The Fate of R-Parity

Pavel Fileviez Pérez, Sogee Spinner

(Dated: May 28, 2010)

The possible origin of the R-parity violating interactions in the minimal supersymmetric standard model and its connection to the radiative symmetry breaking mechanism (RSBM) is investigated. In the context of the simplest model where the implementation of the RSBM is possible, we find that in the majority of the parameter space R-parity is spontaneously broken at the low-scale. These results hint at the possibility that R-parity violating processes will be observed at the Large Hadron Collider, if Supersymmetry is realized in nature.

I. INTRODUCTION

The minimal supersymmetric standard model (MSSM) is considered as one of the most appealing extensions of the standard model of strong and electroweak interactions. This theory has a variety of appealing characteristics including solutions to the hierarchy problem and a dark matter candidate. However, at the renormalizable level, the MSSM Lagrangian contains flagrant baryon and lepton number violating operators, the most infamous of which lead to rapid proton decay (See Ref. [1] for a review on supersymmetry (SUSY) and Ref. [2] for the study of the proton decay issue in SUSY).

The most common approach to this problem is the introduction of a discrete symmetry, $R$-parity, defined as $R = (-1)^{3(B-L)+2S}$, where $B$, $L$ and $S$ are baryon and lepton number, and spin, respectively (See Ref. [3] for a review on $R$-parity violation.). The conservation of $R$-parity has the added bonus of insuring that the lightest SUSY particle (LSP) is stable and therefore a cold dark matter candidate. While $R$-parity is closely linked to $B - L$, they are not synonymous. Specifically, $R$-parity allows for terms that break $B - L$ by an even amount. For general arguments on $R$-parity conservation see Refs. [4] and [5].

In order to understand the conservation or violation of $R$-Parity one has to consider theories where $B - L$ is part of the gauge symmetry. In such cases $R$-parity is an exact symmetry as long as the same is true for $B - L$. Breaking $B - L$ by a field with even charge (the canonical $B - L$ model) guarantees automatic $R$-parity conservation even below the symmetry scale, since only $B - L$ violation by an even amount is allowed. An alternative is $B - L$ breaking through the right-handed sneutrino, a field which must always be included due to anomaly cancellation. Since the right-handed sneutrino has a charge of one, its VEV results in spontaneous $R$-parity violation. Phenomenologically, this is a viable scenario that does not induce tree-level rapid proton decay and dark matter is still possible if the gravitino is the LSP.
Recently, spontaneous \( R \)-parity violation has been studied in the case of minimal \( B - L \) models [6–10]. However, the following question is still relevant: Does the canonical \( B - L \) model favors \( R \)-parity conservation or violation? In this letter we study this question in the simplest local \( U(1)_{B-L} \) extension of the MSSM assuming for simplicity MSUGRA boundary conditions for the soft terms. We investigate the fate of \( R \)-parity using the radiative symmetry breaking mechanism and show that for the majority of the parameter space, \( R \)-parity is broken, namely it is the right-handed sneutrino that acquires a negative mass squared and therefore a vacuum expectation value (VEV). This is a surprising result that at the very least questions the feasibility of conserving \( R \)-parity in such a framework. These results are quite general and apply to any SUSY theory where \( B - L \) is part of the gauge symmetry.

II. THEORETICAL FRAMEWORK

We investigate the possible connection between RSBM and the fate of \( R \)-parity in the simplest \( B - L \) model, based on the gauge group:

\[
SU(3) \otimes SU(2)_L \otimes U(1)_Y \otimes U(1)_{B-L}
\]

with particle content listed in Table I.

| Field \( \hat{Q} = (\hat{u}, \hat{d}) \) | \( SU(2)_L \) | \( U(1)_Y \) | \( U(1)_{B-L} \) |
|---|---|---|---|
| \( \hat{u}^c \) | 1 | -2/3 | -1/3 |
| \( \hat{d}^c \) | 1 | 1/3 | -1/3 |
| \( \hat{L} = (\hat{\nu}, \hat{e}) \) | 2 | -1/2 | -1 |
| \( \hat{e}^c \) | 1 | 1 | 1 |
| \( \hat{\nu}^c \) | 1 | 0 | 1 |
| \( \hat{H}_u = (\hat{H}_u^+, \hat{H}_u^0) \) | 2 | 1/2 | 0 |
| \( \hat{H}_d = (\hat{H}_d^0, \hat{H}_d^-) \) | 2 | -1/2 | 0 |
| \( \hat{X} \) | 1 | 0 | -2 |
| \( \hat{\bar{X}} \) | 1 | 0 | 2 |

TABLE I: \( SU(2)_L \otimes U(1)_Y \otimes U(1)_{B-L} \) charges for the particle content.
The most general superpotential is given by

\[ W = W_{\text{MSSM}} + W_{B-L}, \tag{1} \]

\[ W_{\text{MSSM}} = Y_u \hat{Q} \hat{H}_u \hat{u}^c + Y_d \hat{Q} \hat{H}_d \hat{d}^c + Y_e \hat{L} \hat{H}_d \hat{e}^c + \mu \hat{H}_u \hat{H}_d, \tag{2} \]

\[ W_{B-L} = Y_\nu \hat{L} \hat{H}_u \nu^c + f \nu^c \bar{\nu}^c \bar{X} - \mu_X \bar{X} \hat{X}, \tag{3} \]

and the corresponding soft SUSY breaking Lagrangian is

\[ -\mathcal{L}_{\text{Soft}} \supset \left( a_\nu \bar{L} H_u \nu^c - a_X \nu^c \bar{\nu}^c X - b_X X \bar{X} + \frac{1}{2} M_{BL} \bar{B}' B' + \text{h.c.} \right) + m_X^2 |X|^2 + m_{\bar{\nu}^c}^2 |\bar{\nu}^c|^2, \tag{4} \]

where we have suppressed flavor and group indices and \( \bar{B}' \) is the \( B-L \) gaugino.

Spontaneous \( B-L \) violation requires either the VEV of \( X, \bar{X} \) or \( \nu^c \) to be nonzero, however the fate of \( R \)-parity lies solely in the VEV of \( \nu^c \): \( \langle \nu^c \rangle = 0 \) corresponds to \( R \)-parity conservation while \( \langle \nu^c \rangle \neq 0 \) indicates spontaneous \( R \)-parity violation. Addressing the values of these VEVs requires the minimization conditions which can be derived from the full potential where \( \left( \langle X \rangle, \langle \bar{X} \rangle, \langle \nu^c \rangle \right) = 1/\sqrt{2} (x, \bar{x}, n) \):

\[ \langle V \rangle = \langle V_F \rangle + \langle V_D \rangle + \langle V_{\text{Soft}} \rangle, \tag{5} \]

\[ \langle V_F \rangle = \frac{1}{4} f^2 n^4 + f^2 n^2 x^2 + \frac{1}{2} \mu_X^2 (x^2 + \bar{x}^2) - \frac{1}{\sqrt{2}} f \mu_X n^2 \bar{x}, \tag{6} \]

\[ \langle V_D \rangle = \frac{1}{32} g_{BL}^2 (2 \bar{x}^2 - 2 x^2 + n^2)^2, \tag{7} \]

\[ \langle V_{\text{Soft}} \rangle = -\frac{1}{\sqrt{2}} a_X n^2 x - b_X x \bar{x} + \frac{1}{2} m_X^2 x^2 + \frac{1}{2} m_{\bar{\nu}^c}^2 \bar{x}^2 + \frac{1}{2} m_{\bar{\nu}^c}^2 n^2. \tag{8} \]

Only two cases exist for spontaneous \( B-L \) symmetry breaking: Case i) \( n = 0; x, \bar{x} \neq 0 \) implying \( R \)-parity conservation or Case ii) \( x, \bar{x}, n \neq 0 \) implying spontaneous \( R \)-parity violation. Note that a third case, \( n \neq 0; x, \bar{x} = 0 \) cannot exist due to the linear term for \( x \) in Eq. (8) and for \( \bar{x} \) in Eq. (6), which always induce a VEV for these fields.

- **Case i): R-Parity Conservation**

  This is the traditional case studied in the literature. The minimization conditions for \( x \) and \( \bar{x} \) are very similar in form to those of \( v_u \) and \( v_d \) in the MSSM:

  \[ \frac{1}{2} M_{Z'}^2 = -|\mu_X|^2 + \frac{m_X^2 \tan^2 z - m_{\bar{\nu}^c}^2}{1 - \tan^2 z}, \tag{9} \]

  \footnote{Technically, the left-handed sneutrino has a VEV as well, but in order to generate the correct neutrino masses, this VEV must be quite small compared to the others and so can safely be ignored here.}
where \( \tan z \equiv x/\bar{x} \) and \( M_{Z'}^2 \equiv g_{BL}^2 \left( x^2 + \bar{x}^2 \right) \), which is the mass for the \( Z' \) boson associated with broken \( B - L \).

To attain a better understanding of the situation, let us examine Eq. (9) in the limit \( x \gg \bar{x} \), with \( m_X^2 < 0 \) and \( m_{\bar{X}}^2 > 0 \), so that it reduces to

\[
\frac{1}{2} M_{Z'}^2 = -|\mu_X|^2 - m_X^2. \tag{10}
\]

Since the left-hand side is positive definite, the relationship \( -m_X^2 > |\mu_X|^2 \) must be obeyed for spontaneous \( B - L \) violation: a tachyonic \( m_X^2 \) is not enough. This relationship between \( \mu_X \) and \( m_X \) is similar to the relationship in the MSSM between \( \mu \) and \( m_{H_u} \), a relationship typically referred to as the \( \mu \) problem, i.e. why is \( \mu \) of the order of the SUSY mass scale. Then in case \( i \), in addition to the MSSM \( \mu \) problem, we have introduced a new \( \mu \) problem for \( \mu_X \).

As can be seen from Eq. (10), \( x \) is of order the SUSY mass scale or about a TeV. Replacing \( X \) by its VEV in the term \( f\nu^c\nu^cX \) in the superpotential leads to the heavy Majorana mass term for the right-handed neutrinos and ultimately to the Type I seesaw mechanism \[11\] for neutrino masses:

\[
m_\nu = v_u^2 Y_T \nu^T \left( f x \right)^{-1} Y_\nu. \tag{11}
\]

Since the mass of the right-handed neutrinos are of order TeV, realistic neutrino masses require, \( Y_\nu \sim 10^{-6-7} \). The rest of the spectrum is given in Appendix B.

- **Case ii): R-Parity Violation**

Evaluation of the minimization conditions in this case is illuminating in the limit \( n \gg x, \bar{x}, a_X \) and \( g_{BL}^2 \ll 1 \), which will prove to be the case of interest in the numerical section:

\[
n^2 = \frac{\left( -m_{\tilde{\nu}_e}^2 \right) \Lambda_X^2}{f^2 \left( 2 m_X^2 + \frac{1}{8} g_{BL} \Lambda_X^2 \right)}, \tag{12}
\]

\[
\bar{x} = \frac{\left(-m_{\tilde{\nu}_e}^2\right) f \mu_X}{\sqrt{2} \left( f^2 \left( 2 m_X^2 + \frac{1}{8} g_{BL} \Lambda_X^2 \right) \right)}, \tag{13}
\]

\[
x = \frac{\left( -m_{\tilde{\nu}_e}^2 \right) \left[a_X \Lambda_X^2 + f b_X \mu_X\right]}{(2 f^2 - \frac{1}{4} g_{BL}^2) \Lambda_X^2 + f^2 m_X^2 \Lambda_X^2 + \frac{1}{8} g_{BL}^2 a_X \Lambda_X^2}, \tag{14}
\]

where \( \Lambda_X^2 \equiv \mu_X^2 + m_X^2 \) and \( \Lambda_{\bar{X}}^2 \equiv \mu_{\bar{X}}^2 + m_{\bar{X}}^2 \).

These equations indicate several things: spontaneous \( B - L \) symmetry breaking in the R-parity violating case only requires \( m_{\tilde{\nu}_e}^2 < 0 \) and does not introduce a new \( \mu \) problem so that \( \mu_X \) can be larger than the TeV scale; that \( x \) and \( \bar{x} \) are triggered by linear terms since they go as these linear terms suppressed by the effective mass squared; and all VEVs increase with \( \mu_X \) up to a point after
which \( n \) asymptotes while \( x \) and \( \bar{x} \) decrease as \( 1/\mu_x \). The \( \mu \to \infty \) serves as a decoupling limit since \( x, \bar{x} \to 0 \) and \( n^2 \to -8m_{\tilde{\nu}c}/g_{BL}^2 \) as in the minimal model \([7]\). Neutrino masses in this case will have a more complicated form that will depend both on the type I seesaw contribution and an \( R \)-parity contribution although the bounds on \( Y_\nu \) are similar to Case \( i \). The \( Z' \) mass in this case is

\[
M_{Z'}^2 = \frac{1}{4} \left( n^2 + 4x^2 + 4\bar{x}^2 \right). \tag{15}
\]

and the rest of the spectrum is given in Appendix B.

The important question now becomes: are either of these cases possible from the perspective of RSBM? Specifically, will running from some SUSY breaking boundary conditions drive either \( X \) or \( \tilde{\nu}c \) tachyonic, or neither. To answer this we must turn to a specific SUSY breaking scheme with some predictive power. One of the simplest way to transmit SUSY breaking is through gravity \([12]\) and here we will adopt the MSUGRA Ansatz with the following boundary conditions at the GUT scale:

\[
\begin{align*}
m_X^2 &= m_{\tilde{X}}^2 = m_{\tilde{\nu}c}^2 = ... = m_0^2 \\
A_X &= f A_0; \ A_\nu = Y_\nu A_0; ... \\
M_{BL} &= ... = M_{1/2} 
\end{align*} \tag{16-18}
\]

where ... indicates MSSM parameters.

Finally, we present the renormalization group of equations (RGEs) necessary to evolve the boundary conditions given by MSUGRA down to the SUSY scale, derived using \([13]\). The RGEs will only be functions of the beyond the MSSM couplings since \( Y_\nu \) is small enough to be neglected. We assume that \( g_{BL} \) unifies with the other gauge couplings at the GUT scale of about \( 2 \times 10^{16} \) and for simplicity we use the \( \text{SO}(10) \) GUT renormalization factor, \( \sqrt{3/8} \). In the one family approximation, the RGEs are given by\(^2\)

\[
\begin{align*}
16\pi^2 \frac{dm_{\tilde{\nu}c}^2}{dt} &= \left[ 8f^2 X - 3g_{BL}^2 M_{BL}^2 \right], \tag{19} \\
16\pi^2 \frac{dm_X^2}{dt} &= \left[ 4f^2 X - 12g_{BL}^2 M_{BL}^2 \right], \tag{20} \\
16\pi^2 \frac{dm_{\tilde{X}}^2}{dt} &= -12g_{BL}^2 M_{BL}^2, \tag{21}
\end{align*}
\]

where \( t = ln \mu \), and \( X \equiv m_X^2 + 2m_{\tilde{\nu}c}^2 + 4a_{\tilde{X}}^2 \). See Appendix A for the full set of RGEs including the contributions from three families of right-handed neutrinos.

Radiative symmetry breaking requires one of the soft masses in Eqs. (19-21) to run negative. Experience from radiative electroweak symmetry breaking in the MSSM \([15]\), indicates that Yukawa terms in the

\(^2\) We would like to note that our results are in disagreement with the results in Ref. \([14]\).
beta functions tend to drive the masses squared negative while gaugino terms do the opposite. Due to its smaller $B-L$ charge, $\tilde{\nu}_c$ has the smallest gaugino factor while also having the largest Yukawa factor. Since in MSUGRA, all of these fields have the same mass at the GUT scale, it is clear that $m^2_{\tilde{\nu}_c}$ will evolve to the smallest value in the simple one family approximation. When including all three values families, $m^2_X$ gets an enhancement from trace of $f$, Eq. (A10), which could lead to it being tachyonic and therefore to $R$-parity conservation. The question of whether RSBM is possible as well as the fate of $R$-parity throughout the parameter space will be addressed numerically in the next section.

III. R-PARITY: CONSERVATION OR VIOLATION ?

In addition to addressing the feasibility of RSBM in general and the fate of $R$-parity specifically, it would also be prudent to identify the part of parameter space that leads to a realistic spectrum. One strong experimental constrain is the bound on the $Z'$ mass: $M_{Z'}/gBL > 5$ TeV [16], indicating the need for a large mass scale, independent of the fate of $R$-parity, and translates into a large value for $m_0$ at the GUT scale.

Common lore dictates that a large mass scale at the GUT scale also leads to large fine-tuning in the MSSM Higgs sector. However, large values of $m_0$ (TeV) and small values of $M_{1/2}$ (few hundred GeV) (the so called focus point region of MSUGRA [17]), provides a remarkable opportunity. In this regime, the $H_u$ soft mass runs slowly to small values that do not require a large amount of fine-tuning while the larger symmetry factors for the Yukawa terms in the $m^2_X$ and $m^2_{\tilde{\nu}_c}$ RGEs, Eq. (A10, A11), run these masses tachyonic faster and naturally lead to a slight hierarchy between the electroweak scale and the $B-L$ scale, as suggested by the hierarchy between the $Z$ mass and the bounds on the $Z'$ mass. This is independent of the status of $R$-parity. Aside from the stops, the remaining soft scalar masses do not run much and the approximations made in the previous section for case ii are valid.

The remainder of the parameters will be chosen as follows: $\tan \beta$ and $f$ values will be inputted at the SUSY scale. Using these values, the Yukawa couplings are evolved up to the GUT scale where $g_{BL}$ is assumed to unify with the other gauge couplings. The MSUGRA parameters are chosen in the focus point regime with $A_0 = 0$ (we find that $A_0$ has very little effect on the results). The SUSY breaking parameters are evolved down to the SUSY scale where the EWSB minimization conditions are used to solve for $\mu$ and $B$. It is also assumed that $B_X = B$ at the GUT scale, where $b_X = B_X \mu_X$. Specifying $\mu_X$ then determines the spectrum.

The feasibility of RSBM, as well as the fate of $R$-parity, rely heavily on $f = \text{diag} (f_1, f_2, f_3)$. Calculating the soft masses of $X$ and $\tilde{\nu}_c$ with increasing $f_3$ yields Fig. [1] for $m_0 = 2000$ GeV, $M_{1/2} = 200$ GeV, $A_0 = 0$ and negligible $f_1$ and $f_2$. As expected, in the $f_1, f_2 \ll f_3$ limit, only the $\tilde{\nu}_c$ mass becomes tachy-
onic, so while RSBM can be successful, it leads to spontaneous $R$-parity breaking. Note that $f_3$ exhibits fixed-point like behavior (as discussed in a similar scenario in [18]). This means that its range allowing for RSBM, corresponds to a larger range of values at the GUT scale.

![Figure 1](image1.png)

**FIG. 1:** Soft masses in the form $\text{sign}(m_2^X)|m_\phi|$ for $X$ (blue) and $\bar{\nu}^c$ (red) versus $f_3$, for $m_0 = 2000$ GeV, $M_{1/2} = 200$ GeV, $A_0 = 0$ and negligible $f_1$ and $f_2$. RSBM is possible for $f_3 \gtrsim 0.51$ and spontaneous $R$-parity violation.

In Fig. 2 are the $X$ and $\bar{\nu}^c$ soft masses for different values $f_3$ versus $m_0$ with all other parameters the same as in Fig. 1. It indicates that the $m_0$ parameter also plays an important role determining the overall size of the tachyonic mass, and therefore the $Z'$ mass, and can even derail RSBM for lower values of $f_3$.

![Figure 2](image2.png)

**FIG. 2:** Soft masses in the form $\text{sign}(m_2^X)|m_\phi|$ for $X$ (blue) and $\bar{\nu}^c$ (red) versus $m_0$ for $f_3 = 0.5$ (solid), 0.52 (dashed), 0.54 (dot-dashed), 0.56 (dotted) and all other parameters the same as in Fig. 1.

For $f_1 \sim f_2 \sim f_3$, the Yukawa term in the RGE for $m_2^X$ is effectively enhanced by a factor of three, see Eq. (A10) as compared to Eq. (20), which can lead to an $R$-parity conserving minima since no such factor
appears for $m_{\tilde{g}_e}^2$. We show these effects in Fig. 3 where red dots indicate spontaneous $R$-parity violation and blue dots show the region of $R$-parity conservation in the $f_2$-$f_1$ plane for $f_3 = 0.4$ (a) and $f_3 = 0.55$ (b) and $m_0 = 2000$ GeV, $M_{1/2} = 200$ GeV and $A_0 = 0$. In Fig. 3(a) $f_1$ or $f_2 \sim 0.52$ is needed for RSBM while only $f_1 \sim f_2 \gtrsim 0.4$ allows for $R$-parity conservation (there is about a 50-50 split between $R$-parity conservation and violation in this graph). If $f_1$ or $f_2 > 0.52$, these couplings are no longer perturbative at the GUT scale. As one increases the value of $f_3$, the $R$-parity conserving points disappear as reflected in Fig. 3(b), which does not allow for $R$-parity conservation. In this case, $f_1$ or $f_2 \gtrsim 0.4$ leads to non-perturbative values at the GUT scale due to the larger value of $f_3$.

FIG. 3: The state of the $B - L$ breaking vacuum in the $f_2$-$f_1$ plane with $m_0 = 2000$ GeV, $M_{1/2} = 200$ GeV and $A_0 = 0$ for $f_3 = 0.4$ (a) and $f_3 = 0.55$ (b). Blue dots indicate $R$-parity conservation while red dots $R$-parity violation. In (a), the empty space below the curve indicates no RSBM, while in both graphs, in the space above the curves, the $f$’s are no longer perturbative at the GUT scale. In (a), there is about an even number of $R$-parity conserving and violating vacua but increasing $f_3$ tips the favor towards $R$-parity violation and eventually only allows for $R$-parity violation as in (b).

The graphs in Fig. 3 are a bit misleading since they are just slices of the three dimensional space $f_1 - f_2 - f_3$, which is displayed in Figs. 4 and 5 with the same legend as the former figure. While these latter figures are perhaps harder to read, one can see that the majority of the parameter space which allows for RSBM is dominated by $R$-parity violation (five times more prevalent) while only $f_1 \sim f_2 \sim f_3$ allows for $R$-parity conservation. Both of these regions sit on a thin shell where $f_1$ or $f_2$ or $f_3 \sim 0.5$. Below this shell, RSBM is not realized. This last figures summarize the findings of this letter quite well: when RSBM is realized the $R$-parity breaking vacuum is more probable than the $R$-parity conserving one, especially when a hierarchy exists within the $f$ matrix. Only when this matrix is fairly degenerate (degenerate right-handed neutrinos) does the running allow for $R$-parity conservation.
FIG. 4: The state of the $B - L$ breaking vacuum in the $f_1 - f_2 - f_3$ space with $m_0 = 2000$ GeV, $M_{1/2} = 200$ GeV and $A_0 = 0$. Blue dots indicate $R$-parity conservation while red dots $R$-parity violation, the latter appears five times more often. The key point is that only fairly degenerate values of $f$ (and therefore the right-handed neutrinos) allow for $R$-parity conservation. We have checked that all physical masses are positive in these cases.

FIG. 5: The state of the $B - L$ breaking vacuum in the $f_1 - f_2 - f_3$ space with $m_0 = 5000$ GeV, $M_{1/2} = 500$ GeV and $A_0 = 0$. Blue dots indicate $R$-parity conservation while red dots $R$-parity violation, the latter appears five times more often. The key point is that only fairly degenerate values of $f$ (and therefore the right-handed neutrinos) allow for $R$-parity conservation. We have checked that all physical masses are positive in these cases.
IV. SUMMARY

The possible origin of the $R$-parity violating interactions in the minimal extension of the standard model and its connection to the radiative symmetry breaking mechanism has been investigated in the simplest possible model. We have found that in the majority of the parameter space $R$-parity is spontaneously broken at the low-scale and the soft SUSY mass scale defines the $B - L$ and $R$-parity breaking scales. These results can be achieved in any extension of the MSSM where $B - L$ is part of the gauge symmetry. The main result of this letter hints at the possibility that $R$-parity violating processes will be observed at the Large Hadron Collider, if Supersymmetry is discovered.

Appendix A: Renormalization Group Equations

We present first the gamma functions, which are useful for deriving the RGEs. Here \( i = 1, 2, 3 \):

\[
\gamma_X = \frac{1}{16\pi^2} \left( 2 \text{Tr} f^2 - 3 g_{BL}^2 \right), \tag{A1}
\]

\[
\gamma_{\bar{X}} = \frac{1}{16\pi^2} \left( -3 g_{BL}^2 \right), \tag{A2}
\]

\[
\gamma_{\nu^c_i} = \frac{1}{16\pi^2} \left( 4 f_i^2 - \frac{3}{4} g_{BL}^2 \right), \tag{A3}
\]

where repeated indices are not summed and \( f = \text{diag} (f_1, f_2, f_3) \), since \( f \) can always be diagonalized by rotating the right-handed neutrino fields. The same holds true here for \( a_X \) due to the MSUGRA Ansatz.

The RGEs are given by

\[
16\pi^2 \frac{dg_{BL}}{dt} = 9 g_{BL}^3, \tag{A4}
\]

\[
16\pi^2 \frac{df_i}{dt} = f_3 \left( 8 f_i^2 + 2 \text{Tr} f^2 - \frac{9}{2} g_{BL}^2 \right), \tag{A5}
\]

\[
16\pi^2 \frac{dM_{BL}}{dt} = 18 g_{BL}^2 M_{BL}, \tag{A6}
\]

\[
16\pi^2 \frac{da_X}{dt} = f_X \left( 16 f_i a_{X_i} + 4 \text{Tr} (f a_X) - 9 g_{BL}^2 M_{BL} \right) \tag{A7}
\]

\[
+ a_{X_i} \left( 8 f_i^2 + 2 \text{Tr} f^2 - \frac{9}{2} g_{BL}^2 \right), \tag{A8}
\]

\[
16\pi^2 \frac{dm_{X_i}}{dt} = -12 g_{BL}^2 M_{BL}^2, \tag{A9}
\]

\[
16\pi^2 \frac{dm_{\bar{X}}}{dt} = \left[ 4 \text{Tr} f^2 m_X^2 + 8 \text{Tr} (f^2 m_{\nu^c}^2) + 4 \text{Tr} a_X^2 - 12 g_{BL}^2 M_{BL}^2 \right], \tag{A10}
\]

\[
16\pi^2 \frac{dm_{\nu^c_i}}{dt} = \left[ 8 f_i^2 \left( m_X^2 + 2 m_{\nu^c}^2 \right) + 8 a_{X_i}^2 - 3 g_{BL}^2 M_{BL}^2 \right]. \tag{A11}
\]

Appendix B: Spectrum

In calculating the following spectrum we assume \( \langle \nu^c_3, X, \bar{X} \rangle = \frac{1}{\sqrt{2}} (n, x, \bar{x}) \) and all others zero.

Pseudoscalar mass matrix in the basis \( \text{Im} (\nu^c_3, X, \bar{X}) \):

\[
\mathcal{M}_P = \begin{pmatrix}
2 \sqrt{2} (a_X x + f_3 \mu_X \bar{x}) & \sqrt{2} a_X n & -\sqrt{2} f_3 \mu_X n \\
\sqrt{2} a_X n & a_X n^2 + \sqrt{2} b_X \bar{x} & b_X \\
-\sqrt{2} f_3 n \mu_X & b_X & f_3 \mu_X n^2 + \sqrt{2} b_X \bar{x}
\end{pmatrix}. \tag{B1}
\]
Scalar mass matrix in the basis $\text{Re} \left( \tilde{\nu}^c_3, X, \bar{X} \right)$:

$$
\mathcal{M}_S = \begin{pmatrix}
(2 f_3^2 + \frac{1}{4} g_{BL}^2) n^2 & (4 f_3^2 - \frac{1}{2} g_{BL}^2) n x - \sqrt{2} a_X n & -\sqrt{2} f_3 \mu_x n + \frac{1}{2} g_{BL}^2 n \bar{x} \\
(4 f_3^2 - \frac{1}{2} g_{BL}^2) n x - \sqrt{2} a_X n & a_n x^2 + \frac{\sqrt{2} b x}{\sqrt{2} x} + g_{BL}^2 x^2 & -b_x - g_{BL}^2 x \bar{x} \\
-\sqrt{2} f_3 \mu_x n + \frac{1}{2} g_{BL}^2 n \bar{x} & -b_x - g_{BL}^2 x \bar{x} & f_{1, \mu X} x^2 + \frac{\sqrt{2} b x}{\sqrt{2} x} + g_{BL}^2 \bar{x}^2
\end{pmatrix}.
$$

Neutralino mass matrix in the basis $\left( B', \nu^c, \bar{X}, \tilde{X} \right)$:

$$
\mathcal{M}_{\chi^0} = \begin{pmatrix}
M_{BL} & \frac{1}{2} g_{BL} n & -g_{BL} x & g_{BL} \bar{x} \\
\frac{1}{2} g_{BL} n & \sqrt{2} f_3 n & \sqrt{2} f_3 n & 0 \\
-g_{BL} x & \sqrt{2} f_3 n & 0 & -\mu_X \\
g_{BL} \bar{x} & 0 & -\mu_X & 0
\end{pmatrix}.
$$

The sfermion mass, with matrices in the basis $\left( \tilde{f}_L, \tilde{f}_R \right)$

$$
\mathcal{M}^2_u = \begin{pmatrix}
m_{Q}^2 + m_u^2 - \frac{1}{8} \left( g_2^2 - \frac{1}{4} g_1^2 \right) (v^2_u - v^2_d) + \frac{1}{3} D_{BL} & \frac{1}{\sqrt{2}} (a_u v_u - Y_u \mu v_d) \\
\frac{1}{\sqrt{2}} (a_u v_u - Y_u \mu v_d) & m_{\tilde{c}}^2 + m_u^2 - \frac{1}{8} g_1^2 (v^2_u - v^2_d) - \frac{1}{3} D_{BL}
\end{pmatrix},
$$

$$
\mathcal{M}^2_d = \begin{pmatrix}
m_{Q}^2 + m_d^2 + \frac{1}{8} \left( g_2^2 + \frac{1}{4} g_1^2 \right) (v^2_u - v^2_d) + \frac{1}{3} D_{BL} & \frac{1}{\sqrt{2}} (Y_d \mu v_u - a_d v_d) \\
\frac{1}{\sqrt{2}} (Y_d \mu v_u - a_d v_d) & m_{\tilde{e}}^2 + m_d^2 + \frac{1}{12} g_1^2 (v^2_u - v^2_d) - \frac{1}{3} D_{BL}
\end{pmatrix},
$$

$$
\mathcal{M}^2_e = \begin{pmatrix}
m_{Q}^2 + m_e^2 + \frac{1}{8} \left( g_2^2 - g_1^2 \right) (v^2_u - v^2_d) - D_{BL} & \frac{1}{\sqrt{2}} (Y_e \mu v_u - a_e v_d) \\
\frac{1}{\sqrt{2}} (Y_e \mu v_u - a_e v_d) & m_{\tilde{e}}^2 + m_e^2 + \frac{1}{2} g_1^2 (v^2_u - v^2_d) + D_{BL}
\end{pmatrix},
$$

$$
m_{\tilde{\nu}_{L}}^2 = m_{\tilde{\nu}_{L}}^2 - \frac{1}{8} \left( g_2^2 + g_1^2 \right) (v^2_u - v^2_d) - D_{BL},
$$

$$
m_{\tilde{N}_{Li}}^2 = m_{\tilde{\nu}_{i}}^2 + 2 f_i^2 x^2 - f_i f_3 n^2 + \sqrt{2} a_{X_i} x + \sqrt{2} f_i \mu X \bar{x} + D_{BL},
$$

$$
m_{\tilde{N}_{Ri}}^2 = m_{\tilde{\nu}_{i}}^2 + 2 f_i^2 x^2 + f_i f_3 n^2 - \sqrt{2} a_{X_i} x - \sqrt{2} f_i \mu X \bar{x} + D_{BL}.
$$

where $D_{BL} \equiv \frac{1}{8} g_{BL}^2 \left( 2 x^2 - 2 x^2 + n^2 \right)$, and $m_u$, $m_d$ and $m_e$ are the respective fermion masses and $a_u$, $a_d$ and $a_e$ are the trilinear $a$-terms corresponding to the Yukawa couplings $Y_u$, $Y_d$ and $Y_e$. The right-handed sneutrino eigenstates are the scalars $\tilde{N}_{Ri}$ and pseudoscalars $\tilde{N}_{Li}$, where $i$ runs only over the first two generations and repeated indices are not summed. The third generation mixes with the Higgses, Eqs. (B1-B2). The above masses are for $R$-parity violation, case $ii$ from the text. For the $R$-parity conserving case,
case $i$, take the limit $n \to 0$ and the $B - L$ Higgs masses are given by the lower two-by-two block matrices of Eqs. (B1, B2) and $i$ in Eqs. (B8, B9) runs over all three generations.
