EQUIVARIANT BATALIN-VILKOVISKY FORMALISM

F. BONECHI, A. S. CATTANEO, J. QIU, AND M. ZABZINE

Abstract. We study an equivariant extension of the Batalin-Vilkovisky formalism for quantizing gauge theories. Namely, we introduce a general framework to encompass failures of the quantum master equation, and we apply it to the natural equivariant extension of AKSZ solutions of the classical master equation (CME). As examples of the construction, we recover the equivariant extension of supersymmetric Yang-Mills in 2d and of Donaldson-Witten theory.

1. Introduction

One cannot overlook the role played by equivariant methods in quantum field theory in the last thirty years. The different versions of equivariant localization played central role in obtaining the exact results for supersymmetric field theories. One prominent example is the construction of \( N = 2 \) 4d supersymmetric theory in \( \Omega \)-background \cite{11} (the equivariant version of the Donaldson-Witten theory). Later these ideas were implemented and generalized to other field theoretical examples, mainly within supersymmetric field theory context. Here we would like to address the equivariance from more gauge theoretical point of view, namely within the the Batalin-Vilkovisky formalism.

Many of the above examples of gauge theories whose equivariant extension proved to be so fruitful have a very simple description in terms of the Batalin-Vilkovisky (BV) formalism and in particular can be formulated as AKSZ actions \cite{1} (also see \cite{16} for an introduction). Namely, in order to construct the BV extension of a given action one has to double the fields and the ghosts by adding the antifields; in this way one gets an odd symplectic manifold and the BV action is a degree zero solution of the classical master equation \cite{2, 3, 4}

\[
\{S, S\} = 0,
\]

such that the original gauge invariant action is recovered from \( S \) by putting the antifields to zero. Provided \( S \) is extended to solve the
quantum master equation (2), the path integral of the gauge fixed theory is then recovered by integrating \( \exp(iS/\hbar) \) over a Lagrangian submanifold obtained by fixing the antifields in a way that the action is now nondegenerate; invariance under the change of gauge fixing is interpreted as invariance of the BV integration under the deformation of the Lagrangian submanifold.

The AKSZ construction provides a solution \( S \) of the CME (1) in terms of a very transparent geometrical procedure. Indeed, it is very easy extend the AKSZ solution to an action satisfying the equivariant version (10) of (1). On the other hand, since the CME is not anymore satisfied, the BV formalism must be modified, in particular one has to understand how to guarantee the invariance of the path integral under the change of Lagrangian submanifold. This paper is devoted to developing the proper setting to deal with equivariance in the framework of the Batalin-Vilkovisky method.

In Section 2 we discuss how we can encompass actions that fail to solve the quantum master equations still keeping the spirit of the BV formalism, i.e. invariance of the integral under deformations of the Lagrangian submanifold. This is in principle possible provided we accordingly restrict the class of observables and of Lagrangian submanifolds in a way that is compatible with the failure \( T \) of the QME. Apart from some additional conditions, this setting is equivalent to working in the symplectic reduction defined by the zero locus \( C_T \) of \( T \) (see Remark 2.1). In Section 3 we apply this formalism to the equivariantly extended AKSZ solution. The formalism leads us to consider a complex that is a quantum version of the Cartan model for the equivariant cohomology of the \( g \)-differential algebra defined on the space of AKSZ fields. In Section 4 we consider as an example SUSY Yang-Mills in two dimensions. The equivariant extension was considered in [13]. Here we prove that BV complex of fields contains the supersymmetric multiplet in the \( \Omega \)-background considered in [13]. Moreover, we study the equivariant observables by using a method that was introduced in [5]. In Section 5 we study the AKSZ version of the topological twist of \( N = 2 \) supersymmetric 4d Yang-Mills theory considered in [17] and its equivariant extension [11] [12].

2. RELAXING THE QUANTUM MASTER EQUATION

The fundamental fact of the BV formalism is that, given a family $L_t$ of Lagrangian submanifolds of the BV space and a half density $\rho$, one has

$$\frac{d}{dt} \int_{L_t} \rho = 0,$$

if $\Delta \rho = 0$ with $\Delta$ being the canonical BV Laplacian on half densities.

Typically we fix a reference $\Delta$-closed half density $\rho$ and on the algebra $\mathcal{A}$ of functions we define $\Delta f := (\Delta(\rho f))/\rho$, for any $f \in \mathcal{A}$, where in the r.h.s. we use the canonical BV Laplacian on half densities. By $\int_{\mathcal{L}} f$ from now on we mean $\int_{\mathcal{L}} f \rho$. The above statement now becomes

$$\frac{d}{dt} \int_{L_t} f = 0,$$

if $\Delta f = 0$.

The main application of this is that the integral of a $\Delta$-closed function is invariant under deformations of the Lagrangian submanifold on which we integrate. More generally, the integral of $f$ is invariant under deformations if we restrict ourselves to the class of Lagrangian submanifolds on which $\Delta f$ vanishes. We will pursue this idea here.

In quantum field theory, one usually considers functions of the form $e^{\frac{i}{\hbar}S}$, where $S$ is a function of even degree. From the properties of the BV Laplacian on functions, it follows that $\Delta e^{\frac{i}{\hbar}S} = 0$ if and only if $S$ satisfies the quantum master equation

$$(2) \quad \frac{1}{2} \{S, S\} - i\hbar \Delta S = 0.$$

In this case, the “gauge fixed partition function” $\int_{\mathcal{L}} e^{\frac{i}{\hbar}S}$ is invariant under deformations of $\mathcal{L}$. One is also interested in inserting a second function $\mathcal{O}$, called a preobservable, in the integral. One then has that also $\int_{\mathcal{L}} e^{\frac{i}{\hbar}S} \mathcal{O}$ is invariant under deformations of $\mathcal{L}$ if, in addition, $\Delta_S \mathcal{O} = 0$, where $\Delta_S$ is the $e^{\frac{i}{\hbar}S}$ twisted coboundary operator defined as

$$\Delta_S \mathcal{O} := e^{-\frac{i}{\hbar}S} \Delta (e^{\frac{i}{\hbar}S} \mathcal{O}) = \Delta \mathcal{O} + \frac{i}{\hbar} Q \mathcal{O}$$

with $Q := \{S, \}$. One calls a $\Delta_S$-closed preobservable an observable.

More generally, without assuming the quantum master equation, we define

$$(3) \quad T := \left( \frac{\hbar}{\imath} \right)^2 e^{-\frac{i}{\hbar}S} \Delta e^{\frac{i}{\hbar}S} = \frac{1}{2} \{S, S\} - i\hbar \Delta S$$
and note that now

\begin{equation}
\Delta_{S,T} \mathcal{O} := e^{-\frac{i}{\hbar} S} \Delta(e^{\frac{i}{\hbar} S} \mathcal{O}) = \Delta \mathcal{O} + \frac{i}{\hbar} Q \mathcal{O} + \left(\frac{1}{\hbar}\right)^2 T \mathcal{O}.
\end{equation}

In particular, since \( T \) is proportional to \( \Delta_{S,T} 1 \) we get \( \Delta_{S,T} T = 0 \), which, using the fact that \( T \) is odd and hence satisfies \( T^2 = 0 \), gives

\begin{equation}
\Delta T + \frac{i}{\hbar} QT = 0.
\end{equation}

As remarked above, \( \int_L e^{\frac{i}{\hbar} S} \) is invariant under deformations of \( L \) if we restrict ourselves to the class of Lagrangian submanifolds on which \( T \) vanishes, we will call them \( T \)-Lagrangian submanifolds and from now on we restrict our attention to this class of Lagrangian submanifolds. We then observe the following:

(1) \( \int_L e^{\frac{i}{\hbar} S} \mathcal{O} = 0 \) if \( \mathcal{O} \) is proportional to \( T \), and

(2) \( \int_L e^{\frac{i}{\hbar} S} \mathcal{O} \) is invariant under deformations of \( L \) if \( \Delta_{S,T} \mathcal{O} \) is proportional to \( T \).

This suggests working modulo the ideal \( \mathcal{I}_T \) generated by \( T \). Note however that

\begin{equation}
\Delta_{S,T}(T \mathcal{O}) = -T \Delta_{S,T} \mathcal{O} - \{T, \mathcal{O}\}.
\end{equation}

This means that \( \mathcal{I}_T \) becomes a \( \Delta_{S,T} \)-differential ideal only after restricting to the subalgebra \( \mathcal{N}_T \) of functions that Poisson commute with \( T \), possibly up to a term proportional to \( T \):

\begin{equation}
\mathcal{N}_T = \{ \mathcal{O} \in \mathcal{A} \mid \{T, \mathcal{O}\} \in \mathcal{I}_T \}.
\end{equation}

Note that \( T \) is contained in \( \mathcal{N}_T \), since by degree reasons \( \{T, T\} = 0 \). Actually, \( \mathcal{N}_T \) is the Lie normalizer of \( \mathcal{I}_T \) (i.e., the largest Lie subalgebra of \( (\mathcal{A}, \{\ , \}) \) that contains \( \mathcal{I}_T \) as a Lie ideal). As a consequence, \( \mathcal{A}_T := \mathcal{N}_T/\mathcal{I}_T \) inherits the structure of a Poisson algebra, whose elements we call the quantum preobservables. Moreover, \( \Delta_{S,T} \) descends to a coboundary operator on \( \mathcal{A}_T \) by

\[
\Delta_{S,T}[\mathcal{O}] := [\Delta_{S,T} \mathcal{O}] = \left[ \Delta \mathcal{O} + \frac{i}{\hbar} Q \mathcal{O} \right].
\]

We call a \( \Delta_{S,T} \)-closed quantum preobservable a quantum observable. Note in particular that the unit 1 belongs to \( \mathcal{N}_T \) and that its equivalence class \([1]\) is a unit in \( \mathcal{A}_T \) and an observable.

We may finally summarize the above discussion by observing that

(1) for every observable \([\mathcal{O}]\) we may define \( \int_L e^{\frac{i}{\hbar} S}[\mathcal{O}] \) as \( \int_L e^{\frac{i}{\hbar} S} \mathcal{O} \) where \( \mathcal{O} \) is any representative in \([\mathcal{O}]\), and
(2) $\int_{\mathcal{L}} e^{\frac{i}{\hbar} S}\mathcal{O}$ is invariant under deformations of $T$-Lagrangian $\mathcal{L}$ if $\mathcal{O}$ is a quantum observable.

**Remark 2.1.** The Poisson algebra $\mathcal{A}_T$ may also be interpreted as the algebra of $\{T,\cdot\}$-invariant elements in $\mathcal{A}/\mathcal{I}_T$, which in turn may be interpreted as the algebra of functions on the zero locus $\mathcal{C}_T$ of $T$. Thus, we may interpret $\mathcal{A}_T$ as the algebra of functions on the symplectic reduction $\mathcal{C}_T$ of $\mathcal{C}_T$. Moreover, the condition that $T$ vanishes on a Lagrangian submanifold $\mathcal{L}$ geometrically means that $\mathcal{L}$ is contained in $\mathcal{C}_T$. We may then be tempted to interpret the whole theory as the usual BV formalism but on $\mathcal{C}_T$. This is correct if $e^{i\hbar S}$ is in $\mathcal{N}_T$. Notice however that a gauge fixing Lagrangian submanifold contained in $\mathcal{C}_T$ necessarily contains the characteristic foliation generated by $\{T,-\}$ so that this cannot be a full gauge fixing. For this reason we have to assume that the leaves are compact. $\square$

**Remark 2.2.** By (5) the condition that $e^{i\hbar S}$ is in $\mathcal{N}_T$ occurs if and only if $\Delta T$ is proportional to $T$. One simple, but rather common, case when this happens is when $S$ is a solution of the classical master equation $\{S,S\} = 0$, which implies $T = -i\hbar \Delta S$ and hence $\Delta T = 0$. This may give the impression that we have an amenable way of treating anomalous theories, i.e., theories in which the action $S$ is a solution to the classical master equation that cannot be deformed to a solution of the quantum one. The problem, apart from having to consider an algebra of preobservables different from $\mathcal{A}$, is that it might be difficult to find a natural gauge fixing Lagrangian $\mathcal{L}$ in $\mathcal{C}_T$.

In the rest of the paper we will specialize to the case of an AKSZ theory where we deform the de Rham differential in the source manifold to the equivariant differential w.r.t. the infinitesimal action of some Lie algebra. In this case, several pleasant facts occur. First, $\Delta T = 0$. Second, there are natural choices of $\mathcal{L}$ in $\mathcal{C}_T$. Finally, we will see that $\mathcal{A}_T$ contains an interesting subalgebra, related to the Cartan model, in which $T$ generates again a Lie differential ideal.

### 3. Equivariant AKSZ

We now discuss the equivariant extension of the AKSZ construction. Let $\Sigma$ be a $d$-dimensional manifold with a Lie algebra $\mathfrak{g}$ acting on it via the vector fields $v_X$ for any $X \in \mathfrak{g}$. Let $\mathcal{M}$ be a graded manifold with a symplectic form of degree $d-1$ and a homological Hamiltonian $\Theta \in C^d(\mathcal{M})$; we denote with $D_\Theta$ its Hamiltonian vector field. Let $\mathcal{F}_\Sigma = \text{Map}(T[1]\Sigma, \mathcal{M})$ be the AKSZ space of fields. The BV vector
field is given by

\[ Q_{BV} = \hat{d}_\Sigma + \hat{D}_\Theta = \{S_{BV}, -\}, \]

where \( S_{BV} = S_0 + S_\Theta \) and \( S_0 \) and \( S_\Theta \) are the Hamiltonians of \( \hat{d}_\Sigma \) and \( \hat{D}_\Theta \), respectively. Here we denote with \( \hat{v} \) the vector field of \( \mathcal{F}_\Sigma \) obtained from a vector field \( v \) either of the source \( \Sigma \) or of the target \( \mathcal{M} \) by composing it with maps. Since \( D^2_\Theta = 0 \), \( Q^2_{BV} = 0 \) and \( S_{BV} \) solves the classical master equation \( \{S_{BV}, S_{BV}\} = 0 \).

The space of functionals \( \mathcal{A} = C(\mathcal{F}_\Sigma) \) is a \( \mathfrak{g} \)-dg algebra with differential \( Q_{BV} = \hat{d}_\Sigma + \hat{Q} \), contraction \( \hat{i}_vX \) and Lie derivative \( \hat{L}_vX \) for any \( X \in \mathfrak{g} \). They are all Hamiltonian vector fields with Hamiltonians \( S_{BV}, \hat{i}_vX \) and \( \hat{L}_vX \) respectively (see Appendix A for notations). We recall that \( \mathcal{A}[u] = C(\mathcal{F}_\Sigma) \otimes S\mathfrak{g}^* \). We denote with \( \langle c_a \rangle \) a basis of \( \mathfrak{g} \).

Let us define the equivariant extension of the BV action in the Cartan model as

\[ S^c_{BV} = S_{BV} - u^a S_{i_va}, \]

so that

\[ Q^c_{BV} = \{S^c_{BV}, -\} = \hat{d}_\Sigma + \hat{D}_\Theta - u^a \hat{i}_v a \]

is the differential of the Cartan model of equivariant cohomology. If for \( X \in \mathfrak{g} \) we denote \( L_X = -X^a f^c_{ab} \frac{\partial}{\partial u^b} \frac{\partial}{\partial v^c} \) and \( \mathcal{L}_X = L_X + \hat{L}_vX \), then we have that

\[ \mathcal{L}_X S^c_{BV} = 0, \]

i.e. \( S^c_{BV} \in \mathcal{A}[u]\mathfrak{g} \); moreover \( S^c_{BV} \) satisfies the modified Classical Master Equation

\[ \frac{1}{2}\{S^c_{BV}, S^c_{BV}\} + u^a \hat{L}_{i_v a} = 0. \]

As in (3), we define

\[ T := \frac{1}{2}\{S^c_{BV}, S^c_{BV}\} - i\hbar \Delta S^c_{BV} = -u^a S_{L_v a} - i\hbar \Delta S^c_{BV}, \]

so that

\[ T = -u^a (S_{L_v a} + i\hbar S_{i_v a}) - i\hbar S_{BV}. \]

Since \( S_0 \) and \( S_{i_v a} \) are quadratic in the fields, then \( \Delta \) applied to them will produce constant functionals so that

\[ \{\Delta S_0, -\} = \{\Delta S_{i_v a}, -\} = 0, \quad X \in \mathfrak{g}. \]

These functionals should be thought of as regularized traces of the corresponding operators \( \hat{d}_\Sigma \) and \( \hat{i}_{vX} \); since these operators are odd a
reasonable definition of the trace should be 0, but it is enough to assume from now on that our regularization of $\Delta$ satisfies (13).

Equations (13) have the following interesting consequences. The first one is that, consistent with the rules of the BV algebra, $\Delta S_{L^X} = 0$ for all $X \in g$; in fact

$$\Delta S_{L^X} = \Delta \{ S_0, S_{i^X} \} = \{ \Delta S_0, S_{i^X} \} \pm \{ S_0, \Delta S_{i^X} \} = 0.$$ 

This in particular implies that $\Delta T = 0$,

\begin{align*}
[\Delta, \hat{L}_X] &= 0 \\
Q_{c}^{e}BV T &= 0,
\end{align*}

so that $S_{c BV} \in \mathcal{N}_T$. We are then in the situation discussed at the end of Remark 2.1. Applying $\Delta$ to $\{ S_{L^a}, S_{i^b} \}$ we get the relations

\begin{align*}
f_{c}^{ab} \Delta S_{i^c} &= 0 .
\end{align*}

The last consequence of (13) is that

$$\{ T, \mathcal{O} \} = \{ T', \mathcal{O} \} ,$$

where

$$T' = -u^a S_{L^a} - i\hbar \Delta S_{\Theta} .$$

Following the general discussion of the previous section, we can now write

$$\mathcal{N}_T = \{ \mathcal{O} \in \mathcal{A}[u], \{ T', \mathcal{O} \} \in \mathcal{I}_T \}$$

where $\mathcal{I}_T$ is the ideal generated by $T$ in $\mathcal{A}[u]$.

We can now define an interesting subalgebra of $\mathcal{N}_T$. A stronger condition than $\{ T', \mathcal{O} \} \in \mathcal{I}_T$ is given by the conditions

\begin{align*}
L_a \mathcal{O} &= 0 = \{ \Delta S_{\Theta}, \mathcal{O} \} \quad \forall a .
\end{align*}

In fact the conditions $L_a \mathcal{O} = 0$ for all $a$ imply $u^a \{ S_{L^a}, \mathcal{O} \} = u^a \hat{L}_a \mathcal{O} = 0$ (note that $u^a L_a = 0$). We then define

\begin{align*}
\mathcal{N}_T' = \{ \mathcal{O} \in \mathcal{A}[u], L_X \mathcal{O} = 0 = \{ \Delta S_{\Theta}, \mathcal{O} \} \forall X \in g \} \subset \mathcal{N}_T .
\end{align*}

Recall that $\Delta_{S,T}$ is the twisted BV laplacian defined in (4).

**Proposition 3.1.** Under the hypothesis (13), $\mathcal{N}_T'$ is a Poisson subalgebra that is invariant under both $Q_{c}^{e}BV$ and $\Delta_{S,T}$. Moreover, $T \in \mathcal{N}_T'$.

**Proof.** A direct computation shows that $[L_X, Q_{c}^{e}BV] = 0$, for all $X \in g$. Moreover, we have that

$$\{ \Delta S_{\Theta}, S_{c BV}^{e} \} = \{ \Delta S_{c BV}^{e}, S_{c BV}^{e} \} = \frac{i}{\hbar} \{ (T + u^a S_{L^a}), S_{c BV}^{e} \}$$
\[
\frac{i}{\hbar}(Q_{BV}^c(T) + u^a L_a S_{BV}^c) = \frac{i}{\hbar} Q_{BV}^c(T) = 0 ,
\]
where we used (13) in the first equality, (11) in the second one and (15) in the last one. We then proved invariance under \( Q_{BV}^c \).

Invariance under \( \Delta_{S,T} \) follows from iv) of the two following Lemmas; the last statement follows from iii) of those Lemmas. \( \square \)

**Lemma 3.2.** The following relations are valid for all \( X \in g \):

i) \( [L_X, \Delta] = 0 \);

ii) \( [L_X, Q_{BV}^c] = 0 \);

iii) \( L_X(T) = 0 \);

iv) \( [L_X, \Delta_{S,T}] = 0 \).

**Proof.** Property i) follows from (14) and the fact that \( \Delta \) clearly commutes with \( L_a \). To prove property ii), we first observe that \( L_a \) clearly commutes with \( \hat{Q} \) and \( \hat{d}_\Sigma \); moreover

\[
[L_a, u^b \hat{i}_{vb}] = [\hat{L}_{va}, u^b \hat{i}_{vb}] + [L_a, u^b \hat{i}_{vb}] = u^b [\hat{L}_{va}, \hat{i}_{vb}] + [L_a, u^b \hat{i}_{vb}] = 0 .
\]

To prove property iii), we write \( T = T_0 + C - i\hbar \Delta S_{BV} \), where

\[
T_0 = -u^a S_{L_{va}}
\]

and \( C \) is the constant functional \( +iuh \Delta S_{L_{va}} \). We prove first that \( L_a(T_0) = 0 \). Indeed,

\[
\hat{L}_{va}(T_0) = -u^b \hat{L}_{va}(S_{L_{vb}}) = -u^b f_{ab} c S_{L_{vc}} = -L_a(T_0)
\]

so that \( L_a(T_0) = 0 \). Moreover, \( \hat{L}_{va}(C) = 0 \) since \( C \) is constant and equation (16) implies \( L_a C = 0 \). Finally \( \hat{L}_{va} \Delta S_{BV} = \Delta \hat{L}_{va} S_{BV} = 0 \) from (14) and obviously \( L_a \Delta S_{BV} = 0 \).

Property iv) is an immediate consequence of the previous ones. \( \square \)

**Lemma 3.3.** Let \( V_{\Delta S_\Theta} \) be the Hamiltonian vector field of \( \Delta S_\Theta \). We have that

i) \( [V_{\Delta S_\Theta}, \Delta] = 0 \);

ii) \( [V_{\Delta S_\Theta}, Q_{BV}^c] = 0 \);

iii) \( V_{\Delta S_\Theta}(T) = 0 \);

iv) \( [V_{\Delta S_\Theta}, \Delta_{S,T}] = 0 \).

**Proof.** Property i) follows since, being \( \Delta \) a derivation of the odd bracket, \( [\Delta, V_{\Delta S_\Theta}] = V_{\Delta^2 S_\Theta} = 0 \). In order to prove ii), let us write

\[
\{\Delta S_\Theta, S_{BV}^c\} = \{\Delta S_{BV}^c, S_{BV}^c\} = \frac{1}{2} \Delta \{S_{BV}^c, S_{BV}^c\} = -u^a \Delta S_{L_{va}} = 0 ,
\]

where we used (13) in the first equality, (11) in the second one and (15) in the last one. We then proved invariance under \( Q_{BV}^c \).
where the second equality holds because $\Delta$ is a derivation of the odd bracket, the third follows from the modified classical master equation (10) and the fourth one from (14).

Let us prove $iii)$. From the obvious equation $\{T, T\} = 0$ we finally get

$$0 = \{u^a S_{\hat{L}} + i\hbar \Delta S_\Theta, T\} = u^a L_a(T) + i\hbar \{\Delta S_\Theta, T\} = i\hbar \{\Delta S_\Theta, T\},$$

where we used $iii)$ of Lemma 3.2 Property $iv)$ is a consequence of $i - iii)$. □

Remark that $Q_{\text{cBV}}$ squares to zero when restricted to $\mathcal{N}_T'$; we call $(\mathcal{N}_T', Q_{\text{cBV}})$ the algebra of classical equivariant BV preobservables. A classical equivariant BV observable is a classical equivariant BV observable that is closed under $Q_{\text{cBV}}$.

Lemma 3.4. The ideal $\mathcal{I}_T'$ in $\mathcal{N}_T'$ generated by $T$ is a $\Delta_{S,T}$-invariant Poisson ideal.

Proof. Let $OT \in \mathcal{I}_T'$ and $U \in \mathcal{N}_T'$. We then compute

$$\{U, OT\} = \{U, O\} T \pm O \{U, T\} = \{U, O\} T,$$

where $\{U, T\} = \{U, T'\} = 0$ since $U \in \mathcal{N}_T'$. Moreover, $\{U, O\} \in \mathcal{N}_T'$ since $U, O \in \mathcal{N}_T'$ and Proposition 3.1 so that $\{U, OT\} \in \mathcal{I}_T'$. We then see that

$$\Delta_{S,T}(OT) = (\Delta_{S,T}O) T \pm \{O, T\} = (\Delta_{S,T}O) T,$$

as a consequence of (6). Finally, as a consequence of points $iv)$ of Lemmata 3.2 and 3.3 we check that $\Delta_{S,T}O \in \mathcal{N}_T'$ so that $\mathcal{I}_T'$ is $\Delta_{S,T}$-invariant. □

We define the algebra of quantum equivariant preobservables as $\mathcal{A}_T = \mathcal{N}_T'/\mathcal{I}_T'$ with its induced differential:

$$\Delta_{S,T}[O] := \Delta_{S,T}O = \left[\left(\Delta + \frac{i}{\hbar} Q_{\text{BV}}\right) O\right].$$

A quantum equivariant observable is an equivariant preobservable which is $\Delta_{S,T}$ closed, for instance the equivalence class of the constant functional.

It is customary to regularize $\Delta S_{\text{eva}}$ and $\Delta S_0$ as zero, see the comment after (13). Moreover, one may also often assume $\Delta S_0 = 0$ (for instance this is the case for the Poisson Sigma Model with unimodular Poisson structure, see [6]). In this case, we have

$$T = T' = T_0 = -u^a S_{\text{eva}}$$
and
\[ N'_T = \{ \mathcal{O} \in \mathcal{A}[u], \mathcal{L}_X \mathcal{O} = 0 \ \forall X \in \mathfrak{g} \} = \mathcal{A}[u]^0. \]

Remark that the complex \((\mathcal{A}[u]^0, Q^{\mathcal{C}}_{BV})\) is the Cartan model for the equivariant cohomology of the \(\mathfrak{g}\)-differential algebra \(\mathcal{A} = C(\mathcal{F}_\Sigma)\).

Finally, let us discuss gauge fixing when the target manifold \(\mathcal{M}\) is a graded vector space \(V\), so that the space of BV fields is \(\mathcal{F}_\Sigma = \Omega \Sigma \otimes V\). Let us introduce an invariant metric on \(\Sigma\) and let us define \(\mathcal{L} = \Omega^{\omega}(\Sigma) \otimes V\), where \(\Omega^{\omega}(\Sigma)\) stands for coexact forms. In general, due to harmonic forms of \(\Sigma\), \(\mathcal{L}\) is only isotropic, but let us ignore this issue at the present level of discussion. Since the invariance of the metric implies that \([L_{v_X}, d]\) = 0, we have that \(S_{L_{v_X}}|_{\mathcal{L}} = 0\). The characteristic foliation defined by \(\{T, -\}\) coincides with the infinitesimal \(\mathfrak{g}\)-action so that we have to require that \(G\) is compact (see the discussion in Remark 2.1).

**Remark 3.5.** Some instances of the construction of this paper have appeared before. For example, in [7] an \(S^1\)-equivariant version of the Poisson sigma model on a disk is studied. The equivariant extension of the BV action is hinted at in Example 2 and an invariant gauge fixing is behind the choice of propagator of Section 5.3. The whole Feynman diagram expansion, which is at the core of the paper, is the one corresponding to the equivariant BV theory. Another example is Getzler’s paper [9] where the special case of classical BV-equivariance under source diffeomorphisms for one-dimensional systems is considered. To the best of our knowledge the first discussion about the relation between BV formalism and equivariant localization can be found in [14].

### 4. Equivariant Two Dimensional SYM

We discuss here the equivariant extension of two dimensional supersymmetric Yang-Mills theory; we use version of the AKSZ approach developed in [5].

Let \(\Sigma_2\) be a two dimensional closed manifold\(^1\) and \(\mathfrak{g}\) a Lie algebra acting on it. Let us consider the AKSZ theory with target \(T^*[1](\mathfrak{k}[1] \times \mathfrak{k}[2])\), where \(\mathfrak{k}\) is a Lie algebra (not to be confused with \(\mathfrak{g}\)). The index \(\alpha\) appearing in the following formulas runs over a basis of \(\mathfrak{k}\) and \(a\) over a basis of \(\mathfrak{g}\). If \(c, \phi\) are the Lie algebra coordinates of \(\mathfrak{k}\) of degree 1, 2

---

\(^1\)We may relax this condition if we can guarantee that Stokes theorem works by imposing the appropriate boundary conditions or appropriate decay at infinity. This comment is applicable to AKSZ construction in general.
respectively and \( \xi, \tilde{\xi} \) the momenta of degree 0, \(-1\) respectively, then the homological Hamiltonian reads
\[
\Theta = \frac{1}{2} \xi\alpha [c, c] + \xi\alpha [c, \phi] + \xi\phi \phi\alpha ,
\]
so that \( D(\cdot) = \{ \Theta, \cdot \} \) reads:
\[
\begin{align*}
Dc &= \phi + \frac{1}{2} [c, c] , \\
D\phi &= [c, \phi] , \\
D\xi &= [c, \xi] - [\phi, \tilde{\xi}] , \\
D\tilde{\xi} &= \xi + [c, \tilde{\xi}] .
\end{align*}
\]

The superfields read
\[
\begin{align*}
c &= c + A + \xi\nu , & \Xi &= \xi + A\nu + c\nu , \\
\Phi &= \phi + \psi + \tilde{\xi}\nu , & \tilde{\Xi} &= \tilde{\xi} + \psi\nu + \phi\nu .
\end{align*}
\]

The equivariant AKSZ action in the Cartan model is
\[
S_{BV} = \int_{T[1]\Sigma_2} \Xi\alpha \Phi^\alpha + \frac{1}{2} \xi\alpha [c, c] + \frac{1}{2} \xi\alpha [\Phi, c] + \xi\alpha d_G c^\alpha + \tilde{\Xi}\alpha d_G \Phi^\alpha
\]
where \( d_G = d_\Sigma - u^a t_{va} \) is the equivariant differential. We compute the equivariant extension of the BV differential in the Cartan model as
\[
\begin{align*}
Q_{BV}(A) &= \psi' + d_A c , \\
Q_{BV}(\psi') &= + d_A \phi + [c, \psi'] + u^a t_{va} F(A) , \\
Q_{BV}(\phi) &= [c, \phi] - u^a t_{va} \psi' , \\
Q_{BV}(c) &= \phi + \frac{1}{2} [c, c] - u^a t_{va} A , \\
Q_{BV}(H) &= [c, H] - [\phi, \tilde{\xi}] + u^a t_{va} d_A \xi , \\
Q_{BV}(\tilde{\xi}) &= H + [c, \tilde{\xi}] ,
\end{align*}
\]
where \( \psi' = \psi - u^a t_{va} \xi' \), \( H = \xi - u^a t_{va} \psi' \) and \( d_A = d_\Sigma + [A, -] \). As explained in Section 5.2 of [5] for the non equivariant case, the AKSZ fields do not contain the full supersymmetric multiplet. The fields needed to recover the supercharge of the topologically twisted \( N = 2 \) supersymmetric gauge theory in the so called \( \Omega \)-background will appear in the gauge fixing procedure.

Let us fix an arbitrary invariant metric on \( \Sigma_2 \). We consider the standard gauge fixing Lagrangian defined by coexact forms (zero modes given by cohomology can be ignored for what concerns the present discussion). The two-form fields are then put to zero, \( i.e. \xi' = \tilde{\xi}' = \)
\(c^\vee = \phi^\vee = 0\); in order to fix the one-form fields \(A\) and \(\psi\) we add two sets of equivariant trivial pairs \(\{\bar{c}, b\}\) and \(\{\lambda, \rho\}\), respectively.

Namely the first one is given by \(\lambda, \rho \in \Omega^0(\Sigma_2; \mathfrak{t})\) of ghost number \(-2\) and \(-1\) respectively with momenta \(\lambda^\vee, \rho^\vee \in \Omega^2(\Sigma_2; \mathfrak{t}^*)\) of ghost degree 1 and 0. The second one is given by \(\bar{c}, b \in \Omega^0(\Sigma_2, \mathfrak{k})\) of degree \(-1, 0\) respectively, with momenta \(\bar{c}^\vee, b^\vee \in \Omega^2(\Sigma_2, \mathfrak{k}^*)\) of degree 0, \(-1\).

The gauge fixing fermion is defined as

\[\Psi = \int_{T[1]\Sigma_2} \lambda \ d\Sigma * \psi + \bar{c} \ d\Sigma * A.\]

The Lie algebra \(\mathfrak{g}\) acts in the direction of the trivial pair with Hamiltonians

\[S^c_{\mathfrak{L}a} = \int_{T[1]\Sigma_2} \rho^\vee_\alpha L_{va} \lambda^\alpha + b^\vee_\alpha L_{va} \bar{c}^\alpha,\]
\[S^r_{\mathfrak{L}a} = \int_{T[1]\Sigma_2} \lambda^\vee_\alpha L_{va} \lambda^\alpha + \rho^\vee_\alpha L_{va} \rho^\alpha + \bar{c}^\vee_\alpha L_{va} \bar{c}^\alpha + b^\vee_\alpha L_{va} b^\alpha.\]

The BV action (23) will be shifted by a term

\[S^c_{\mathfrak{tr}} = \int_{T[1]\Sigma_2} \lambda^\vee_\alpha \rho^\alpha + \bar{c}^\vee_\alpha b^\alpha - u^a \int_{T[1]\Sigma_2} \rho^\vee_\alpha L_{va} \lambda^\alpha + b^\vee_\alpha L_{va} \bar{c}^\alpha.\]

The BV transformations of the trivial pair \((\lambda, \rho)\) then read

\[Q^c_{\mathfrak{BV}}(\lambda) = \zeta + [c, \lambda],\]
\[Q^c_{\mathfrak{BV}}(\zeta) = -[\phi, \lambda] + [c, \zeta] + u^a L_{va} d_\lambda,\]

where \(\zeta = \rho - [c, \lambda]\). By a direct comparison, one can check that \(Q^c_{\mathfrak{BV}}\) restricted to the multiplet \(\{A, \phi, \psi', H, \xi, \lambda, \zeta\}\) acts as

\[Q^c_{\mathfrak{BV}} = \delta_{\mathfrak{BRST}} + \delta_{\mathfrak{susy}},\]

where \(\delta_{\mathfrak{susy}}\) is the supercharge in [13] and \(\delta_{\mathfrak{BRST}}\) the usual BRST operator.

**Remark 4.1.** In [5] the susy multiplet was recovered with a slightly different procedure. Indeed, the trivial pair \((\lambda, \rho)\) appeared with an ad hoc procedure, without performing the actual gauge fixing. In this way we missed the fact they appear in the standard gauge fixing procedure as the antighost and Lagrange multiplier needed for imposing the gauge fixing condition \(d * \psi = 0\).

Let us now discuss the classical equivariant BV observables. Following [5] we look for a map \(\text{ev} : \mathcal{F}_{\Sigma_2} \otimes T[1]\Sigma_2 \to T[1]\mathfrak{k}[1]\) such that for each \(\omega \in C(T[1]\mathfrak{k}[1])\)

\[ (Q^c_{\mathfrak{BV}} - d_\Sigma + u^a L_{va}) \text{ev}^* \omega = \text{ev}^* D\omega.\]
A straightforward computation shows that
\begin{equation}
\text{ev}^*(c) = c + A, \text{ev}^*(\phi) = \phi + \psi' - F(A)
\end{equation}
satisfies (26). From (27) we see that
\begin{equation}
(\hat{L}_{vu} + L_u - L_{vu}) \text{ev}^* \omega = 0.
\end{equation}

Let now $D \omega = 0$ and let $\gamma[u] \in (C \otimes Sg^\ast)^0$ be an equivariant cycle as discussed at the end of Appendix A; we define $O_{\omega}^\gamma \equiv \int_{\gamma[u]} \text{ev}^* \omega$. From (26) we see that
\begin{equation}
Q_{\text{BV}}^\gamma O_{\omega}^\gamma = \int_{\gamma[u]} (d_\Sigma - u^a \iota_{v_a}) \text{ev}^* \omega = \int_{\partial_G \gamma[u]} \text{ev}^* \omega = 0.
\end{equation}
Moreover, from (27) it follows that
\begin{equation}
L_u O_{\omega}^\gamma = (\hat{L}_{vu} + L_u) O_{\omega}^\gamma = -\int_{\gamma[u]} L_{vu} \text{ev}^* \omega = \int_{L_{vu} \gamma[u]} \text{ev}^* \omega = 0,
\end{equation}
so that $O_{\omega}^\gamma \in \mathcal{A}[u]^g$ is an equivariant classical BV observable.

5. Equivariant Donaldson-Witten theory

We analyze here the AKSZ approach to Donaldson-Witten theory \cite{17}. We start with a discussion of the non equivariant case. Our derivation will differ from \cite{10} in the gauge fixing procedure.

5.1. DW from AKSZ. Let $\mathfrak{k}$ be a Lie algebra. In the previous section we could use the Weil model $W(\mathfrak{k})$ as the target of a 2d AKSZ model only after embedding it in the bigger dGA (21) that has a natural symplectic form of degree 1. If $\mathfrak{k}$ admits an invariant non degenerate symmetric pairing $\langle \ , \ \rangle$, then $W(\mathfrak{k})$ admits a natural symplectic form of degree 3 and can be used as a target of a 4d AKSZ theory.

Indeed the graded vector space
\begin{equation}
\mathfrak{k}[1] \oplus \mathfrak{k}[2]
\end{equation}
is equipped with the symplectic structure of degree 3
\begin{equation}
\omega = \langle \delta c, \delta \phi \rangle,
\end{equation}
where $c$ is the coordinate of degree 1 and $\phi$ is the coordinate of degree 2. The Hamiltonian function of degree 4
\begin{equation}
\Theta = \frac{1}{2} \langle \phi, \phi \rangle + \frac{1}{2} \langle \phi, [c, c] \rangle,
\end{equation}
has the Weil differential as Hamiltonian vector field
\begin{equation}
d_W c = \phi + \frac{1}{2} [c, c],
\end{equation}
\begin{equation}
d_W \phi = [c, \phi].
\end{equation}
Let us consider now the 4D AKSZ model with this target and source the four dimensional manifold $\Sigma_4$. The superfields read

\begin{align}
\mathbf{c} &= c + A + \chi + \psi^\vee + \phi^\vee, \\
\Phi &= \phi + \psi + \chi^\vee + A^\vee + c^\vee.
\end{align}

The BV symplectic form is

\begin{equation}
\omega_{BV} = \int_{T[1]\Sigma_4} d^4x d^4\theta \langle \delta \mathbf{c}, \delta \Phi \rangle
\end{equation}

and the AKSZ action is

\begin{equation}
S_{BV} = \int_{T[1]\Sigma_4} \left( \langle \Phi, d_\Sigma \mathbf{c} \rangle + \frac{1}{2} \langle \Phi, \Phi \rangle + \frac{1}{2} \langle \Phi, [\mathbf{c}, \mathbf{c}] \rangle \right).
\end{equation}

In terms of the components, the BV symplectic structure can be written as follows

\begin{equation}
\omega_{BV} = \int_{\Sigma_4} (\delta c \wedge \delta c^\vee + \delta A \wedge \delta A^\vee + \delta \chi \wedge \delta \chi^\vee + \delta \psi^\vee \wedge \delta \psi + \delta \phi^\vee \wedge \delta \phi).
\end{equation}

The BV action in components reads

\begin{equation}
S_{BV} = \int_{\Sigma_4} \left( \langle \psi, dA \chi \rangle + \frac{1}{2} \langle \phi, [\chi, \chi] \rangle + \langle \psi^\vee, (dA \phi + [c, \psi]) \rangle + \langle \chi^\vee, (F + [c, \chi]) \rangle + \langle A^\vee, (\psi + dA c) \rangle + \langle \phi^\vee, [c, \phi] \rangle + \langle c^\vee, (\phi + \frac{1}{2} [c, c]) \rangle + \frac{1}{2} \langle \chi^\vee, \chi^\vee \rangle \right).
\end{equation}

**Remark 5.1.** The linear terms in anti-fields give us familiar BRST-transformations of the fields. The quadratic term in anti-fields is telling us that they close only on-shell. It can be fixed by introducing the couple of two forms $(H, H^\vee)$, even and odd correspondently with $\deg H = 0$ and $\deg H^\vee = -1$. The last quadratic term in the action can be replaced as follows

\begin{equation}
\frac{1}{2} \langle \chi^\vee, \chi^\vee \rangle \to -\langle \chi^\vee, H \rangle - \frac{1}{2} \langle H, H \rangle.
\end{equation}

In this way we get an action linear in anti-fields and this is just canonical embedding of DW BRST-transformations into BV.

The BV transformations on the superfields are

\begin{align}
Q_{BV} \mathbf{c} &= d_\Sigma \mathbf{c} + \Phi + \frac{1}{2} [\mathbf{c}, \mathbf{c}] , \\
Q_{BV} \Phi &= d_\Sigma \Phi + [\mathbf{c}, \Phi],
\end{align}
EQUIVARIANT BATALIN-VILKOVISKY FORMALISM

and on the components become

\[
Q_{BV} c = \phi + \frac{1}{2} [c, c],
Q_{BV} A = \psi + d_A c,
Q_{BV} \chi = \chi^\vee + F(A) + [c, \chi],
Q_{BV} \psi^\vee = d_A \chi + A^\vee + [c, \psi^\vee],
Q_{BV} \phi^\vee = d_A \psi^\vee + c^\vee + [c, \phi^\vee],
Q_{BV} \phi = [c, \phi],
Q_{BV} \psi = d_A \phi + [c, \psi],
Q_{BV} \chi^\vee = d_A \psi + [c, \chi^\vee] + [\chi, \phi],
Q_{BV} A^\vee = d_A \chi^\vee + [c, A^\vee] + [\psi^\vee, \phi] + [\chi, \psi],
Q_{BV} \psi^\vee = d_A \chi^\vee + [c, \psi^\vee] + [\phi^\vee, \phi] + [\psi^\vee, \psi] + [\chi, \chi^\vee],
\]

(38)

where \( d_A = d_{\Sigma} + [A, \cdot] \) and \( F(A) = d_{\Sigma} A + \frac{1}{2} [A, A] \).

Let us now discuss the gauge fixing. Let us introduce a metric on \( \Sigma_4 \); we split the two-forms into self-dual and anti-self-dual components

\[
\chi = \chi^\vee + \chi^-, \quad \chi^\vee = \chi^{\vee -} + \chi^{\vee +}.
\]

(39)

As gauge fixing we impose \( \chi^- = 0 \) and \( \chi^\vee = 0 \) and we require that the other forms are co-exact. Co-exactness in sectors \( (c, c^\vee) \) and \( (\phi, \phi^\vee) \) implies that \( c^{\vee} = 0 \) and \( \phi^\vee = 0 \). To impose the co-exactness in sectors \( (A, A^\vee) \) and \( (\psi, \psi^\vee) \) we use the standard procedure of introducing extra trivial sectors. To impose the co-exactness on \( (A, A^\vee) \) we introduce zero forms \((\bar{c}, b)\) with deg \( \bar{c} = -1 \), deg \( b = 0 \) and their antifields \((\bar{c}^\vee, b^\vee)\) which are top forms with deg \( \bar{c}^\vee = 0 \) and deg \( b^\vee = -1 \). To the BV action (34) we can add the following terms of degree zero

\[
S_{tr,1} = \int \left( \langle \bar{c}^{\vee}, (b + [c, \bar{c}]) \rangle + \langle b^{\vee}, ([c, b] - [\phi, \bar{c}]) \rangle \right).
\]

(40)

With this choice, \( b \) and \( \bar{c} \) transform correctly under the gauge transformations. It is easy to check that the standard BV trivial pair is recovered by a simple field redefinition. Now we have to repeat the same trick for \((\psi, \psi^\vee)\) sector. Let us introduce zero forms \((\varphi, \eta)\) with degrees deg \( \varphi = -2 \), deg \( \eta = -1 \) and their top forms anti-fields \((\varphi^\vee, \eta^\vee)\) with deg \( \varphi^\vee = 1 \), deg \( \eta^\vee = 0 \). To the BV action we add the following term of degree zero

\[
S_{tr,2} = \int \left( \langle \varphi^{\vee}, (\eta + [c, \varphi]) \rangle + \langle \eta^{\vee}, ([c, \eta] + [\varphi, \phi]) \rangle \right).
\]

(41)
Finally

\[ S'_{BV} = S_{BV} + S_{tr,1} + S_{tr,2} \]

satisfies the master equation. The gauge fixing fermions will be

\[ \Psi = \int \langle \bar{c}, d \star A \rangle + \int \langle \varphi, d \star \psi \rangle. \]  

(42)

After the gauge fixing we get the following residual gauge transformations

\[ \begin{align*}
\delta c &= \phi + \frac{1}{2} [c, c], \\
\delta A &= \psi + d_A c, \\
\delta \chi^+ &= F^+ + [c, \chi^+], \\
\delta \phi &= [c, \phi], \\
\delta \psi &= d_A \phi + [c, \psi], \\
\delta \chi^{-\vee} &= d_A \psi + [c, \chi^{-\vee}], \\
\delta \bar{c} &= b + [c, \bar{c}], \\
\delta b &= [c, b] - [\phi, \bar{c}], \\
\delta \varphi &= \eta + [c, \varphi], \\
\delta \eta &= [c, \eta] + [\varphi, \phi].
\end{align*} \]

(43)

Here the bosonic field \( \chi^{-\vee} \) is auxiliary field of degree 0 and it can be integrated out. The above transformations square to zero except for \( \chi^+ \)

\[ \delta^2 \chi^+ = (d_A \psi)^+ + [\phi, \chi^+] , \]

(44)

which is equation of motion. Actually this is easily seen from the full BV action (35) which has linear and quadratic terms in anti-fields. It is clear that the multiplet \( (A, \phi, \psi, \chi^+, \varphi, \eta) \) reproduces the vector multiplet appearing in [17].

5.2. Equivariant DW theory. Let us now consider that the Lie algebra \( g \) acts on \( \Sigma_4 \) with vector fields \( v_X, X \in g \). The equivariant extension is obtained by replacing \( d_{\Sigma} \) by \( d_G = d_{\Sigma} - u^a \iota_{v_a} \) in the AKSZ action.

\[ S_{BV}^c = \int_{T[1]\Sigma_4} \left( \langle \Phi, d_G c \rangle + \frac{1}{2} \langle \Phi, \Phi \rangle + \frac{1}{2} \langle \Phi, [c, c] \rangle \right) . \]

(45)

\[ = S_{BV} - u^a \int \left( \psi \iota_{v_a} \phi^\vee + \chi^\vee \iota_{v_a} \psi^\vee + A^\vee \iota_{v_a} \chi + c^\vee \iota_{v_a} A \right) . \]
The BV transformations are

\[ Q_{BV}^c c = d_G c + \Phi + \frac{1}{2} [c, c] , \]

\[ Q_{BV}^c \Phi = d_G \Phi + [c, \Phi] . \]

which in components are written as (we list only relevant fields)

\[ Q_{BV}^c c = \phi + \frac{1}{2} [c, c] - u^a \iota_{v_a} A , \]

\[ Q_{BV}^c A = \psi + d_A c - u^a \iota_{v_a} \chi , \]

\[ Q_{BV}^c \chi = \chi^\vee + F + [c, \chi] - u^a \iota_{v_a} \psi^\vee , \]

\[ Q_{BV}^c \phi = [c, \phi] - u^a \iota_{v_a} \psi , \]

\[ Q_{BV}^c \psi = d_A \phi + [c, \psi] - u^a \iota_{v_a} \chi^\vee . \]

The procedure of gauge fixing can be done in the same way of the non equivariant case, provided we choose an invariant metric on \( \Sigma_4 \).

The solution of the equivariant master equation is now

\[ S_{BV}^{c'} = S_{BV}^c + \int \left( \langle \bar{c}^\vee, (b + [c, \bar{c}]) \rangle + \langle b^\vee, (L_v \bar{c} + [c, b] - [\phi, \bar{c}]) \rangle \right) \]

\[ + \int \left( \langle \varphi^\vee, (\eta + [c, \varphi]) \rangle + \langle \eta^\vee, (L_v \varphi + [c, \eta] + [\varphi, \phi]) \rangle \right) . \]

As before the we impose \( \chi^- = 0 \) and \( \chi^{\vee+} = 0 \) and for the other fields we choose the fermionic gauge fixing \( [12] \).

To match with the standard gauge theory we need to do some field redefinitions, e.g. \( \tilde{\psi} = \iota_v \chi + \psi \) etc. One can immediately recognize the transformations for the equivariant Donaldson-Witten theory (also known as topologically twisted \( N = 2 \) supersymmetric gauge theory in \( \Omega \)-background) \[11\] [12].

Let us point out that the present 4D equivariant AKSZ construction can be generalized in different directions. For example we can adopt alternative decomposition \( [39] \) of the two-forms into self-dual and anti-self dual parts following ideas presented in \[8\]. This will lead to alternative gauge fixing and the resulting theory corresponds to cohomological theory which appeared in the Pestun’s localization calculation \[15\] (see \[8\] for the corresponding cohomological description).

**APPENDIX A. EQUIVARIANT COHOMOLOGY AND HOMOLOGY**

Let \( \mathfrak{g} \) be a Lie algebra. A \( \mathfrak{g} \)-differential algebra \( \mathcal{A} \) is a differential graded algebra \( (\mathcal{A}, d) \) with \( L_X \in \text{Der}^0 \mathcal{A} \) and \( \iota_X \in \text{Der}^{-1} \mathcal{A} \), depending linearly on \( X \in \mathfrak{g} \) and satisfying the rules of Cartan’s calculus:

\[ [L_X, d] = 0 , \quad [L_X, L_Y] = L_{[X,Y]} , \quad [\iota_X, d] = L_X , \quad [\iota_X, \iota_Y] = 0 , \quad [\iota_X, L_Y] = \iota_{[X,Y]} \]
The basic subalgebra is defined as \( A_{bas} = \{ a \in A, L_X a = \iota_X a = 0, \forall X \in \mathfrak{g} \} \).

Let \( \{ t_a \} \) be a basis of \( \mathfrak{g} \). We denote with \( W(\mathfrak{g}) = (A^* \otimes S(\mathfrak{g}^*), d_W) \) the Weil \( \mathfrak{g} \)-differential algebra defined as

\[
\begin{align*}
    d_W \theta^a &= u^a + \frac{1}{2} [\theta, \theta]^a \\
    d_W u^a &= [\theta, u]^a 
\end{align*}
\] (50) (51)

where \( \deg \theta = 1 \) and \( \deg u = 2 \) and \( \iota_a = \frac{\partial}{\partial \theta^a} \) and \( L_a = \{ \iota_a, d_W \} \).

The complex \((W(\mathfrak{g}), d_W)\) is acyclic; the basic subcomplex is given by \( C(\mathfrak{g}) \) the invariant polynomials in \( u \) with the restriction of \( d_W \) to the basic subcomplex.

We can define on \( A \otimes W(\mathfrak{g}) \) the obvious tensor product structure of \( \mathfrak{g} \)-differential algebra. We denote with \( H_G(A) \) the cohomology of the basic subcomplex \( A_G = (A \otimes W(\mathfrak{g}))_{basic}, \) that is called the Weil model for \( H_G(A) \).

We can also consider the graded algebra \( A[u] = A \otimes S(\mathfrak{g}^*) \) equipped with \( d_G = d - u^a \iota_{v_a} \) and the diagonal \( \mathfrak{g} \)-action. Since \( d_G^2 = u^a L_{v_a} \), then \( (A[u]^\mathfrak{g}, d_G) \) where \( A[u]^\mathfrak{g} = \{ A \in A[u] | L_X A = 0, \forall X \in \mathfrak{g} \} \), is a dg algebra. We call it the Cartan model for \( H_G(A) \). In order to prove that its cohomology is isomorphic to \( H_G(A) \) it is enough to check that

\[
I = \exp [-(\iota_{v_a} \otimes \theta^a)] : A \otimes W(\mathfrak{g}) \to A \otimes W(\mathfrak{g})
\] (52)

restricts to an isomorphism of dg-algebras \( I : A_G \to (A[u])^\mathfrak{g} \).

Let \( \mathfrak{g} \) act on the smooth manifold \( \Sigma \); the dg algebra of forms \( (\Omega(\Sigma), d_\Sigma) \) is a \( \mathfrak{g} \)-differential algebra with \( L_{v_X}, \iota_{v_X} \) being the Lie derivative and contraction by the fundamental vector field \( v_X \) of \( X \in \mathfrak{g} \). We denote with \( H_G(\Sigma) \) the \( G \)-equivariant cohomology. In particular we have that \( H_G(\Sigma)^* = S(\mathfrak{g}^*)^\mathfrak{g} \).

Let \((C^*(\Sigma), \partial)\) denote the complex of de Rham currents where \( C^k(\Sigma) = (\Omega^{n-k}(\Sigma))^* \) and the differential is defined by duality. By duality \((C^*(\Sigma), \partial)\) inherits the structure of \( \mathfrak{g} \)-differential algebra. We can then define the Cartan model \( (C(\Sigma) \otimes S(\mathfrak{g}^*)^\mathfrak{g} \) and the Weil model \( (C(\Sigma) \otimes W(\mathfrak{g}))_{basic}; \) we call their cohomology the equivariant homology of \( \Sigma \).
