2.9 ± 0.5 |
| | | 25 | 8 | 3.4 ± 0.6 |

Latency in seconds (± SEM) to step-through on the training day for the different groups in all experiments. There were no pre-existing differences between groups.
behavioral evidence demonstrated that D2, but not D1 receptors partially supports this view. Indeed, earlier electrophysiological evidence parallels during memory consolidation. Electrophysiological evidence parallels contextual information carried by hippocampal input to the Nac.

Within the Nac core accomplish different operations guided Pavlovian learning. This interpretation implies that D1 and MWM and the passive avoidance task, but not to solve the cue-to acquire the spatial-contextual component needed to solve the

activation within the core (Dalley et al. 2005). However, it might also be that D2 receptors activation within the core is necessary to consolidate complex forms of association. The simplest explanation for these different results is that aversive, but not appetitive memory requires D2 activation within the core (Dalley et al. 2005). However, it might also be that D2 receptors activation within the core are necessary to acquire the spatial-contextual component needed to solve the MWM and the passive avoidance task, but not to solve the cue-guided Pavlovian learning. This interpretation implies that D1 and D2 receptors within the core accomplish different operations on memory consolidation, and that D2 receptors gates spatial-contextual information carried by hippocampal input to the Nac during memory consolidation. Electrophysiological evidence partially supports this view. Indeed, earlier electrophysiological and behavioral evidence demonstrated that D2, but not D1 receptors

that the concentration of sulpiride that is needed to reach a full pharmacological effect at a distance of 1 mm from the injection site is in the range of 1 to 10 mM, which is very high when compared with the pharmacological efficacy of these compounds, and the doses used in this study (Westerink and De Vries 2004). It is interesting to note that despite the higher density of D2 receptors in the shell than in the core, sulpiride was more effective in the former. This suggests that passive avoidance memory is more sensitive to D2 receptors activation in the core than in the shell.

Figure 3. Effects of immediate post-training injections of vehicle or different doses of SCH 23390 within the Nac core (A) or shell (B) on step-through latency 24 h later. (*) P < 0.05 SCH 23390 vs. vehicle.

Figure 4. Effects of 120-min post-training injections of vehicle or 50 ng/side of SCH 23390 within the Nac core on step-through latency 24 h later.

All together, the results of focal administration studies suggest that D1 receptors within the Nac core might be activated to integrate all forms of memory processed. On the contrary, D2 receptor activation might gait the control of hippocampal inputs on the neuronal activation induced by amygdala inputs to the Nac core immediately after learning, during memory consolidation. This might explain the ubiquitous role of D1 receptors within the core regardless of the behavioral task used, and the specific contribution of D2 receptors in hippocampal-dependent memory tasks (Setlow and McGaugh 1998; Smith-Roe and Kelley 2000; Dalley et al. 2005; Hernandez et al. 2005).

A strictly related issue is whether D2 receptors activation within the core and shell subregions have different roles in the consolidation of the information acquired in the one-trial inhibitory avoidance task. We suggested that D2 receptors blockade in the core might affect long-term context-reward memory formation by favoring the integration of contextual information coming from the hippocampus to emotional information coming from the basolateral amygdala, which are all necessary to perform the task. The injection sites in our study, indeed, targeted the medial core, where inputs from the basolateral amygdala, the hippocampus, and the prefrontal cortex converge (Mulder et al. 1998). On the contrary, the shell was generally targeted more ventrally, where the influence of the basolateral amygdala, the hypothalamus, and the infralimbic cortex, thus of internal status-related information, might predominate (as compared with context related once). Recent evidence demonstrated that the DA within the shell mediates not only memory consolidation but also memory improvement in the passive avoidance task induced by dopamine injections within the core or the shell improve memory consolidation in the passive avoidance task, and that D2 receptors blockade in the two subregions impairs memory consolidation in the Morris water maze (MWM) task (Setlow and McGaugh 1998; LaLumiere et al. 2005). Nevertheless, this effect seems to be task dependent, since D1, but not D2 receptors blockade within the core has been reported to impair appetitive Pavlovian memory consolidation (Dalley et al. 2005).

To our knowledge this is the first experimental evidence to date demonstrating that activation of both DA receptors subtypes within the core are a necessary condition to consolidate complex forms of association. The simplest explanation for these different results is that appetitive, but not aversive memory requires D2 activation within the core (Dalley et al. 2005). However, it might also be that D2 receptors activation within the core are necessary to acquire the spatial-contextual component needed to solve the MWM and the passive avoidance task, but not to solve the cue-guided Pavlovian learning. This interpretation implies that D1 and D2 receptors within the core accomplish different operations on memory consolidation, and that D2 receptors gates spatial-contextual information carried by hippocampal input to the Nac during memory consolidation. Electrophysiological evidence partially supports this view. Indeed, earlier electrophysiological and behavioral evidence demonstrated that D2, but not D1 receptors...
dopamine stimulation within the basolateral amygdala (LaLumiere et al. 2005). We speculate that DA within the shell might affect memory formation and memory strength by modulating the motivational impact of the stimuli, and that this effect is mediated by D2 receptors activation.

In conclusion, we confirm a general role of dopamine and both DA receptors subtypes within the Nac in conditional memory consolidation (Lorenzini et al. 1995; Setlow and McGaugh 1999). It is interesting to note that systemic administration studies of DAergic drugs consistently confirm the role of both receptors subtypes in aversive memory consolidation. In fact, systemic administration of D1 and D2 antagonists in CD1 outbred mice (Castellano et al. 1991) has been proven to block memory consolidation in the one-trial passive avoidance task. However, systemic blockade of DA receptors subtypes impaired and improved aversive memory consolidation in C57BL/6J and DBA/2J inbred mice, respectively, while opposite effects were observed with DAergic agonists (Cestari et al. 1992). Although no focal administration studies have been performed yet, these two inbred mouse strains are known to differ in their reactivity of the Nac dopaminergic system to systemic administration of DAergic drugs (Zocchi et al. 1998; Ventura et al. 2004), therefore suggesting, once again, the Nac as a possible neural substrate for this genotype-dependent memory effect of DA.

These data have their own broad relevance, since they prove that DA in the Nac is necessary not only to guide attention and ongoing behavior, but also for the short- or long-term storage of conditional associations or spatial information (Ploeger et al. 1994; Setlow and McGaugh 1998; Di Ciano et al. 2001; Mele et al. 2004; Dalley et al. 2005; Perretti et al. 2005; LaLumiere et al. 2005). In other words, it is also involved in off-line cognitive processing. In addition, we demonstrated that dopamine receptors subtypes, D1 and D2, can modulate this process differently depending on the Nac subregion, the core and shell. These results, in our opinion, also have a great clinical relevance, since they parallel experimental evidence in humans demonstrating that during symptoms, provocation activation in the region of the left amygdala/nucleus accumbens occurs only in PTSD-affected patients, but not in combat control or normal control subjects (Liberzon et al. 1999). Since antipsychotics are already in use for a variety of psychiatric disorders in humans, the results of this study supports their potential use for early intervention after a traumatic experience in humans in order to prevent the development of post-traumatic stress disorder. Therefore, the demonstration that the D2 antagonist consistently blocks memory consolidation for aversive events might also have therapeutic implications.

Materials and Methods

Animals

The subjects were adult CD1 male outbred mice obtained from Charles River. Upon arrival, mice were housed in groups of 12 in standard breeding cages (46 × 26 × 21.8 cm), placed in a rearing room at a constant temperature (22 ± 1°C), and maintained on a 12 h light/dark cycle with food and water available ad libitum. At the time of surgery they were 9–12 wk old. Every possible effort was made to minimize animal suffering, and all procedures were in strict accordance with the European Communities Council directives (86/609/EEC) and regulations on the use of animals in research and NIH guidelines on animal care.

Surgery

Mice were anesthetized by intraperitoneal injection of chloral hydrate (500 mg/kg; Fluka) and placed in a stereotaxic apparatus (David Kopf Instruments) with mouse adapter and lateral ear bars. The mice were bilaterally implanted with 7-mm-long stainless-steel cannulae 2 mm dorsal to the nucleus accumbens core or the nucleus accumbens shell. The stereotaxic coordinates used were AP, +1.5 mm; L, ±1 mm, DV, −2.1 mm, and AP, +1.5 mm, L, ±0.5 mm, DV, −2.6 mm relative to bregma, respectively, for the core and the shell, according to the atlas of Franklin and Paxinos

Figure 5. Effects of immediate post-training injections of vehicle or different doses of sulpiride within the Nac core (A) or shell (B) on step-through latency 24 h later. (*) P < 0.05 sulpiride vs. vehicle.

Figure 6. Effects of 120-min post-training injections of vehicle or 25 ng/side of sulpiride within the Nac core (A) or shell (B) on step-through latency 24 h later.
Drugs and injection procedure

The doses of dopamine antagonists were chosen based on preliminary experiments and previous studies (Mele et al. 2004; Ferretti et al. 2005). The D1 receptor antagonist, SCH 23390 (SCH; RBI), was dissolved in saline solution (0.9% NaCl in distilled water). Sulpiride (SULP; Sigma-Aldrich) was used as the D2 antagonist; it was dissolved in a drop of acetic acid and then diluted with saline solution to the final concentration, and the pH was adjusted to 7.0 with NaOH. All solutions were administered in a volume of 0.2 µL/side. Drug-injected animals were always compared with mice injected with the same volume of the same vehicle solution used to dilute the different drugs. An injection needle was inserted into the guide cannula, which was connected by plastic tubing to a 2-µL Hamilton syringe; the process took 2 min, with one additional minute to allow diffusion. In Experiments 1, 2, 4, and 5 drug injection was performed immediately after training, while in the remaining experiments drugs were injected 120 min after training.

Experiments

In the first two experiments injections of the D1 receptor antagonist, SCH 23390, within the Nac core (Experiment 1) and the shell (Experiment 2) subregions were performed immediately post-training. Four different experimental groups, one for each experiment, were injected with vehicle, 12.5, 25, or 50 ng/side of SCH 23390. A further experiment (Experiment 3) tested the effects of 120-min post-training injections of D1 receptor antagonist, SCH 23390, within the Nac core, by using two different experimental groups injected with vehicle or 50 ng/side of SCH 23390. In Experiments 4 and 5, immediate post-training injections of D2 receptor antagonist, sulpiride, were administered within the Nac core and the shell, respectively. Three different experimental groups were used, one for each experiment, injected with vehicle, 12.5 or 25 ng/side of sulpiride. In the last two experiments, D2 antagonist, sulpiride, was administered 120 min post-training in the core (Experiment 6) and in the shell (Experiment 7). Two different experimental groups, one for each experiment, were injected with vehicle or 25 ng/side of sulpiride.

Histological analysis

At the completion of the experiments, mice were sacrificed with an overdose of chloral hydrate, and the brains were removed and fixed in a 4% formaldehyde solution. Cannula placements were determined by examining serial 60-µm coronal sections stained with cresyl violet.
