(Dated: today)

Recently, first limits on putative Lorentz invariance violation coefficients in the pure gravity sector were determined by the reanalysis of short-range gravity experiments. Such experiments search for new physics at sidereal frequencies. They are not, however, designed to optimize the signal strength of a Lorentz invariance violation force; in fact the Lorentz violating signal is suppressed in the planar test mass geometry employed in those experiments. We describe a short-range torsion pendulum experiment with enhanced sensitivity to possible Lorentz violating signals. A periodic, striped test mass geometry is used to augment the signal. Careful arrangement of the phases of the striped patterns on opposite ends of the pendulum further enhances the signal while simultaneously suppressing the Newtonian background.

I. INTRODUCTION

Local Lorentz symmetry is a solid foundation of General Relativity (GR), which is a classical theory and may demand some changes in its foundational structure to merge gravity with quantum mechanics. There are many theoretical scenarios in which this symmetry might be broken. Even if local Lorentz invariance is exact in the underlying theory of quantum gravity, spontaneous breaking of this symmetry may occur, leading to miniscule observable effects [1, 2]. Additionally, Lorentz invariance violations (LIV) may be relatively large but hidden from the many experiments to date [3, 4], which set very tight bounds across many physical sectors (including the photon, proton, electron and other particle sectors). Thus, in general, the investigation of LIV is a valuable tool to probe the foundations of GR [3, 6] without preconceived notions of the numerical sensitivity.

A more recent area for searching for LIV is in the pure gravity sector [7], with some recent first bounds utilizing either short-range torsional experiments [8, 10], planetary motion [11], gravitational Cerenkov radiation [12] and gravitational wave dispersion [13]. Short-range experiments at Indiana University (IU) [8] and Huazhong University of Science and Technology (HUST) [14] have achieved sensitivities at the level of $10^{-7}$ to $10^{-8}$ m$^2$ respectively, to individual coefficients controlling these types of gravitational LIV. More recently a combined analysis from the same two experimental groups permitted the first simultaneous limits on the 14 nonrelativistic LIV coefficients in the pure gravity sector, at the level of $10^{-9}$ m$^2$ [10]. However, these experiments use planar geometry, as they are designed primarily to search for Yukawa-type non-Newtonian gravity [12]. The LIV force between two parallel, coaxial plates is suppressed, and in fact vanishes in the limit that one plate has infinite area [8].

In this work, we analyse a modified short-range gravity experiment with enhanced sensitivity to LIV. The phase of the striped pattern on the pendulum test mass is shifted relative to the pattern of the immediately opposite source mass. An ”asymmetric” design, in which this phase relationship is reversed for the pair of masses on the opposite end of the pendulum, further enhances the LIV signal and suppresses the Newtonian background.

II. LORENTZ INVARIANCE VIOLATION WITH QUADRATIC CURVATURE COUPLINGS

It has been shown that in gravitation experiments, the perturbative corrections to the Newtonian potential between two test masses $m_1$ and $m_2$ in the Standard-Model Extension (SME) is given by [7]

$$V_{LV}(\vec{r}) = -G \frac{m_1 m_2}{|\vec{r}|^3} \bar{k}(\vec{r}, T).$$

(1)

Here the vector $\vec{r} = \vec{r}_1 - \vec{r}_2$ separates $m_1$ and $m_2$, and

$$\bar{k}(\vec{r}, T) = \frac{3}{2} (\vec{k}_{eff})_{jk} \delta_{jk} - 9 (\vec{k}_{eff})_{jk} \delta_{jk} \delta_{kl} \delta_{lm} \frac{15}{2} (\vec{k}_{eff})_{jk} \delta_{jk} \delta_{lm} \delta_{kl}.$$

(2)

with dimensions of squared length, containing 15 independent degrees of freedom of which 14 are measurable [11].
The Sun-centered celestial-equatorial frame has become the convention for reporting results from experimental searches for the LIV coefficients across all SME sectors. In this frame the Z axis points along the direction of the Earth’s rotation axis and the X axis points towards the vernal equinox \( \text{v} \). Thus, the rotation of the Earth modulates the LIV coefficients in the laboratory frame, producing putative sidereal signals in the experimental data \( \text{v2} \). Ignoring any boost dependence (suppressed by \( 10^{-9} \)), the conversion from the Sun-centered frame \((X, Y, Z)\) to the laboratory frame \((x, y, z)\) with \(x\) axis pointing to local south and \(z\) axis to the zenith can be implemented by the time-dependent rotation

\[
R^{\!ij} = \begin{pmatrix}
\cos \chi \cos \omega_b T & \cos \chi \sin \omega_b T & -\sin \chi \\
-\sin \omega_b T & \cos \omega_b T & 0 \\
\sin \chi \cos \omega_b T & \sin \chi \sin \omega_b T & \cos \chi
\end{pmatrix}.
\]

Here the angle \( \chi \) is the colatitude of the laboratory and \( \omega_b \approx 2\pi/(23.73 \text{ h}) \) is the Earth’s sidereal frequency. The sidereal time \( T \)-dependent coefficients \( (\bar{k}_{eff})_{jklm} \) are thus related to the constant coefficients \( (k_{eff})_{JKLM} \) in the Sun-centered frame by

\[
(\bar{k}_{eff})_{jklm} = R^{\!ij} R^{\!kl} R^{\!lm} (k_{eff})_{JKLM}.
\]

Therefore, the inverse-cube potential for LIV is oscillatory with \( T \) and includes components up to the fourth harmonic of \( \omega_b \) in laboratory gravity experiments. Equivalently, the LIV force between two point masses can be expected to vary with frequencies up to and including the fourth harmonic of \( \omega_b \). Thus, \( \bar{k}(\bar{r}, T) \) can be expressed as the following Fourier series

\[
\tilde{k}(\bar{r}, T) = c_0 + \sum_{m=1}^{4} [c_m \cos(m\omega_b T) + s_m \sin(m\omega_b T)].
\]

The nine Fourier amplitudes in this expression are functions of \((k_{eff})_{JKLM}\) according to Eq. (4).

In short-range experiments, one can compute the nine Fourier coefficients from time-dependent force data to search for LIV. To simplify the analysis, we separate the even and odd harmonics in Eq. 5 with the introduction of the modified coefficients \( \bar{k}_j \) where \( j = 0, 1, 2, \cdots, 14 \). The \( \bar{k}_j \) are 15 independent linear combinations of the \((k_{eff})_{JKLM}\). The first nine coefficients represent even harmonics,

\[
\begin{pmatrix}
\bar{k}_0 \\
\bar{k}_1 \\
\bar{k}_2 \\
\bar{k}_3 \\
\bar{k}_4 \\
\bar{k}_5 \\
\bar{k}_7 \\
\bar{k}_8
\end{pmatrix} =
\begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 1 & 2 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & -1 & 0 & 0 & 0 \\
0 & 1 & -1 & 6 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & -1 & 1 & 0
\end{pmatrix}
\begin{pmatrix}
\bar{k}_{eff} \text{ZZZZ} \\
\bar{k}_{eff} \text{XXXX} \\
\bar{k}_{eff} \text{YYYY} \\
\bar{k}_{eff} \text{XXYY} \\
\bar{k}_{eff} \text{XZZZ} \\
\bar{k}_{eff} \text{YZZZ} \\
\bar{k}_{eff} \text{XYYZ} \\
\bar{k}_{eff} \text{XYYZ}
\end{pmatrix}.
\]

The remaining coefficients represent odd harmonics,

\[
\begin{pmatrix}
\bar{k}_9 \\
\bar{k}_{10} \\
\bar{k}_{11} \\
\bar{k}_{12} \\
\bar{k}_{13} \\
\bar{k}_{14}
\end{pmatrix} =
\begin{pmatrix}
1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 1 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 1
\end{pmatrix}
\begin{pmatrix}
\bar{k}_{eff} \text{XZZZ} \\
\bar{k}_{eff} \text{YZZZ} \\
\bar{k}_{eff} \text{XXXX} \\
\bar{k}_{eff} \text{YZZZ} \\
\bar{k}_{eff} \text{XXYY} \\
\bar{k}_{eff} \text{XYYZ}
\end{pmatrix}.
\]

Combining the transformation matrix \( R^{\!ij} \) and Eqs. (6) and (7), the nine Fourier amplitudes in Eq. (5) take the explicit form:

\[
\begin{align*}
c_0 &= \alpha_0 \bar{k}_0 + \alpha_1 \bar{k}_1 + \alpha_2 \bar{k}_2 \\
c_2 &= \alpha_3 \bar{k}_3 + \alpha_4 \bar{k}_4 + \alpha_5 \bar{k}_5 + \alpha_6 \bar{k}_6 \\
s_2 &= -\frac{1}{2} \alpha_3 \bar{k}_3 - \frac{1}{2} \alpha_6 \bar{k}_6 + 2 \alpha_3 \bar{k}_5 + 2 \alpha_4 \bar{k}_6 \\
c_4 &= \alpha_7 \bar{k}_7 + \alpha_8 \bar{k}_8 \\
s_4 &= \frac{1}{4} \alpha_8 \bar{k}_7 - 4 \alpha_7 \bar{k}_8
\end{align*}
\]

for even harmonics, involving 9 functions \( \alpha_j(\bar{r}, \chi) \) with \( j = 0, 1, 2, \cdots, 8 \), and

\[
\begin{align*}
c_1 &= \alpha_9 \bar{k}_9 + \alpha_{10} \bar{k}_{10} + \alpha_{11} \bar{k}_{11} + \alpha_{12} \bar{k}_{12} \\
s_1 &= -\alpha_9 \bar{k}_9 + \alpha_{10} \bar{k}_{10} - \alpha_{12} \bar{k}_{12} + \alpha_{11} \bar{k}_{12} \\
c_3 &= \alpha_{13} \bar{k}_{13} + \alpha_{14} \bar{k}_{14} \\
s_3 &= \alpha_{14} \bar{k}_{13} - \alpha_{13} \bar{k}_{14}
\end{align*}
\]

for odd harmonics, involving 6 functions \( \alpha_j(\bar{r}, \chi) \) with \( j = 9, 10, \cdots, 14 \). The Fourier amplitude \( c_0 \) is a linear combination of \( \bar{k}_0 \), \( \bar{k}_1 \), and \( \bar{k}_2 \). The amplitudes \( c_2 \) and \( s_2 \) are linear combinations of \( \bar{k}_3 \), \( \bar{k}_4 \), \( \bar{k}_5 \), and \( \bar{k}_6 \). Amplitudes \( c_4 \) and \( s_4 \) are the linear combinations of \( \bar{k}_7 \) and \( \bar{k}_8 \). Similar relations apply to the odd harmonics.

By introducing the rotation

\[
\begin{align*}
\tilde{x} &= x \cos \chi + z \sin \chi \\
\tilde{z} &= -x \sin \chi + z \cos \chi
\end{align*}
\]
the corresponding expressions $\alpha_j(\hat{r}, \chi)$, can be written as

$$
\begin{align*}
\alpha_0(\hat{r}, \chi) &= \frac{3}{2} - \frac{9}{2} \frac{z^2}{r^2} + \frac{15}{2} \frac{z^4}{r^4} \\
\alpha_1(\hat{r}, \chi) &= -\frac{3}{16} \frac{9}{r^2} \frac{z^2}{r^2} - \frac{45}{16} \frac{z^4}{r^4} \\
\alpha_2(\hat{r}, \chi) &= -\frac{3}{2} + \frac{18}{r^2} \frac{z^2}{r^2} - \frac{45}{2} \frac{z^4}{r^4} \\
\alpha_3(\hat{r}, \chi) &= -\frac{9}{2} \frac{z^2}{r^2} - \frac{9}{2} \frac{z^4}{r^4} \\
\alpha_4(\hat{r}, \chi) &= -\frac{9}{2} \frac{z^2}{r^2} + \frac{15}{4} \frac{x^4 - y^4}{r^4} \\
\alpha_5(\hat{r}, \chi) &= \frac{-\bar{y}y}{r^2} - \frac{15}{2} \frac{z^2 + y^2}{r^2} \\
\alpha_6(\hat{r}, \chi) &= 18 \frac{-\bar{y}y}{r^2} - \frac{1}{15} \frac{z^2 + y^2}{r^2} \\
\alpha_7(\hat{r}, \chi) &= 15 \frac{-\bar{y}y}{r^2} - \frac{1}{15} \frac{z^2 + y^2}{r^2} \\
\alpha_8(\hat{r}, \chi) &= \frac{-\bar{z}z}{r^2} - \frac{1}{15} \frac{z^2 + y^2}{r^2} \\
\alpha_9(\hat{r}, \chi) &= \frac{-\bar{z}z}{r^2} - \frac{15}{2} \frac{z^2 + y^2}{r^2} \\
\alpha_{10}(\hat{r}, \chi) &= \frac{\bar{z}y}{r^2} - \frac{15}{2} \frac{z^2 + y^2}{r^2} \\
\alpha_{11}(\hat{r}, \chi) &= \frac{-\bar{z}z}{r^2} - \frac{15}{2} \frac{z^2 + y^2}{r^2} \\
\alpha_{12}(\hat{r}, \chi) &= \frac{-\bar{z}z}{r^2} - \frac{15}{2} \frac{z^2 + y^2}{r^2} \\
\alpha_{13}(\hat{r}, \chi) &= \frac{-\bar{z}z}{r^2} - \frac{15}{2} \frac{z^2 + y^2}{r^2} \\
\alpha_{14}(\hat{r}, \chi) &= \frac{-\bar{z}z}{r^2} - \frac{15}{2} \frac{z^2 + y^2}{r^2}
\end{align*}
$$

From Eq. (11), we obtain

$$3\alpha_0 + 8\alpha_1 + 2\alpha_2 = 0, \quad (12)$$

and the constant term $c_0$ can be expressed

$$c_0 = \alpha_1(\tilde{k}_1 - \frac{8}{3} \tilde{k}_0) + \alpha_2(\tilde{k}_2 - \frac{2}{3} \tilde{k}_0). \quad (13)$$

This means that the nine Fourier amplitudes $c_j$ and $s_j$ can be expressed as linear combinations of the $(\tilde{k}_{eff})_{JKLM}$ via the reduced set of 14 independent functions $\alpha_j(\hat{r}, \chi)$ with $j = 1, 2, \cdots, 14$. In other words, only 14 degrees of freedom of $(\tilde{k}_{eff})_{JKLM}$ are independently measurable in short-range experiments. The remaining one is the double trace $(\tilde{k}_{eff})_{JKLM}$, which is rotation invariant, and produces only a contact correction to the usual Newtonian force. In summary, we have introduced the $\tilde{k}_j$ to decompose the 14 dimensional $(\tilde{k}_{eff})_{JKLM}$ into 5 subspaces (Eq. 8). The main advantage is that it isolates the different harmonics of the LIV, making unique harmonic violation signals correspond to different subspaces.

III. MEASURABLE COEFFICIENTS IN LORENTZ INVARIANCE VIOLATION

The double trace $(\tilde{k}_{eff})_{JKLM}$ is a rotational scalar, here denoted by $u$. After separating this scalar degree of freedom, we decompose the coefficients $(\tilde{k}_{eff})_{JKLM}$ for the LIV according to

$$\langle \tilde{k}_{eff} \rangle_{JKLM} = \langle \tilde{k}_{eff} \rangle_{JKLM} + \frac{u}{15} \delta_{JK} \delta_{LM} + \delta_{JL} \delta_{KM} + \delta_{JM} \delta_{KL},$$

(14)

with $(\tilde{k}_{eff})_{JKLM} = 0$. It is straightforward to show that the scalar part, also denoted $\frac{1}{15} u(\delta_{JK} \delta_{LM} + \delta_{JL} \delta_{KM} + \delta_{JM} \delta_{KL})$ in the laboratory frame, has no contribution to the $\tilde{k}(\hat{r}, T)$ in Eq. (2). Therefore, the 14 independently measurable coefficients are $(\tilde{k}_{eff})_{JKLM}$. Equivalently, we may adopt $(\tilde{k}_{eff})_{JKLM} - \frac{1}{15} (\tilde{k}_{eff})_{ZZZZ} (\delta_{JKLM} + \delta_{JL} \delta_{KM} + \delta_{JM} \delta_{KL})$ for the 14 measurable coefficients in Sun-centered frame, since the scalar part is not observable in Eq. (2).

Combining Eqs. (13) and (6), we redefine the eight $\tilde{k}_j$ with $j = 1, 2, \cdots, 8$ as

$$
\begin{pmatrix}
\tilde{k}_1 \\
\tilde{k}_2 \\
\tilde{k}_3 \\
\tilde{k}_4 \\
\tilde{k}_5 \\
\tilde{k}_6 \\
\tilde{k}_7 \\
\tilde{k}_8 \\
\end{pmatrix}
= R_{even}
\begin{pmatrix}
(k_{eff})_{XXXX} - (k_{eff})_{ZZZZ} \\
(k_{eff})_{YYYY} - (k_{eff})_{ZZZZ} \\
(k_{eff})_{XXYY} - \frac{1}{3} (k_{eff})_{ZZZZ} \\
(k_{eff})_{XXXZ} - \frac{1}{3} (k_{eff})_{ZZZZ} \\
(k_{eff})_{XYZZ} - \frac{1}{3} (k_{eff})_{ZZZZ} \\
(k_{eff})_{XXYZ} - \frac{1}{3} (k_{eff})_{ZZZZ} \\
(k_{eff})_{XXZY} \\
(k_{eff})_{XYZZ} \\
\end{pmatrix}
\quad (15)
$$

with matrix

$$R_{even} =
\begin{pmatrix}
1 & 1 & 2 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 \\
1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
-1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & -1 & 0 \\
\end{pmatrix}
\quad (16)
$$

for even harmonics. Inserting Eqs. (15) and (16) into Eq. (8), five Fourier amplitudes can be expressed as
The six $\tilde{k}_j$ with $j = 9, 10, \ldots, 14$ defined in Eq. (7), need not be changed. According to Eq. (9), the Fourier amplitudes for the odd harmonics are

$$
\begin{pmatrix}
\alpha_9 & \alpha_10 & \alpha_{11} & \alpha_{12} & \alpha_{13} & \alpha_{14} & \alpha_{15} & \alpha_{16} \\
-\alpha_{10} & -\alpha_9 & -\alpha_{11} & -\alpha_{12} & \alpha_{13} & \alpha_{14} & \alpha_{15} & \alpha_{16} \\
0 & 0 & \alpha_{13} & \alpha_{14} & -3\alpha_{14} & -3\alpha_{13} & 0 & 0 \\
0 & 0 & \alpha_{14} & -\alpha_{13} & 3\alpha_{13} & -3\alpha_{14} & 0 & 0 \\
\end{pmatrix}
= \begin{pmatrix}
\alpha_1 & \alpha_2 & \alpha_3 & \alpha_4 & \alpha_5 & \alpha_6 & \alpha_7 & \alpha_8 \\
\alpha_3 & -\alpha_3 & 0 & \alpha_4 & -\alpha_4 & \alpha_5 & \alpha_5 & \alpha_6 \\
-\alpha_7 & -\alpha_7 & 6\alpha_7 & 0 & 0 & \alpha_8 & -\alpha_8 & 0 \\
-\frac{1}{4}\alpha_8 & -\frac{1}{4}\alpha_8 & \frac{3}{2}\alpha_8 & 0 & 0 & -4\alpha_7 & 4\alpha_7 & 0 \\
\end{pmatrix}
\begin{pmatrix}
(k_{eff})_{XXXY} \\
(k_{eff})_{YXXX} \\
(k_{eff})_{XYZZ} \\
(k_{eff})_{XZXY} \\
\end{pmatrix}.
$$

where we have introduced

$$
\begin{align}
\beta_1 &= \frac{11}{3}\alpha_1 + \frac{2}{3}\alpha_2 \\
\beta_2 &= \frac{16}{3}\alpha_1 + \frac{7}{3}\alpha_2.
\end{align}
$$

The relation between the four Fourier amplitudes and $(\tilde{k}_{eff})_{J_{KLM}}$ is similar to Eqs. (17) and (18), with $\alpha_1$ and $\alpha_2$ being replaced by $\beta_1$ and $\beta_2$, respectively. The explicit expressions for odd and even harmonics are

$$
\begin{pmatrix}
\alpha_9 & \alpha_10 & \alpha_{11} & \alpha_{12} & \alpha_{13} & \alpha_{14} & \alpha_{15} & \alpha_{16} \\
-\alpha_{10} & -\alpha_9 & -\alpha_{11} & -\alpha_{12} & \alpha_{13} & \alpha_{14} & \alpha_{15} & \alpha_{16} \\
0 & 0 & \alpha_{13} & \alpha_{14} & -3\alpha_{14} & -3\alpha_{13} & 0 & 0 \\
0 & 0 & \alpha_{14} & -\alpha_{13} & 3\alpha_{13} & -3\alpha_{14} & 0 & 0 \\
\end{pmatrix}
= \begin{pmatrix}
\beta_1 & \beta_1 & 2\beta_1 & \beta_2 & \beta_2 & 0 & 0 & 0 \\
\beta_1 & -\beta_1 & 0 & \beta_2 & -\beta_2 & 0 & 0 & 0 \\
-\frac{1}{4}\alpha_8 & -\frac{1}{4}\alpha_8 & \frac{3}{2}\alpha_8 & 0 & 0 & -4\alpha_7 & 4\alpha_7 & 0 \\
-\frac{1}{4}\alpha_8 & -\frac{1}{4}\alpha_8 & \frac{3}{2}\alpha_8 & 0 & 0 & -4\alpha_7 & 4\alpha_7 & 0 \\
\end{pmatrix}
\begin{pmatrix}
(k_{eff})_{XXXY} \\
(k_{eff})_{YXXX} \\
(k_{eff})_{XYZZ} \\
(k_{eff})_{XZXY} \\
\end{pmatrix}.
$$

respectively. In the following analysis, we use Eqs. (17) and (18) to search for LIV.
IV. LORENTZ INVARIENCE VIOLATING TORQUE IN TORSION PENDULUM EXPERIMENTS

Most laboratory gravity experiments employ a low-frequency torsion pendulum. Fig.1 shows a simple I-shaped torsion pendulum consisting of three rectangular glass blocks. The fiber is under tension from the weight of the pendulum, which is, in turn, free to rotate about the axis of the fiber. Specialized test masses, in the form of thin plates with horizontal stripes of alternating density, are attached to the vertical sides of the blocks (e.g., Wt1 in Fig. 1). If a force acts on one test mass (generated, for example, by another striped plate Ws1 brought into close proximity), the fiber will twist. The angular deflection reveals the interaction strength. The restoration torsion constant of a thin fiber can be quite small, typically on the order of \(10^{-9} \text{Nm/rad}\).

We now consider the LIV interaction between the test mass Wt1 and source mass Ws1, with density \(\rho_1\) and \(\rho_2\) respectively. In the SME laboratory frame, the origin is at the center of the pendulum. Supposing the test mass element \(dm_1 = \rho_1 dV_1\) to be located at position \((x_1, y_1, z_1)\) with \(x_1 = L_1 \cos \theta\) and \(y_1 = L_1 \sin \theta\) and taking the derivative with respect to \(\theta\), we can obtain the LIV torque on the torsion pendulum as

\[
\tau_{LV} = G \rho_1 \rho_2 \int dV_1 dV_2 \frac{\partial}{\partial \theta} \frac{\tilde{k}(\hat{r}, T)}{r^3} = G \rho_1 \rho_2 \int dV_1 dV_2 \left[ x_1 \frac{\partial}{\partial y_1} \frac{\tilde{k}(\hat{r}, T)}{r^3} - y_1 \frac{\partial}{\partial x_1} \frac{\tilde{k}(\hat{r}, T)}{r^3} \right]
\]

with the source mass element \(dm_2 = \rho_2 dV_2\) located at position \((x_2, y_2, z_2)\). The six-dimensional integration is performed over the volumes for test mass \(m_1\) and source mass \(m_2\).

We introduce the following 14 transfer coefficients \(\Lambda_j\) for \(j = 1, 2, \cdots, 14\):

\[
\Lambda_j = G \rho_1 \rho_2 \int \frac{\partial}{\partial \theta} \frac{\alpha_j(\hat{r}, \chi)}{r^3} dV_1 dV_2.
\]

Using these coefficients in place of the \(\alpha_j\) in Eqs. (17) and (18), we may denote the LIV torque \(\tau_{LV}\) on the pendulum by

\[
\tau_{LV} = C_0 + \sum_{m=1}^{4} \left[ C_m \cos(m\omega_{\odot}T) + S_m \sin(m\omega_{\odot}T) \right].
\]

The nine Fourier amplitudes of torque are

\[
\begin{pmatrix}
C_0 \\
C_2 \\
S_2 \\
C_4 \\
S_4
\end{pmatrix} = \begin{pmatrix}
\Lambda_1 & \Lambda_1 & 2\Lambda_1 & \Lambda_2 & \Lambda_2 & 0 & 0 & 0 & \Lambda_3 & -\Lambda_3 & 0 & \Lambda_4 & -\Lambda_4 & \Lambda_5 & \Lambda_5 & \Lambda_6 \\
-\frac{2}{3}\Lambda_5 & \frac{1}{3}\Lambda_5 & 0 & -\frac{2}{3}\Lambda_6 & \frac{1}{3}\Lambda_6 & 2\Lambda_3 & 2\Lambda_3 & 2\Lambda_4 & -\Lambda_7 & -\Lambda_7 & 6\Lambda_7 & 0 & 0 & \Lambda_8 & -\Lambda_8 & 0 \\
-\frac{2}{3}\Lambda_8 & -\frac{1}{3}\Lambda_8 & \frac{2}{3}\Lambda_8 & 0 & 0 & -4\Lambda_7 & 4\Lambda_7 & 0
\end{pmatrix} \begin{pmatrix}
(k_{eff})_{XXX} - (\tilde{k}_{eff})_{ZZZ} \\
(k_{eff})_{YYY} - (\tilde{k}_{eff})_{ZZZ} \\
(k_{eff})_{XXY} - (\tilde{k}_{eff})_{ZZZ} \\
(k_{eff})_{XXZ} - (\tilde{k}_{eff})_{ZZZ} \\
(k_{eff})_{XYZ} - (\tilde{k}_{eff})_{ZZZ} \\
(k_{eff})_{XYY} \\
(k_{eff})_{XYX} \\
(k_{eff})_{XYZ}
\end{pmatrix}
\]

\[(27)\]
for odd harmonics. Any experimental design for searching LIV should make $\Lambda_i$ as large as possible.

V. EXPERIMENTAL DESIGN WITH PERIODIC STRIPED GEOMETRY

The most effective geometry for detecting Yukawa-type non-Newtonian gravity is plane-on-plane. This allows one to place the most matter within a given minimum separation between the test and source masses, and makes it practical to place a conducting membrane between the test and source masses for an electrostatic shield. However, the plane-on-plane configuration is not optimal for testing LIV. The LIV force is suppressed for parallel plate geometry, and vanishes altogether in the limit where one plate has infinite area [9]. A more effective geometry for testing LIV is realized with the striped geometry in the $z$ direction.

The inverse-cubic behavior of the potential in Eq. (1) leads to an inverse-quartic force between two point masses. The rapid growth of the force at short distances suggests that the best sensitivities to LIV can be achieved in short-range experiments, which measure the deviation from the Newton gravitational force between two masses. On the other hand, gravitational signals at sufficiently short distances are expected to be overwhelmed by electrostatic, acoustic and Casimir force backgrounds. In the HUST 2011 short-range experiment, which explored the distance range between 0.4 mm and 1.0 mm, these effects were controlled to below the level of the Newtonian background and instrumental thermal noise. Therefore, we base our design for searching the LIV effect on the Newtonian background.

A. Test masses and torsion pendulum

Generally, a high sensitivity test of LIV at millimeter ranges requires that the thickness of the test and source masses, the gap between them, and the source mass amplitude be on the same order of centimeters. The shape of the masses should adopt the striped geometry as shown in Fig. 1 to increase the LIV signal. The width of each strip should also be of the same order of millimeters. The general design is based on the I-shaped pendulum used in our previous work [20, 21]. The pendulum, shown in Fig. 2, consists of three rectangular glass blocks. Two blocks, each $23 \times 19.8 \times 19.8$ mm, support the test masses at each end, and are joined by the third block measuring $64 \times 11 \times 18$ mm. Ten pure tungsten strips, each measuring $1.3 \times 19.8 \times 2.2$ mm, are attached to the vertical surface of each end block in a parallel arrangement with equal spacing, to serve as test masses ($W_{t1}$ and $W_{t2}$). To keep the surface of the test masses flat, glass strips of thickness $1.3 \times 19.8 \times 2.2$ mm, are inset in the gaps between the tungsten strips. The pendulum; with a total mass of about 70 g is suspended by a 25 $\mu$m diameter tungsten fiber.

B. Source masses and translation stage

The source mass platform, facing to the pendulum, is also designed with the same I-shaped structure. Two source masses ($W_{s1}$ and $W_{s2}$) with the same sizes as the test masses ($W_{t1}$ and $W_{t2}$), are adhered to the two end glass blocks with dimensions $19.8 \times 19.8 \times 19.8$ mm. In our design, the source masses are opposite to the test masses, and all of them have the same shape. Therefore, there are two sets of the face-to-face structure for the masses, which can be denoted by the left set ($W_{t1}$, $W_{s1}$) and the right set ($W_{t2}$, $W_{s2}$), respectively. In this design, we...
shown in Fig. 3, and \( W_s \) of the strip (1.1 mm in negative z-axis, or shifting \( -\pi/2 \) in phase).

FIG. 3: (color online) Relative positions for test mass \( W_t \) and source mass \( W_s \) in \( x-z \) plane. The position of \( W_s \) is shifted up half of the width of the strip (\( +\pi/2 \) in phase).

The attempt to increase the LIV signal and meanwhile decrease the Newton force signal. After a comprehensive consideration, we came up with the following design: in the both two sets, the positions of the test masses (\( W_t \) and \( W_s \)) in the left set is shifted up for \( a \) of the width of the strip (shifting for a phase \( A \)), while the source mass (\( W_s \)) in right set is shifted down for \( b \) of the width of the strip (shifting for a phase \( B \)). Note that when the total shift for the source masses is kept \( a + b = 1 \) (\( |A| = |B| = \pi/2 \)), a doubled LIV torque on the pendulum can be produced, since the LIV force acting on \( W_t \) due to \( W_s \) is approximately in the opposite direction to the force acting on \( W_t \) due to \( W_s \). However, to compensate the Newtonian force well, we finally make a symmetric design, choosing \( |A| = |B| = \pi/2 \), i.e. \( W_s \) is shifted up half of the width of the strip (1.1 mm in positive z-axis, or shifting \( +\pi/2 \)) as shown in Fig. 3, and \( W_s \) is shifted down half of the width of the strip (1.1 mm in negative z-axis, or shifting \( -\pi/2 \)) as shown in Fig. 4. In this design, the Newtonian force between \( W_t \) and \( W_s \) was strictly counteracted by interaction between \( W_t \) and \( W_s \). This \( " \)anti-symmetric\( " \) design strongly suppresses the Newtonian gravitational interaction, while the striped geometry enhances the signal of LIV.

The beam which supports the source and counter mass is symmetrically supported by a glass block, which is mounted on a motor-driven translation stage. The measured signal in the experiment is usually the variation of the torque as the gap between test mass and source mass changes. The experiment will monitor the interaction between test mass and source mass for separations ranging from 0.4 to 1.0 mm.

C. Expected signal

The experimental design leads to a null test of the expected LIV signal. In the experiment, the average gap is set to 0.7 mm, and the motor translation stage is operated continuously with amplitude 0.3 mm at frequency \( f_s \). Meanwhile, a copper cylinder mounted on an external turntable is rotated synchronously for gravitational calibration at frequency \( f_c \). The motion of the pendulum is controlled by using a proportional-integral-differential feedback system. In this case, the tungsten fiber is always untwisted during the measurement; the feedback voltage reflects the changes of all effective torques experienced by the pendulum. The measured LIV torque would be

\[
\tau_{\text{measured}}(T) = \tau_{\text{LV}}(T) \cos(2\pi f_s T + \varphi),
\]

where \( \varphi \) is the initial phase of the separation modulation, which can be determined according to the operation procedure in the experiment. It should be noted that the modulation frequency \( f_s \) can be set far larger than sidereal frequency, such as \( f_s = 1/500s \). Then in data processing, \( \tau_{\text{LV}}(T) \) can be taken to be constant in each modulation period \( T_s \).

Using Eqs. (26)-(28), \( \tau_{\text{LV}}(T) \) can be further expressed as a Fourier series in the sidereal time \( T \), and the relations between the nine Fourier amplitudes and the \( (\delta_\text{eff})_{JKLM} \) are described by the 14 coefficients \( \Lambda_j \) for \( j = 1, 2, \ldots, 14 \) in Eq. (25). Although the calculation of \( \Lambda_j \) between two rectangular plates needs a 6-dimensional integral, the 3-dimensional integral for one plate and a single point can be carried out analytically. The result is derived in Appendix A. Calculation of the remaining 3D integral for \( \Lambda_j \) between two finite rectangular plates is carried out numerically. We perform the integration over the complete experimental design in Fig. 2, including the glass blocks, to obtain values for each \( \Lambda_j \) with \( j = 1, 2, \ldots, 14 \). Fig. 5 shows results for the largest \( \Lambda_j \) for each of the signal harmonics (including DC), plotted as a function of the gap between the test masses and source masses. In the plot, the \( \Lambda_j \) are shown relative to their value at the assumed minimum gap (0.4 mm). We note that \( \Lambda_2, \Lambda_4, \Lambda_7 \) are the largest terms for the even harmonics, and \( \Lambda_{11}, \Lambda_{13} \) are the largest for the odd harmonics.

The sinusoidal modulation of the source mass will re-
The total expected LIV torque acting on the closed-loop pendulum is

\[ \tau_{LV}(T) = \sum_{j=1}^{2} \Delta \Lambda_j \bar{k}_j + \sum_{j=3}^{6} \Delta \Lambda_j \bar{k}_j \cos(2\omega T) + \sum_{j=7}^{8} \Delta \Lambda_j \bar{k}_j \cos(4\omega T) + \sum_{j=9}^{12} \Delta \Lambda_j \bar{k}_j \cos(\omega T) + \sum_{j=13}^{14} \Delta \Lambda_j \bar{k}_j \cos(3\omega T) \]

\[ + \left( -\frac{1}{2} \Delta \Lambda_1 \bar{k}_3 - \frac{1}{2} \Delta \Lambda_2 \bar{k}_4 + 2 \Delta \Lambda_3 \bar{k}_5 + 2 \Delta \Lambda_4 \bar{k}_6 \right) \sin(2\omega T) + \left( \frac{1}{4} \Delta \Lambda_5 \bar{k}_7 - 4 \Delta \Lambda_6 \bar{k}_8 \right) \sin(4\omega T) + \left( -\Delta \Lambda_8 \bar{k}_9 + \Delta \Lambda_9 \bar{k}_{10} - \Delta \Lambda_{12} \bar{k}_{11} + \Delta \Lambda_{11} \bar{k}_{12} \right) \sin(\omega T) + \left( \Delta \Lambda_{14} \bar{k}_{13} - \Delta \Lambda_{13} \bar{k}_{14} \right) \sin(3\omega T) \]

(31)

with amplitudes \( \Delta \Lambda_j \) listed in third column of Table I. According to FIG. 5, the transfer coefficients \( \Lambda_j \) vary with the gap \( d \) between the test mass and source mass, especially changing quickly with decreasing \( d \) when smaller than 0.8 mm. The experiment is undertaken by implementing a dynamic modulated measurement of the gap distance, thus the value of \( d \) is designed to be in the sensitive range, between 0.4 mm to 1.0 mm, which is also the order of the strip width (1.3mm).

For comparison, we also list the value of \( \Delta \Lambda_j \) in our previous short-range experiment HUST-2011 in the fourth column of Table I, which used planar geometry to search for Yukawa-type non-Newton gravity, with the ratio illustrating the relative suppression of the LIV signal. The transfer coefficients \( \Delta \Lambda_j \) for the new experimental design have largely improved. As shown in the fifth column of Table I, for the constant term \( C_0 \), the transfer coefficients include \( \Delta \Lambda_1 \) with \( j = 1, 2 \). The ratio of \( \sqrt{\Delta \Lambda_1^2 + \Delta \Lambda_2^2} \) in this design to that of HUST-2011 is about 65, which means signal for LIV for \( \bar{k}_1 \) and \( \bar{k}_2 \) can improve 65 times. For the second harmonic frequency terms \( C_2 \) and \( S_2 \), the transfer coefficients include \( \Delta \Lambda_j \) with \( j = 3, 4, 5, 6 \). The ratio of \( \sqrt{\Delta \Lambda_3^2 + \Delta \Lambda_4^2 + \Delta \Lambda_5^2 + \Delta \Lambda_6^2} \) in this design to that of HUST-2011 is about 19, which means signal of LIV for \( \bar{k}_3 \), \( \bar{k}_4 \), \( \bar{k}_5 \) and \( \bar{k}_6 \) can improve 19 times. Similarly, the ratio of \( |\Delta \Lambda_j| \) with \( j = 7, 8 \) for fourth harmonic frequency terms

\[ \Delta \Lambda_j \approx \frac{1}{2} |\Lambda_j(d_{\text{min}}) - \Lambda_j(d_{\text{max}})|. \]

| Statistical error (thermal noise)           | 0.4                            |
| Total                                       | 3.8                            |

is about 1.4. The ratio of $|\Delta \lambda_j|$ with $j = 9, 10, 11, 12$ is about 15. And the ratio of $|\Delta \lambda_j|$ with $j = 13, 14$ is about 40.

\[
\tau_{\text{min}}(\omega) = \sqrt{\frac{4k_B T I \omega_0^2}{I \omega_0 Q}}. \tag{33}
\]

Taking integration time $t \approx 10$ days, $I \omega_0^2 \approx 1 \times 10^{-8}$ Nm/rad, $Q \approx 1500$, we get $\tau_{\text{min}} \approx 0.4 \times 10^{-16}$ Nm at room temperature, this represents the uncertainty of $C_0$. $C_m$ and $S_m$ introduced by thermal noise.

Although the “anti-symmetric” design based on opposite phases can effectively eliminate the Newtonian torque, there are potentially many errors in the machining and aligning of the masses. In general, the pendulum and source masses can be machined with dimensional tolerances on the order of microns, though errors even at this level can produce non-negligible Newtonian effects. However, Newtonian torque is independent of sidereal time $T$ and only affects the constant term $C_0$. Table II lists the main metrology uncertainties used in the numerical model, which translate into the uncertainty of $C_0$. The largest uncertainty comes from the alignment of the height of the source mass system relative to the height of the torsion pendulum. We assume that the position alignment accuracy along both horizontal and vertical directions is 4 microns. Other errors, such as test mass and source mass width and thickness, are also important. The total metrology error is estimated to be $3.8 \times 10^{-16}$ Nm. Thus, compared with the statistical error (thermal noise), the uncertainty of $C_0$ is dominated by the systematic error.

In the short-range experiments, the diurnal fluctuations mainly include the temperature, pressure and electrostatic background fluctuations. These fluctuations affect the torque mainly in two ways: 1) they change the dimensions and relative positions of the pendulum and the attractor, which lead to a variation of the amplitude of the $f_s$ Newtonian torque, consequently contributing the uncertainties to the torque amplitude modes $C_m$ and $S_m$. Usually, these influences are so small, which will be discussed simply in the following paragraphs. 2) they change the equilibrium position of the torsion balance, leading directly to a torque variation through the corresponding temperature/pressure/electrostatic-to-torque coefficient. Since we focus on the sidereal Lorentz variation signal, which is modulated to the frequency $f_s$, the relevant concern therefore is the diurnal variation of the amplitude of the $f_s$ torque signal and its harmonics. Based on the typically related data monitors in our laboratory, we can give a rough upper limit to the errors of the torque amplitude modes $C_m$ and $S_m$ after extracting the temperature/pressure/electrostatic amplitude fluctuation of the $f_s$ torque signal. We will analyze the corresponding systematic errors respectively as below:

For the temperature fluctuation, the largest variation of the geometric parameters due to the temperature fluctuation is the relative height between the pendulum and the attractor, which can be taken to be 0.04 $\mu$m for
TABLE III: Errors on the $C_m$ and $S_m$ amplitude in the design with periodic strips, which include the diurnal fluctuations and the statistical error (thermal noise).

| Source                           | Error in $C_m$ and $S_m$ $(10^{-16}\text{Nm})$ |
|----------------------------------|-------------------------------------------------|
| Temperature fluctuation          | $< 0.07$                                        |
| Pressure fluctuations            | $< 0.001$                                       |
| Electrostatic fluctuations       | $< 0.20$                                        |
| Statistical error (thermal noise)| $\sim 0.40$                                     |
| Total                            | $< 0.45$                                        |

the semidiurnal variation \(\tau_{12}\), resulting in a variation of $< 0.03 \times 10^{-16} \text{Nm}$ in the amplitude of the \(f_s\) Newtonian torque; for typical parameter values, the amplitude fluctuation of the \(f_s\) temperature signal can be assumed as $3 \mu K$, resulting in a \(f_s\) torque noise of $< 0.07 \times 10^{-16} \text{Nm}$ at the $2\sigma$ level with the temperature-to-torque coefficient of $1.1 \times 10^{-12} \text{Nm/K}$.

For the pressure and electrostatic fluctuations, both of them influence the dimensions and relative positions of the pendulum and the attractor slightly, which usually can be negligible. Based on the data in our previous experiments, the amplitude fluctuation of the \(f_s\) press signal can be taken as 0.004 mbar, resulting in a \(f_s\) torque noise of $< 0.001 \times 10^{-16} \text{Nm}$ at the $2\sigma$ level through a pressure-to-torque coefficient of $1.8 \times 10^{-17} \text{Nm/mbar}$; For the electrostatic fluctuation, it is usually regarded as a main error sources in short-range experiments \(\tau_{12}\). To minimize the electrostatic force between the pendulum and the source masses, we can insert two stretched beryllium-copper membranes between the test masses and source masses to prevent direct electrostatic coupling. The pendulum and the source mass beams can be entirely gold plated and commonly grounded to prevent contact potentials. Furthermore, the average residual differential potential between the pendulum and the two membranes can be measured and then compensated individually in each experimental cycle. At millimeter ranges, the electrostatic background is usually smaller than thermal noise. For typical parameter values, the amplitude fluctuation of the \(f_s\) electrostatic variation can be reasonably assumed as $2 \times 10^{-7} \text{V}$ \(\tau_{12}\), resulting in a \(f_s\) torque noise of $< 0.20 \times 10^{-16} \text{Nm}$ at the $2\sigma$ level through a simple calculation.

From the above analysis, compared with the statistical errors (thermal noise about $0.40 \times 10^{-16} \text{Nm}$), the systematic errors discussed above are small (see TABLE III). Therefore, thermal noise sets a fundamental limit to the sensitivity of the torque in $C_m$ and $S_m$, i.e. the uncertainties for the modes $C_m$ and $S_m$ can be treated as the same size and dominated by statistical errors in experiment, while the uncertainty of $C_0$ is dominated by the systematic error.

The above design with striped geometry has the periodic structure in the \(z\) direction. A similar design has the same periodic structure of the source and test masses in the \(y\) direction. The design is shown in Fig. 6. As shown in Fig. 7, the position of source Ws1 is shifted to the left of detector Wt1 by half the width of a strip; the position of source Ws2 is shifted to the right of detector Wt2 by the same amount. Compared to be LIV force acting on Wt1 due to Ws1, the force acting on Wt2 due to Ws2 is approximately in the opposite direction, so the total LIV torque on the pendulum is doubled.

Assuming all other conditions of this design to be equivalent to the design in Sec. V, the corresponding values of the transfer coefficients $\Lambda$ are shown in Table IV. Only six terms, $\Delta \lambda_j$ with $j = 5, 6, 8, 10, 12, 14$, are nonzero. This is as expected from Eq. (11), in which only the corresponding terms terms contain odd powers of $y$. Compared with Table I, the LIV signal for the harmonic
frequency terms in the design with periodic structure in y axis direction is stronger than that for periodic structure in z axis direction. However, a weakness is that it is insensitive to constant terms $C_0$, due to the bilateral symmetry of the sources mass.

It is arguable that the design with periodicity in the z direction is preferable (Fig. 2), which is sensitive to symmetry of the sources mass.

| TABLE IV: Transfer coefficients $\Delta\Lambda_j$ for the LIV in another design. | Transfer coefficients | This design  | Ratio of $|\Delta\Lambda_j|$ to that in HUST-2011 |

| 1 | $\Delta\Lambda_{12}$ | -72.5 | |
| 3 | $\Delta\Lambda_{13}$ | 0 | 53 |
| 3 | $\Delta\Lambda_{14}$ | 58.9 | |

Torsion pendulum experiments that test short-range gravity are sensitive to the Lorentz invariance violations involving quadratic couplings of Riemann curvature. The Lorentz invariance violation torque includes 14 transfer coefficients $\Delta\Lambda_j$ with $j = 1, 2 \cdots 14$, which connect with the 14 measurable coefficients $(k_{eff})_{JKLM}$. We decomposed the space $(k_{eff})_{JKLM}$ (14 dimensions) into 5 sub-spaces, separating the different harmonics of the Lorentz invariance violation signal and making different harmonic violation signals correspond to different subspaces. From this point of view we optimise our system in the millimeter range, where anticipated backgrounds are small. After a comprehensive consideration of the form of the LIV force between finite plates, we conclude that a design with striped test masses with periodic density variation will significantly enhance the LIV signal in a torsion pendulum experiment. A geometry with periodic structure in the z direction will have sensitivity to all measurable coefficients of Lorentz violation. An asymmetric design in which the test masses on each side of the pendulum are shifted in opposite directions relative to the source masses, can effectively eliminate the Newtonian gravitational interaction to first order, while greatly enhancing the effects of Lorentz violation. We expect this new design can improve the current constraints on the Lorentz invariance violating coefficients by more than an order of magnitude.

Appendix: The analytic expression of Lorentz violation gravitational field for a rectangular plate model

The calculation of the Lorentz violation force between two rectangular plates needs a 6-dimension integral. The 3-dimensional integral for one plate can be analytically carried out. In this Appendix, we will show that the Lorentz violation gravitational field of a rectangular plate has an analytic expression. In order to simplify the derivation process, we only focus on one term, such as \((\vec{k}_{\text{eff}})_{xxyy}\) term in SME lab frame as an example. For the other terms, the derivation can be made in a similar way.

The perturbative potential of a point mass \(m\) is given by

\[
U_{LV,xxyy}(\vec{r}) = -\frac{Gm}{r^3} \left(3-9\frac{x^2+y^2}{r^2}+45\frac{z^2}{r^4}\right)(\vec{k}_{\text{eff}})_{xxyy}
\]

at position \((x,y,z)\) due to the \((\vec{k}_{\text{eff}})_{xxyy}\) term. To calculate the perturbative potential of a rectangular plate, we perform a 3-dimensional integral over the volume of the plate.

We assume that the density of the rectangular plate is \(\rho\) and the dimensions are \(2a \times 2b \times 2c\) (in the \(x, y\) and \(z\) directions, respectively) in SME lab frame. We also adopt the plate coordinate system with the origin at the center of the plate. Supposing a unit point mass is at the position \((x,y,z)\) in the plate frame (equal and parallel to the SME lab frame but with different origin), the Lorentz violation gravitational interaction between the rectangular plate and the point mass is given by

\[
\begin{align*}
U_{LV,xxyy}(x, y, z) &= -\int_{x-a}^{x+a} \int_{y-b}^{y+b} \int_{z-c}^{z+c} G\rho \left[3 - 9\frac{x^2+y^2}{x_1^2+y_1^2+z_1^2} + 45\frac{z^2}{x_1^2+y_1^2+z_1^2}\right] (\vec{k}_{\text{eff}})_{xxyy} \, dx_1 \, dy_1 \, dz_1 \\
&= -\left(\vec{k}_{\text{eff}}\right)_{xxyy} G\rho \int_{x-a}^{x+a} \int_{y-b}^{y+b} \left[3 - 9\frac{x^2+y^2}{x_1^2+y_1^2+(z+c)^2} + 45\frac{z^2}{x_1^2+y_1^2+(z+c)^2}\right] \, dx_1 \, dy_1 \\
&\quad + (\vec{k}_{\text{eff}})_{xxyy} G\rho \int_{x-a}^{x+a} \int_{y-b}^{y+b} \left[3 - 9\frac{x^2+y^2}{x_1^2+y_1^2+(z-c)^2} + 45\frac{z^2}{x_1^2+y_1^2+(z-c)^2}\right] \, dx_1 \, dy_1
\end{align*}
\]

Taking the derivative with respect to \(z\), we obtain the Lorentz violation gravitational field in \(z\) axis direction

\[
a^z(a, b, c; x, y, z) \equiv \partial_z U(x, y, z)
\]

\[
= -\left(\vec{k}_{\text{eff}}\right)_{xxyy} G\rho \int_{x-a}^{x+a} \int_{y-b}^{y+b} \left[3 - 9\frac{x^2+y^2}{x_1^2+y_1^2+(z+c)^2} + 45\frac{z^2}{x_1^2+y_1^2+(z+c)^2}\right] \, dx_1 \, dy_1 \\
\quad + (\vec{k}_{\text{eff}})_{xxyy} G\rho \int_{x-a}^{x+a} \int_{y-b}^{y+b} \left[3 - 9\frac{x^2+y^2}{x_1^2+y_1^2+(z-c)^2} + 45\frac{z^2}{x_1^2+y_1^2+(z-c)^2}\right] \, dx_1 \, dy_1
\]

The integral can be carried out resulting in an analytical expression. After defining the functions

\[
f(x, y, z) \equiv \int_{x-a}^{x+a} \int_{y-b}^{y+b} \frac{1}{(x^2+y^2+z^2)^{3/2}} \, dx \, dy = \frac{1}{z} \arctan \frac{xy}{z \sqrt{x^2+y^2+z^2}}
\]

\[ f_{xx}(x, y, z) = \int \int \frac{1}{(x^2 + y^2 + z^2)^{3/2}} x^2 \frac{1}{x^2 + y^2 + z^2} dxdy = \frac{1}{3} \left[ -\frac{xy}{(x^2 + z^2)^{3/2}} + \frac{1}{z} \arctan \frac{xy}{z(x^2 + y^2 + z^2)} \right] \] (A5)

\[ f_{yy}(x, y, z) = \int \int \frac{1}{(x^2 + y^2 + z^2)^{3/2}} y^2 \frac{1}{x^2 + y^2 + z^2} dxdy = \frac{1}{3} \left[ -\frac{xy}{(y^2 + z^2)^{3/2}} + \frac{1}{z} \arctan \frac{xy}{z(x^2 + y^2 + z^2)} \right] \] (A6)

\[ f_{xxyy}(x, y, z) = \int \int \frac{1}{(x^2 + y^2 + z^2)^{3/2}} x^2 y^2 \frac{1}{x^2 + y^2 + z^2} dxdy = \frac{1}{15} \left[ -\frac{xy(x^4 + (y^2 + z^2)^2 + x^2(y^2 + z^2)^2)}{(x^2 + z^2)(y^2 + z^2)(x^2 + y^2 + z^2)^{3/2}} + \frac{1}{z} \arctan \frac{xy}{z(x^2 + y^2 + z^2)} \right] \] (A7)

we obtain the analytic expression of the gravitational field in \( z \)-axis direction

\[ a^z(a, b, c; x, y, z) = -G\rho(k_{eff}) f_{xxyy}(x, y, z) \bigg|_{x=x+a, y=y+b, z=z-c} \bigg|_{x=x-a, y=y-b, z=z-c} \] (A8)

with

\[ F_{xxyy}^z(x, y, z) = 3f(x, y, z) - 9f_{xx}(x, y, z) - 9f_{yy}(x, y, z) + 45f_{xxyy}(x, y, z) \] (A9)

The gravitational field in \( x \)-axis or \( y \)-axis direction can be derived in a similar way.
