ON ORIENTED m-SEMIREGULAR REPRESENTATIONS OF FINITE GROUPS ABOUT VALENCY TWO

JIA-LI DU, YOUNG SOO KWON, AND DA-WEI YANG*

Abstract. Given a group $G$, an $m$-Cayley digraph $\Gamma$ over $G$ is a digraph that has a group of automorphisms isomorphic to $G$ acting semiregularly on the vertex set with $m$ orbits. We say that $G$ admits an oriented $m$-semiregular representation (OmSR for short), if there exists a regular $m$-Cayley digraph $\Gamma$ over $G$ such that $\Gamma$ is oriented and its automorphism group is isomorphic to $G$. In particular, O1SR is also named as ORR. Verret and Xia gave a classification of finite simple groups admitting an ORR of valency two in [Ars Math. Contemp. 22 (2022), #P1.07]. Let $m \geq 2$ be an integer. In this paper, we show that all finite groups generated by at most two elements admit an OmSR of valency two except four groups of small orders. Consequently, a classification of finite simple groups admitting an OmSR of valency two is obtained.

Keywords: Semiregular group, regular representation, $m$-Cayley digraph, oriented $m$-semiregular representation.

2010 Mathematics Subject Classification: 05C25, 20B25.

1. Introduction

By a digraph $\Gamma$, we mean an ordered pair $(V, A)$ where the vertex set $V$ is a non-empty set and the arc set $A$ is a binary relation on $V$, that is, $A \subseteq V \times V$. The elements of $V$ and $A$ are called vertices and arcs of $\Gamma$, respectively. For simplicity, we write $V(\Gamma) := V$ and $A(\Gamma) := A$. The digraph $\Gamma$ is a graph if the binary relation $A$ is symmetric, that is, $A = \{(v, u) \mid (u, v) \in A\}$. A digraph is called regular if each vertex has the same in- and out-valency. For a vertex $u \in V(\Gamma)$, let $\Gamma^+(u)$ be the set of vertices $v$ such that $(u, v) \in A(\Gamma)$. Throughout this paper, all digraphs are regular, and all digraphs and groups are finite.

Let $\Gamma$ be a digraph, and let $\omega \in V(\Gamma)$. An automorphism of $\Gamma$ is a permutation $\sigma$ of $V(\Gamma)$ fixing $A(\Gamma)$ setwise, that is, $(x^\sigma, y^\sigma) \in A(\Gamma)$ if and only if $(x, y) \in A(\Gamma)$. The set of all automorphisms of $\Gamma$, with the operation of composition, is the full automorphism group of $\Gamma$, denoted by $\text{Aut}(\Gamma)$. For a subgroup $G$ of $\text{Aut}(\Gamma)$, denote by $G_\omega$ the stabilizer of $\omega$ in $G$, that is, the subgroup of $G$ fixing $\omega$. We say that $G$ is semiregular on $V(\Gamma)$ if $G_\omega = 1$ for every $\omega \in V(\Gamma)$, and regular if it is semiregular and transitive.

Let $G$ be a group, and let $S$ be a subset of $G$. The Cayley digraph $\Gamma := \text{Cay}(G, S)$ is the digraph with $V(\Gamma) := G$ and $A(\Gamma) := \{(g, sg) \mid g \in G, s \in S\}$. In particular, $\Gamma$ is a Cayley graph if and only if $S = S^{-1}$. The right regular representation $R(G)$ of $G$ gives rise to an embedding of $G$ into $\text{Aut}(\Gamma)$, that is, $R(G)$ is a subgroup of $\text{Aut}(\Gamma)$. If $\text{Aut}(\Gamma)$ actually coincides with $R(G)$, then the (di)graph $\Gamma$ is said to be a (di)graphical regular representation over $G$, and this is usually abbreviated to GRR (or DRR). GRRs (or DRRs) offer a natural way to represent groups geometrically and combinatorially as groups of automorphisms of (di)graphs [13]. The problem that determining the finite groups admitting a GRR or DRR has a long history. The complete classification of finite groups admitting a DRR has been given by Babai [1], and it was shown that except for five small groups, every group admits a DRR. Clearly, if a group $G$ admits a GRR, then $G$ admits a DRR, however the converse is not true. The GRR turned out to be much more difficult to handle and, after a long series of partial results by various authors [8, 9, 10, 11, 15, 16, 19], the classification was completed by Godsil in [6]. Once the classifications of DRRs and GRRs were completed, researchers proposed and investigated various natural generalizations. In the following paragraphs, we mainly introduce some background about oriented $m$-semiregular representation; one may see [13, 14, 17] for the introduction of some other generalizations.

Oriented regular representation, i.e. ORR. A digraph is oriented if it does not have both oppositely directed arcs between any pairs of vertices. An oriented Cayley digraph is in some sense a proper digraph. More formally, it is a Cayley digraph $\text{Cay}(G, S)$ whose connection set $S$ has the property that $S \cap S^{-1} = \emptyset$. Equivalently, in graph-theoretic terms, it is a digraph with no digons, see [13]. We say that a group $G$ admits an oriented regular representation (ORR for short) if there exists an oriented Cayley digraph $\Gamma := \text{Cay}(G, S)$ over $G$ such that $\text{Aut}(\Gamma) = R(G)$. In [1] Problem 2.7, Babai asked which groups admit an ORR, and this problem was finally settled by Morris and Spiga in three papers [13, 14, 17].
Oriented $m$-semiregular representation, i.e. $O\!m\!SR$. The concept of Cayley digraphs can be nicely generalized to $m$-Cayley digraphs where regular actions are replaced with semiregular actions. An $m$-Cayley (di)graph $\Gamma$ over a finite group $G$ is defined as a (di)graph which has a semiregular group of automorphisms isomorphic to $G$ with $m$ orbits on its vertex set. Actually, $1$-Cayley (di)graphs are the usual Cayley (di)graphs and, $2$-Cayley (di)graphs are also called bi-Cayley (di)graphs, see [12]. We say that a group $G$ admits a 
(di)graphical $m$-semiregular representation ($Gm\!SR$ and $Dm\!SR$, for short), if there exists a regular $m$-Cayley (di)graph $\Gamma$ over $G$ such that $\text{Aut}(\Gamma) = R(G)$, and admits an oriented $m$-semiregular representation ($O\!m\!SR$ for short), if there exists a regular $m$-Cayley digraph $\Gamma$ over $G$ such that it is oriented and $\text{Aut}(\Gamma) = R(G)$. In particular, $G\!SR$s and $D\!SR$s are the usual $G\!RR$s and $D\!RR$s, respectively. The groups admitting $Gm\!SR$s, $Dm\!SR$s or $O\!m\!SR$s for every positive integer $m$ were determined in [3, 4].

Oriented $m$-semiregular representation of prescribed valency. In contrast to unrestricted $Gm\!SR$s, $Dm\!SR$s and $O\!m\!SR$s, the classification of groups admitting $Gm\!SR$s, $Dm\!SR$s, or $O\!m\!SR$s of prescribed valency is largely open.

Since a connected graph of valency one or two is an edge or a cycle, the smallest interesting case is of valency three. The study on cubic $G\!RR$s has begun with a piece of Godsil’s work [5], which confirmed the existence of cubic $G\!RR$s of the symmetric and alternating group. Recently, lots of research has been done on finite simple groups admitting a cubic $G\!RR$. Moreover, Spiga [18] gave some sufficient conditions for a cubic Cayley graph of a non-abelian simple group to be a $G\!RR$.

For digraphs, the smallest interesting case is of valency two, as a connected digraph of valency one is just a directed cycle. Recently, Verret and Xia [21] classified simple groups admitting an $O\!1\!RR$ of cubic $G\!RR$ of the symmetric and alternating group. For example, Xia and Fang [20, 22, 23] studied some simple groups of Lie type admitting a cubic $G\!RR$. For instance, $G\!SR$s and $D\!SR$s are the usual $G\!RR$s and $D\!RR$s, respectively. The groups admitting $Gm\!SR$s, $Dm\!SR$s or $O\!m\!SR$s for every positive integer $m$ were determined in [3, 4].

Let $G$ be a finite group generated by at most two elements, and let $m \geq 2$ be an integer. Then $G$ admits no $O\!m\!SR$ of valency two if and only if one of the following occurs:

1. $m = 2$ and $G \cong \mathbb{Z}_1$, $\mathbb{Z}_2$ or $\mathbb{Z}_2^2$;
2. $3 \leq m \leq 6$ and $G \cong \mathbb{Z}_1$.

Consequently, a complete classification of simple groups admitting an $O\!m\!SR$ of valency two can be obtained.

Corollary 1.2. Let $G$ be a finite simple group, and let $m \geq 2$ be an integer. Then $G$ admits an $O\!m\!SR$ of valency two except $(m, G) = (2, \mathbb{Z}_2)$.

We can see from Theorem 1.1 that almost all finite groups generated by two elements have an $O\!m\!SR$ of valency two when $m \geq 2$. However, this is not true when $m = 1$. A counterexample is the dihedral group, one may also see [11]. Moreover, the abelian group $\mathbb{Z}_m \times \mathbb{Z}_m$ also has no $O\!RR$ of valency two, since it has an automorphism interchanging the two generators for each minimal generating set. To end this section, we would like to propose the following problem.

Problem 1.3. Classify finite groups generated by at most two elements admitting an $O\!1\!RR$ of valency two.

2. Preliminaries and notations

Let $m$ be a positive integer, and let $G$ be a group. Consistently throughout the whole paper, for not making our notation too cumbersome to use, we denote the element $(g, i)$ of the cartesian product $G \times \{0, \ldots, m-1\}$ simply by $g_i$. We often identify $\{0, \ldots, m-1\}$ with $\mathbb{Z}_m$, that is, with the integers modulo $m$.

For every $i, j \in \mathbb{Z}_m$, let $T_{i,j}$ be a subset of $G$. The $m$-Cayley digraph of $G$ with respect to $(T_{i,j} : i, j \in \mathbb{Z}_m)$ is the digraph with vertex set

$G \times \mathbb{Z}_m = \bigcup_{i \in \mathbb{Z}_m} G_i$,

where $G_i = \{g_i : g \in G\}$, and with arc set

$\bigcup_{i, j} \{(g_i, (tg)_j) : t \in T_{i,j}, g \in G\}$. 

We denote this digraph by \( \text{Cay}(G, T_{i,j} : i, j \in \mathbb{Z}_m) \).

For any given \( g \in G \), the right multiplication \( R(g) \) mapping each vertex \( x_i \in G_i \) to \( (xg)_i \in G_i \) for all \( i \in \mathbb{Z}_m \), is an automorphism of \( \Gamma \), and \( R_1(G) = \{ R(g) \mid g \in G \} \) is a semiregular group of automorphisms of \( G \) with \( G_i \) as orbits. Thus \( \{ R(g) \mid g \in G \} \) is a subgroup of Aut(\( \Gamma \)) isomorphic to \( G \).

To end this section, we give a result about the elementary abelian 2-groups admitting OmSRs of valency two, see the Remark 3.5 in [4].

**Proposition 2.1.** \( \mathbb{Z}_1 \) admits an OmSR of valency two if and only if \( m \geq 7 \), and \( \mathbb{Z}_2 \) admits an OmSR of valency two if and only if \( m \geq 3 \) with \( 1 \leq t \leq 2 \).

### 3. Proof of Theorem 1.1

This section aims to give the proof of Theorem 1.1 which will be divided into two lemmas. In our first lemma we deal with cyclic groups.

**Lemma 3.1.** Let \( G \) be a cyclic group, and let \( m \geq 2 \) be an integer. Then \( G \) has no OmSR of valency two if and only if

1. \( m = 2 \) and \( G \cong \mathbb{Z}_1 \) or \( \mathbb{Z}_2 \);
2. \( 3 \leq m \leq 6 \) and \( G \cong \mathbb{Z}_1 \).

**Proof.** By Proposition 2.1 \( \mathbb{Z}_1 \) has OmSR of valency two if and only if \( m \geq 7 \), and \( \mathbb{Z}_2 \) has OmSR of valency two if and only if \( m \geq 3 \). Now, we are in the position to consider the cyclic groups of order at least 3. Assume \( G = \langle a \rangle \), where the order \( o(a) \geq 3 \). Take \( T_{i,j} \subset G \) with \( i, j \in \mathbb{Z}_m \) as follows:

\[
T_{0,0} = \{a\}, \quad T_{i,i} = \{a^{-1}\} \quad \text{for} \quad i \neq 0;
\]
\[
T_{m-1,0} = \{a\}, \quad T_{i,i+1} = \{1\} \quad \text{for} \quad i \neq m - 1;
\]
\[
T_{i,j} = \emptyset \quad \text{otherwise}.
\]

Let \( \Gamma_m = \text{Cay}(G, T_{i,j} : i, j \in \mathbb{Z}_m) \) and \( A = \text{Aut}(\Gamma_m) \). Then \( \Gamma_m \) is an oriented \( m \)-Cayley digraph over \( G \) of valency two. Figure 1 might be of some help for understanding the structure of \( \Gamma_m \).

![Figure 1. The oriented m-Cayley graphs of valency two for cyclic groups](image)

It is easy to see that

\[
\Gamma_m^+(1_0) = \{a_0, 1_1\}, \quad \Gamma_m^+(1_{m-1}) = \{a_{m-1}^{-1}, a_0\},
\]
\[
\Gamma_m^+(1_i) = \{a_i^{-1}, 1_{i+1}\} \quad \text{for} \quad i \neq 0, m - 1.
\]

Let \( \Gamma_m^+(\Gamma_m^+(1_i)) \) be the set of out-neighbors of \( \Gamma_m^+(1_i) \). Then, we have

\[
\Gamma_2^+(\Gamma_2^+(1_0)) = \Gamma_2^+(a_0) \cup \Gamma_2^+(1_1) = \{a_0^2, a_1\} \cup \{a_1^{-1}, a_0\} = \{a_0, a_2, a_1, a_1^{-1}\};
\]
\[
\Gamma_m^+(\Gamma_m^+(1_0)) = \Gamma_m^+(a_0) \cup \Gamma_m^+(1_1) = \{a_0^2, a_1\} \cup \{a_1^{-1}, 1_2\} = \{a_0^2, a_1, a_1^{-1}, 1_2\} \quad \text{for} \quad m \geq 3;
\]
\[
\Gamma_m^+(\Gamma_m^+(1_{m-2})) = \Gamma_m^+(a_{m-2}^{-1}) \cup \Gamma_m^+(1_{m-1}) = \{a_{m-2}^{-2}, a_{m-1}^{-1}\} \cup \{a_{m-1}^{-1}, a_0\} = \{a_{m-2}^{-2}, a_{m-1}^{-1}, a_0\};
\]
\[
\Gamma_m^+(\Gamma_m^+(1_{m-1})) = \Gamma_m^+(a_{m-1}^{-1}) \cup \Gamma_m^+(a_0) = \{a_{m-2}^{-1}, 1_0\} \cup \{a_0^2, a_1\} = \{a_{m-2}^{-1}, 1_0, a_0^2, a_1\};
\]
\[
\Gamma_m^+(\Gamma_m^+(1_{1})) = \Gamma_m^+(a_1^{-1}) \cup \Gamma_m^+(1_{i+1}) = \{a_1^{-2}, a_{i+1}^{-1}\} \cup \{a_{i+1}^{-1}, 1_{i+2}\} = \{a_1^{-2}, a_{i+1}^{-1}, 1_{i+2}\} \quad \text{when} \quad i \neq 0, m - 2, m - 1.
\]

Recall that \( o(a) \geq 3 \). Then \( |\Gamma_m^+(\Gamma_m^+(1_0))| = 4 \) and \( |\Gamma_m^+(\Gamma_m^+(1_i))| = 3 \) for \( 1 \leq i \leq m - 2 \). Moreover, \( |\Gamma_m^+(\Gamma_m^+(1_{m-1}))| = |\{a_{m-2}^{-1}, 1_0, a_0^2, a_1\}| = 3 \) when \( m = 2 \) and \( o(a) = 3 \); and \( |\Gamma_m^+(\Gamma_m^+(1_{m-1}))| = 4 \) otherwise.
Now, we consider the cases $m = 2$ and $m \geq 3$ separately. Let $m = 2$. If $o(a) = 3$ or 4, by Magma [2], $Γ_2$ is an O2SR over $G$. Assume $o(a) \geq 5$. We consider the number of arcs in the induced sub-digraphs $[Γ_2^+(Γ_2^+(1_0))]$ and $[Γ_2^+(Γ_2^+(1_1))]$, respectively. Note that $Γ_2^+(Γ_2^+(1_0)) = \{a_0, a_0^2, a_1, a_1^{-1}\}$. By the definition of $Γ_2$, we have

$$Γ_2^+(a_0) = \{a_0^2, a_1\}, \quad Γ_2^+(a_0^2) = \{a_0^3, a_1^2\},$$

$$Γ_2^+(a_1) = \{1, a_0^2\}, \quad Γ_2^+(a_1^{-1}) = \{a_1^{-2}, 1_0\}.$$

Since $o(a) \geq 5$, there are exactly three arcs in the induced sub-digraph $[Γ_2^+(Γ_2^+(1_0))]$, that is, $\{a_0, a_0^2, a_1, a_1^{-1}\}$. On the other hand, since $Γ_2^+(Γ_2^+(1_1)) = \{1_0, a_0^2, a_1, a_1^{-2}\}$ and

$$Γ_2^+(1_0) = \{a_0, 1_1\}, \quad Γ_2^+(a_0^2) = \{a_0^3, a_1^2\},$$

$$Γ_2^+(a_1) = \{1, a_0^2\}, \quad Γ_2^+(a_1^{-1}) = \{a_1^{-3}, a_0\},$$

the induced sub-digraph $[Γ_2^+(Γ_2^+(1_1))]$ has only one arc, that is, $\{a_1, a_0^2\}$. Thus, $[Γ_2^+(Γ_2^+(1_0))] \nsubseteq [Γ_2^+(Γ_2^+(1_1))]$, and so $A$ fixes $G_0$ and $G_1$ setwise, respectively. Therefore, $A_{1_0}$ and $A_{1_1}$ fix $Γ_2^+(1_0) = \{a_0, 1_1\}$ and $Γ_2^+(1_1) = \{a_1^{-1}, a_0\}$ pointwise, respectively. We then conclude that $A_{1_0} = A_{1_1} = 1$ as $Γ$ is connected. Since $R(G) \leq A$ is transitive on $G_i$ with $i \in \mathbb{Z}_2$, $A$ has two orbits, and by the Frattini argument, we have $A = R(G)A_{1_0} = R(G)$. Hence $Γ_2$ is an O2SR over $G$ of valency two.

Let $m \geq 3$. Then $[Γ_m^+(Γ_m^+(1_{m-1}))] = 4$, and so both $G_0 \cup G_{m-1}$ and $Δ = \{G_i \mid 1 \leq i \leq m-2\}$ are fixed setwise by $A$. Since $Δ$ has out-neighbors in $G_{m-1}$ while has no out-neighbor in $G_0$ (see Figure 1), we have that $A$ fixes $G_0$ and $G_{m-1}$ setwise. Recall that $T_{i,i+1} = \{1\}$ and $T_{i,j} = \emptyset$ for each $1 \leq i \leq m-2$ and $j \neq i, i+1$. By considering the out-neighbors of $G_i$ in turn (see Figure 1), we notice that for each $0 \leq i \leq m-1$ (write $i+1 = 0$ when $i = m-1$), $G_i$ has out-neighbors only in $G_i$ and $G_{i+1}$, and so it is fixed by $A$ setwise. On the other hand, since

$$Γ_m^+(1_0) = \{a_0, 1_1\}, \quad Γ_m^+(1_{m-1}) = \{a_{m-1}^{-1}, a_0\}, \quad Γ_m^+(1_i) = \{a_i^{-1}, 1_{i+1}\}, \quad i \neq 0, m-1,$$

the stabilizer $A_{1_i}$ fixes $Γ_m^+(1_i)$ pointwise with $i \in \mathbb{Z}_m$, and so $A_{1_0} = 1$ as $Γ$ is connected. Again by Frattini argument, $A = R(G)A_{1_0} = R(G)$, and hence $Γ_m$ is an O$m$SR over $G$ of valency two. The proof is completed. □

Finally, we deal with non-cyclic groups generated by two elements.

**Lemma 3.2.** Let $G$ be a non-cyclic group generated by two elements, and let $m \geq 2$ be an integer. Then $G$ has an O$m$SR of out-valency two except $(m, G) = (2, \mathbb{Z}_2^2)$.

**Proof.** Let $G = \langle a, b \rangle$ with $o(a) \geq o(b) \geq 2$. Then $G = \langle a, ab \rangle$. If all of $a, b$ and $ab$ are involutions, then $G = \mathbb{Z}_2^2$, and it has an O$m$SR of valency two if and only if $m \geq 3$ by Proposition 2.1. In the following, we assume that at least one of $a, b$ and $ab$ has order at least 3. Without loss of generality, we assume $o(a) \geq 3$. In the following, we divide the proof into two cases.

**Case 1:** $G$ is abelian.

Take $T_{i,j} \subset G$ with $i, j \in \mathbb{Z}_m$ as follows:

$$T_{0,0} = \{a\}, \quad T_{i,i} = \{ab\} \quad \text{for } i \neq 0;$$

$$T_{m-1,0} = \{b\}, \quad T_{i,i+1} = \{1\} \quad \text{for } i \neq m-1;$$

$$T_{i,j} = \emptyset \quad \text{otherwise.}$$

Let $Γ_m = \text{Cay}(G, T_{i,j} : i, j \in \mathbb{Z}_m)$ and $A = \text{Aut}(Γ_m)$. Then $Γ_m$ is an oriented $m$-Cayley digraph over $G$ of valency two. Figure 2 might be of some help for understanding the structure of $Γ_m$.

![Figure 2](image)
Note that
\[ \Gamma_m^+(1_i) = \{a_0, 1_i\}, \quad \Gamma_m^+(1_{m-1}) = \{(ab)_{m-1}, b_0\}, \]
\[ \Gamma_m^+(1_i) = \{(ab)i, 1_{i+1}\} \quad \text{for } i \neq 0, m-1. \]

Similar as the proof of Lemma 3.1, we consider the set \( \Gamma_m^+(\Gamma_m^+(1_i)) \) for each \( i \in \mathbb{Z}_m \). By the definition of \( \Gamma_m \), we have
\[ \Gamma_2^+(\Gamma_2^+(1_0)) = \Gamma_2^+(a_0) \cup \Gamma_2^+(1_1) = \{a_0^2, a_1, (ab)_1, 0_1\}; \]
\[ \Gamma_m^+(\Gamma_m^+(1_0)) = \Gamma_m^+((ab)_{m-2}) \cup \Gamma_m^+(1_{m-1}) = \{(ab)_{m-2}, (ab)_{m-1}, b_0\}; \]
\[ \Gamma_m^+(\Gamma_m^+(1_{m-2})) = \Gamma_m^+((ab)_{m-2}) \cup \Gamma_m^+(1_{m-1}) = \{(ab)_{m-2}, (ab)_{m-1}, b_0\}; \]
\[ \Gamma_m^+(\Gamma_m^+(1_{m-1})) = \Gamma_m^+(1_{m-1}) \cup \Gamma_m^+(b_0) = \{(ab)_{m-1}, (ab^2)_{m-1}, b_0\}; \]
\[ \Gamma_m^+(\Gamma_m^+(1_i)) = \Gamma_m^+((ab)i) \cup \Gamma_m^+(1_{i+1}) = \{(ab)i, (ab)i+1, b_{i+1}\} \quad \text{when } i \neq 0, m-2, m-1. \]

Since \( o(b) \geq 2 \), we have \( ab^2 \neq ab \), and so \( |\Gamma_m^+(\Gamma_m^+(1_i))| = |\Gamma_m^+(\Gamma_m^+(1_{m-1}))| = 4 \) and \( |\Gamma_m^+(\Gamma_m^+(1_i))| = 3 \) for \( i \neq 0, m-1 \). It follows that \( A \) fixes \( G_0 \cup G_{m-1} \) setwise.

First, assume \( m = 2 \). Since \( G = (a, b) \), we have that \( \Gamma_m \) is a connected digraph. Let \( \Gamma'(1_i) \) be the set of vertices of distance at most 2 from \( 1_i \), that is, \( \Gamma'(1_i) = \{1_i\} \cup \Gamma_2^+(1_i) \cup \Gamma_2^+(\Gamma_2^+(1_i)) \) with \( i \in \mathbb{Z}_2 \). We consider the induced sub-digraphs \( [\Gamma'(1_0)] \) and \( [\Gamma'(1_1)] \), respectively. Note that \( \Gamma_2^+(\Gamma_2^+(1_0)) = \{a_0^2, a_1, (ab)_0\} \) and \( \Gamma_2^+(\Gamma_2^+(1_1)) = \{(ab)_1, (ab^2)_0, (ab)_0, 0_1\} \). By the definition of \( \Gamma_2 \), we have
\[ \Gamma_2^+(a_0^2) = \{a_0^3, a_1^2\}, \quad \Gamma_2^+(a_1) = \{(ab)_1, (ba)_0\}, \]
\[ \Gamma_2^+(ab)_1 = \{(ab)_1, (ba)_0\}, \quad \Gamma_2^+(b_0) = \{(ab)_0, b_1\}, \]
\[ \Gamma_2^+(ab)_1 = \{(ab)_1, (ba)_0\}, \quad \Gamma_2^+(ab)_0 = \{(ab)_0, 0_1\}, \]
\[ \Gamma_2^+(a_0^2) = \{a_0^3, a_1^2\}, \quad \Gamma_2^+(b_0) = \{(ab)_0, b_1\}. \]

One may see Figure 3 for the induced sub-digraphs \( [\Gamma'(1_0)] \) and \( [\Gamma'(1_1)] \), and obviously, \( [\Gamma'(1_0)] \neq [\Gamma'(1_1)] \). It yields that \( A \) fixes \( G_0 \) and \( G_1 \) setwise, respectively. Furthermore, the stabilizer \( A_{1_0} \) fixes \( \Gamma_2^+(1_0) = \{a_0, 1_1\} \) pointwise, while \( A_{1_1} \) fixes \( \Gamma_2^+(1_1) = \{(ab)_1, b_0\} \) pointwise. The connectivity of \( \Gamma \) forces \( A_{1_0} = A_{1_1} = 1 \). Since \( R(G) \leq A \) is transitive on \( G_i \) with \( i \in \mathbb{Z}_2 \), we have \( A = R(G)A_{1_0} = R(G) \), and hence \( \Gamma_2 \) is an O2SR over \( G \) of valency two.

![Figure 3](image.png)

**Figure 3.** The induced sub-digraphs \([\Gamma'(1_0)]\) and \([\Gamma'(1_1)]\)

Next, let \( m \geq 3 \). Then \( A \) fixes both \( G_0 \cup G_{m-1} \) and \( \Delta = \{G_i \mid 1 \leq i \leq m-2\} \) setwise. Since \( \Delta \) has out-neighbors in \( G_{m-1} \) but no out-neighbor in \( G_0 \), we conclude that \( A \) fixes \( G_0 \) and \( G_{m-1} \) setwise. Recalling that \( T_{i+1} = \{1\} \) and \( T_{i,j} = \emptyset \) for each \( 1 \leq i \leq m-2 \) and \( j \neq i, i+1 \) (see Figure 2), we can conclude that \( A \) fixes \( G_i \) setwise for each \( 1 \leq i \leq m-2 \). On the other hand, since
\[ \Gamma_m^+(1_0) = \{a_0, 1_1\}, \quad \Gamma_m^+(1_{m-1}) = \{(ab)_{m-1}, b_0\}, \quad \Gamma_m^+(1_i) = \{(ab)i, 1_{i+1}\}, \quad i \neq m-1, \]
we have \( A_{1_0} \) fixes \( \Gamma_m^+(1_i) \) pointwise, and so \( A_{1_0} = A_{1_1} = 1 \) as \( \Gamma \) is connected. Since \( R(G) \leq A \) is transitive on \( G_i \) with \( i \in \mathbb{Z}_m \), we conclude that \( A = R(G)A_{1_0} = R(G) \) and \( \Gamma_m \) is an OmSR over \( G \) of valency two.
Case 2: $G$ is non-abelian.

Take $T_{i,j} \subset G$ with $i, j \in \mathbb{Z}_m$ as follows:

$$
T_{i,i} = \{a\} \quad \text{for } i \in \mathbb{Z}_m;
$$
$$
T_{m-1,0} = \{b\}, \quad T_{i,i+1} = \{1\} \quad \text{for } i \neq m - 1;
$$
$$
T_{i,j} = \emptyset \quad \text{otherwise}.
$$

Let $\Gamma_m = \text{Cay}(G, T_{i,j} : i, j \in \mathbb{Z}_m)$ and $A = \text{Aut}(\Gamma_m)$. Then $\Gamma_m$ is an oriented $m$-Cayley digraph over $G$ of valency two. Figure 4 might be of some help for understanding the structure of $\Gamma_m$.

Similarly, we consider $\Gamma_m^+(\Gamma_m^+(1_i))$, the set of out-neighbors of $\Gamma_m^+(1_i)$. Since

$$
\Gamma_m^+(1_m-1) = \{a_{m-1}, b_0\}, \quad \Gamma_m^+(1_i) = \{a_i, 1_{i+1}\} \quad \text{for } i \neq m - 1,
$$

we have

$$
\Gamma_m^+(\Gamma_m^+(1_m-2)) = \Gamma_m^+(a_{m-2}) \cup \Gamma_m^+(1_m-1) = \{a_{m-2}, a_{m-1}\} \cup \{a_{m-1}, b_0\} = \{a_{m-2}, a_{m-1}, b_0\},
$$

$$
\Gamma_m^+(\Gamma_m^+(1_m-1)) = \Gamma_m^+(a_{m-1}) \cup \Gamma_m^+(b_0) = \{a_{m-1}, (ba)_0\} \cup \{(ab)_0, b_1\} = \{a_{m-1}, (ab)_0, (ba)_0, b_1\},
$$

$$
\Gamma_m^+(\Gamma_m^+(1_i)) = \Gamma_m^+(a_i) \cup \Gamma_m^+(1_{i+1}) = \{a_i^2, a_{i+1}\} \cup \{a_{i+1}, 1_{i+2}\} = \{a_i^2, a_{i+1}, 1_{i+2}\} \quad \text{when } i \neq 0, m - 2, m - 1.
$$

Since $(ab)_0 \neq (ba)_0$ because $G$ is non-abelian, $|\Gamma_m^+(\Gamma_m^+(1_m-1))| = 4$ and $|\Gamma_m^+(\Gamma_m^+(1_i))| = 3$ for each $i \neq m - 1$. Therefore, $A$ fixes $G_{m-1}$ setwise. Since $G_i$ only has out-neighbors in $G_{i+1}$ for each $0 \leq i < m - 1$ (write $i + 1 = 0$ when $i = m - 1$), it is fixed by $A$ setwise. Recall that $\Gamma_m^+(1_m-1) = \{a_{m-1}, b_0\}$ and $\Gamma_m^+(1_i) = \{a_i, 1_{i+1}\}$ for each $i \neq m - 1$. Thus, $A_1$ fixes $\Gamma_m^+(1_i)$ pointwise, and so $A_1a = 1$ as $\Gamma$ is connected. Since $R(G) \leq A$ is transitive on $G_i$ with $i \in \mathbb{Z}_m$, we have $A = R(G)A_{1_0} = R(G)$ and hence $\Gamma_m$ is an OmSR over $G$ of valency two. The proof is completed.
