MINNAERT RESONANCES FOR BUBBLES IN SOFT ELASTIC MATERIALS

HONGJIE LI, HONGYU LIU, AND JUN ZOU

ABSTRACT. Minnaert resonance is a well known physical phenomenon and it has many important applications, in particular in the effective realisation of acoustic metamaterials using bubbly mediums in recent years. In this paper, motivated by the Minnaert resonance, we consider the low-frequency resonance for acoustic bubbles embedded in soft elastic materials. This is a hybrid physical process that couples the acoustic and elastic wave propagations. By delicately and subtly balancing the acoustic and elastic parameters as well as the geometry of the bubble, we show that Minnaert resonance can (approximately) occur for rather general constructions. Our study poses a great potential for the effective realisation of negative elastic materials by using bubbly elastic mediums.

Keywords: Minnaert resonance, bubbly elastic medium, hybrid Neumann-Poincaré operator, spectral, negative elastic materials.

2010 Mathematics Subject Classification: 74F10, 74B99, 74J20, 47G40

1. Introduction

The oscillation of bubbles in mediums is a classical problem. In particular, when bubbles are immersed in liquids, even a very small volume fraction of bubbles can have significant influences on the effective velocity of waves in liquids [10, 19]. This is due to the high oscillation of the bubbles caused by the high contrast in density between the bubbles and the surrounding liquid [1, 18]. In fact, at a particular low frequency known as the Minnaert resonant frequency, the bubbles can be treated as acoustic resonators [25]. The exceptional acoustic properties mentioned above can have many important applications and in particular can be used to the design of new materials, such as phononic crystals. In addition to many experimental progresses, the bubbly acoustic materials have been systematically and comprehensively investigated recently in the mathematical literature. Furthermore, based on the mathematical theory developed, novel applications were also proposed, especially for the effective realisation of acoustic metamaterials. For the case that a single bubble is immersed in liquids, the authors in [1] provide a rigorous treatment of the Minnaert resonance and the monopole approximation. Later, they investigate the acoustic scattering by a large number of bubbles in liquids at frequencies near the Minnaert resonant frequency in [2]. Thus by designing bubble metascreens, the superabsorption effect can be achieved [3]. Around the Minnaert resonant frequency, an effective medium theory is derived in [8]. Moreover, the opening of a sub-wavelength phononic bandgap is demonstrated by considering a periodic arrangement of bubbles and exploiting the corresponding Minnaert resonance in [4].

Nevertheless, as pointed out in [20, 29], the practical constructions of acoustic bubbly designs are very challenging. The major difficulty arises from making bubbles to have a uniform size and letting them remain inside the liquids. In order to overcome those challenges, substituting the host medium from liquids to soft elastic materials (the shear
modulus is small) becomes a more practical scheme. In fact, the oscillation of a spherical cavity in an elastic material has been investigated many years ago [26]. When a spherical bubble is immersed in a soft elastic material, it is shown in [11] that there also exists a certain low-frequency resonance. Using such resonant properties, the bubbly elastic structures have been used to the experimental design of new materials for strikingly new applications. For examples, bubble phononic crystals are designed in [20], super-absorption of acoustic waves with bubble metascreens is achieved in [21] and reducing underwater sound transmission is shown in [12] by microfabricating cavities into silicone rubber (a soft elastic material).

Motivated by the aforementioned physical and mathematical studies, in this paper, we consider the low-frequency resonance for the case where a bubble is embedded in a soft elastic medium. We aim to derive a systematic and comprehensive mathematical understanding of the resonance phenomena caused by the acoustic and elastic interactions. It turns out that the mathematical investigation on the resonance associated with the elastic bubbly mediums is more challenging than that for the acoustic bubbly mediums. Indeed, we note that first, the wave scattering from an elastic bubbly medium is a hybrid physical process which couples the acoustic wave propagation inside the bubble and the elastic wave propagation outside the bubble. Second, since the shear modulus in the elastic material is non-zero, thus the resonance heavily depends on the geometry of the bubble [11]. This property is in a sharp contrast to the case of bubbles in liquids which features weak shape dependence [1]. Therefore one can not expect an explicit expression of the resonant frequencies (unless the geometry of the bubble is simple, say, a radial one) as the case for bubbles in liquids that was derived in [1]. Third, the bubble-liquid resonance only depends on the high contrast of the density between the bubble and the liquid. However, for the bubble-elastic material resonance, in addition to the high contrast of the density, the high contrast of the shear modulus and the compression modulus is required; see also [28] for a related discussion.

According to our discussion above, it is clear that the bubble-elastic resonance is of a different physical nature to the bubble-liquid resonance. Nevertheless, in order to reveal its origin of motivation as well as for the terminological convenience, we still call it the Minnaert resonance in the present paper. In order to derive the resonance results, following the spirit of the mathematical treatment in [1], we rely on the layer-potential techniques, which boil down our study to the asymptotic and spectral analysis of the layer-potential operators involved for the coupled PDE systems. By delicately and subtly balancing the acoustic and elastic parameters as well as the geometry of the bubble, we show that Minnaert resonance can (approximately) occur for a rather general construction in the three-dimensional case. In the two-dimensional case, due to the technical constraint, we can only deal with the case that the bubble is in the radial geometry. Moreover, as also mentioned earlier, we only consider the case with a single bubble embedded in a soft elastic material. We shall study the other case, e.g., the scattering from multiple bubbles, in our forthcoming work. It is emphasized that similar to the bubble-liquid case, our study poses a great potential for the effective realisation of negative elastic materials by using bubbly elastic mediums, which we shall also investigate in our near-future study.

The rest of the paper is organized as follows. In Section 2, we present the general mathematical formulation of our study, especially the acoustic-elastic wave scattering from an bubble-elastic structure and its integral reformulation. In Section 3, we discuss
about the general requirements on the medium configuration and also derive some auxiliary results for the subsequent use. Sections 4 and 5 are respectively devoted to the Minnaert resonances in three and two dimensions. Our study is concluded in Section 6 with some related remarks.

2. Mathematical setup

In this section, we represent the general mathematical formulation of our study. Let \( D \) be a bounded domain in \( \mathbb{R}^N \), \( N = 2, 3 \), with a \( C^2 \)-regular boundary \( \partial D \). \( D \) denotes the air bubble in our study. Let \( \rho, \mu \in \mathbb{R}_+ \) and \( k \in \mathbb{R}_+ \) signify the density and the bulk modulus of the air inside the bubble, respectively. Assume that the background \( \mathbb{R}^N \setminus \overline{\mathcal{D}} \) is occupied by a regular and isotropic elastic material parameterized by the Lamé constants \((\lambda, \mu)\) satisfying the following strong convexity conditions

\[
\begin{align*}
\text{i)} & \quad \mu > 0 \quad \text{and} \quad \text{ii)} \quad N\lambda + 2\mu > 0.
\end{align*}
\]

The density of the background material is set to be \( \rho_k \in \mathbb{R}_+ \). Let \( u \) be a incident elastic wave, which is an entire solution to

\[
\mathcal{L}_{\lambda, \mu} u + \omega^2 \rho_k u = 0 \quad \text{in} \quad \mathbb{R}^N.
\]

Here, \( \omega \in \mathbb{R}_+ \) denotes the frequency of the elastic wave. The acoustic-elastic wave interaction is described by the following coupled PDE system (cf. [27]),

\[
\begin{align*}
\mathcal{L}_{\lambda, \mu} u(x) + \omega^2 \rho_b u(x) &= 0 \quad &x \in \mathbb{R}^N \setminus \overline{\mathcal{D}}, \\
\triangle u(x) + k^2 u(x) &= 0 \quad &x \in D, \\
u(x) \cdot \nu - \frac{1}{\rho_b \omega^2} \nabla u(x) \cdot \nu &= 0 \quad &x \in \partial D, \\
\partial_\nu u(x) + u(x) \nu &= 0 \quad &x \in \partial D, \\
u(x) - u^{\text{in}}(x)
\end{align*}
\]

satisfies the radiation condition,

where \( u \) is the total elastic wave field outside the domain \( D \), \( u \) is the pressure inside the domain \( D \), \( \omega \in \mathbb{R}_+ \) is the angular frequency and \( k = \omega/c_b \) with \( c_b = \sqrt{\kappa/\rho_b} \) signifying the velocity of the wave in \( D \). In (2.2), the Lamé operator \( \mathcal{L}_{\lambda, \mu} \) and the co-normal derivative \( \partial_\nu \), associated with the parameters \((\lambda, \mu)\), are respectively defined by

\[
\mathcal{L}_{\lambda, \mu} w := \mu \Delta w + (\lambda + \mu) \nabla \nabla \cdot w,
\]

and

\[
\partial_\nu w = \tilde{\lambda} (\nabla \cdot w) \nu + 2 \tilde{\mu} (\nabla^s w) \nu.
\]

Here \( \nu \) represents the outward unit normal vector to \( \partial D \) and the operator \( \nabla^s \) is the symmetric gradient

\[
\nabla^s w := \frac{1}{2} (\nabla w + \nabla w^t),
\]

with \( \nabla w \) denoting the matrix \((\partial_i w_i)_{i,j=1}^N\) and the superscript \( t \) signifying the matrix transpose. In (2.2), the third condition denotes the continuity of the normal component of the displacement on the boundary \( \partial D \) and the fourth condition is the continuity of the stress across \( \partial D \). Moreover, the radiation condition in (2.2) designates the following condition as \( |x| \to +\infty \) (cf. [22]),

\[
\begin{align*}
(\nabla \times \nabla \times (u - u^{\text{in}}))(x) \times \frac{x}{|x|} - i k_b \nabla \times (u - u^{\text{in}})(x) &= O(|x|^{-2}), \\
\frac{x}{|x|} : (\nabla (\nabla \cdot (u - u^{\text{in}})))(x) - i k_b \nabla (u - u^{\text{in}})(x) &= O(|x|^{-2}),
\end{align*}
\]

(2.6)
where \( i = \sqrt{-1} \),

\[
\tilde{k}_s = \frac{\omega}{\epsilon_s} = \frac{\omega}{\sqrt{\mu/\rho_e}} \quad \text{and} \quad \tilde{k}_p = \frac{\omega}{\epsilon_p} = \frac{\omega}{\sqrt{(\lambda + 2\mu)/\rho_e}},
\]

(2.7)

with \( \tilde{\lambda} \) and \( \tilde{\mu} \) defined in (2.1).

Next we apply the potential theory to derive the integral representation of the solution to the system (2.2) and give the definition of the resonance. First, we introduce the potential operators for the Helmholtz system and Lamé system. Let \( G^k(x) \) be the fundamental solution of the operator \( \Delta + k^2 \), namely

\[
G^k(x) = \begin{cases} 
-\frac{i}{4}H_0^{(1)}(k|x|), & N = 2, \\
\frac{e^{ik|x|}}{4\pi|x|}, & N = 3,
\end{cases}
\]

(2.8)

where \( H_0^{(1)} \) is the zeroth-order Hankel function of the first kind. The single layer potential associated with the Helmholtz system is defined as follows

\[
S^k_{\partial D}[\varphi](x) = \int_{\partial D} G^k(x - y) \varphi(y) ds(y) \quad x \in \mathbb{R}^N,
\]

(2.9)

where \( \varphi(x) \in L^2(\partial D) \) and \( G^k(x) \) is given in (2.8). Then the conormal derivative of the single layer potential enjoys the following jump formula

\[
\nabla S^k_{\partial D}[\varphi] \cdot \nu(x) = \left( \pm \frac{1}{2} I + K^s_{\partial D} \right)[\varphi](x) \quad x \in \partial D,
\]

(2.10)

where

\[
K^s_{\partial D}[\varphi](x) = \text{p.v.} \int_{\partial D} \nabla_x G^k(x - y) \cdot \nu_y \varphi(y) ds(y) \quad x \in \partial D,
\]

which is also known as the Neumann-Poincaré operator associated with Helmholtz system. Moreover, we introduce the operator \( K^k_{\partial D} \) which is the \( L^2 \)-adjoint of the operator \( K^s_{\partial D} \), defined as follows

\[
K^k_{\partial D}[\varphi](x) = \text{p.v.} \int_{\partial D} \nabla_y G^k(x - y) \cdot \nu_x \varphi(y) ds(y) \quad x \in \partial D.
\]

In what follows, we denote by \( S_{\partial D,0} \), \( K^s_{\partial D,0} \) and \( K^k_{\partial D,0} \) for \( k = 0 \). We would like to point out that, the operators \( K^s_{\partial D,0} \) and \( K^k_{\partial D,0} \) in three dimensions have the following expressions

\[
K^s_{\partial D,0}[\varphi](x) = \int_{\partial D} \frac{(x - y, \nu_y)}{4\pi|x - y|^3} \varphi(y) ds(y) \quad x \in \partial D,
\]

\[
K^k_{\partial D,0}[\varphi](x) = \int_{\partial D} \frac{(y - x, \nu_y)}{4\pi|x - y|^3} \varphi(y) ds(y) \quad x \in \partial D.
\]

(2.11)

We refer to [2][23] for the mapping properties of the operators introduced above.

Next we introduce the potential operators for the Lamé system. The fundamental solution \( \Gamma^\omega = (\Gamma_j^\omega)_{j=1} \) for the operator \( \mathcal{L}_\lambda^2 + \rho_e \omega^2 \) can be decomposed into shear and pressure components (cf. [5]),

\[
\Gamma^\omega = \Gamma_s^\omega + \Gamma_p^\omega,
\]

(2.12)
where
\[ \Gamma^\omega_p = -\frac{1}{\rho_c\omega^2} \nabla \nabla G^{k_p} \quad \text{and} \quad \Gamma^\omega_s = \frac{1}{\rho_c\omega^2} (\tilde{k}_s^2 \mathbf{I} + \nabla \nabla) G^{k_s}, \]
with \( \mathbf{I} \) denoting the \( N \times N \) identity matrix, \( G^k \) given in (2.3), and \( \tilde{k}_s \) as well as \( \tilde{k}_p \) defined in (2.7). The single layer potential operator associated with the fundamental solution \( \Gamma^\omega \) is defined by
\[ S^\omega_{\partial D}[\varphi](x) = \int_{\partial D} \Gamma^\omega(x - y) \varphi(y) ds(y), \quad x \in \mathbb{R}^N, \quad (2.13) \]
for \( \varphi \in L^2(\partial D)^N \). On the boundary \( \partial D \), the conormal derivative of the single layer potential satisfies the following jump formula
\[ \frac{\partial S^\omega_{\partial D}[\varphi]}{\partial \nu} |_\pm(x) = \left( \pm \frac{1}{2} \mathbf{I} + (K^\omega_{\partial D})^* \right) [\varphi](x), \quad x \in \partial D, \quad (2.14) \]
where
\[ K^\omega_{\partial D} \varphi(x) = \text{p.v.} \int_{\partial D} \frac{\partial \Gamma^\omega}{\partial \nu}(x - y) \varphi(y) ds(y), \quad (2.15) \]
with the subscript \( \pm \) indicating the limits from outside and inside \( D \), respectively. The operator \( K^\omega_{\partial D} \) is called Neumann-Poincaré (N-P) operator for the Lamé system. In our subsequent analysis, we also need the following single layer potential operators respectively associated with the \( p \)-wave (pressure wave) and \( s \)-wave (shear wave),
\[ S^\omega_{\partial D}[\varphi](x) = \int_{\partial D} \Gamma^\omega_i(x - y) \varphi(y) ds(y), \quad x \in H^1(\mathbb{R}^N \setminus \overline{D})^N, \quad (2.16) \]
where \( \varphi(y) \in L^2(\partial D)^N \) and the kernel functions \( \Gamma^\omega_i, i = p, s \) are defined in (2.12). We refer to [5] for the mapping properties of the operators introduced above.

With the help of the potential operators introduced above, the solution to (2.2) can be represented by the following integral ansatz,
\[ u = \begin{cases} S^k_{\partial D}[\varphi_b](x), & x \in D, \\ S^s_{\partial D}[\varphi_e](x) + u^i, & x \in \mathbb{R}^N \setminus \overline{D}, \end{cases} \quad (2.17) \]
for some density functions \( \varphi_b \in L^2(\partial D) \) and \( \varphi_e \in L^2(\partial D)^N \). By matching the transmission conditions on the boundary \( \partial D \), along with the help of the jump formulas (2.10) and (2.11), it is verified by straightforward calculations that the density functions \( \varphi_b, \varphi_e \) satisfy the following system of boundary integral equations:
\[ \tilde{A}(\omega, \delta)[\Phi](x) = F(x), \quad x \in \partial D, \quad (2.18) \]
where
\[ \tilde{A}(\omega, \delta) = \begin{pmatrix} \frac{1}{\rho_c \omega^2} \left( -\frac{1}{2} + K^\omega_{\partial D} \right) & -\nu \cdot S^\omega_{\partial D} \\ \nu S^\omega_{\partial D} & \frac{1}{2} + (K^\omega_{\partial D})^* \end{pmatrix}, \quad \Phi = \begin{pmatrix} \varphi_b \\ \varphi_e \end{pmatrix} \quad \text{and} \quad F = \begin{pmatrix} \nu \cdot u^i \\ -\partial_\nu u^i \end{pmatrix}. \]

Then the Minnaert resonance of the system (2.2) is defined for all \( \omega \in \mathbb{C} \) such that the following equation holds,
\[ \tilde{A}(k, \delta)[\Phi](x) = 0, \quad (2.19) \]
for a nontrivial solution \( \Phi \in \mathcal{H} \). Here and throughout the rest of this paper, we denote by \( \mathcal{H} := L^2(\partial D) \times L^2(\partial D)^N \). Moreover, in our subsequent study when investigating the
Minnaert resonance, we may weaken the condition (2.19) by finding a solution $\Phi \in \mathcal{H}$ with $\|\Phi\|_{\mathcal{H}} = 1$ such that for $k \ll 1$,

$$\|\tilde{A}(\omega, \delta)[\Phi](x)\|_{\mathcal{H}} \ll 1.$$  

(2.20)

If the condition (2.20) is fulfilled, we say that the weak (Minnaert) resonance occurs for the system (2.2). In contrast to the weak Minnaert resonance, when the condition (2.19) is fulfilled, we say that the strong (Minnaert) resonance occurs.

Finally, we give a remark on the definition of the Minnaert resonance introduced above. In fact, the definition of the strong (Minnaert) resonance is similar to the one introduced in [1] for the bubble-liquid resonance. For the weak resonance, let us assume that $\tilde{\Psi} = \tilde{A}(\omega, \delta)[\Phi]$. According to (2.20), one has that $\|\tilde{\Psi}\|_{\mathcal{H}} \ll 1$.

Set $\Psi = \tilde{\Psi}/\|\tilde{\Psi}\|_{\mathcal{H}}$ such that $\|\Psi\|_{\mathcal{H}} = 1$. If $F$ in (2.18) is properly chosen which has a component being $\Psi$, one can easily conclude from (2.17) that the scattering wave will blow up at the order $1/\|\tilde{\Psi}\|_{\mathcal{H}}$.

3. General requirements on the medium configuration and auxiliary results on the layer-potential operators

In this section, we first introduce some general requirements on the medium configuration that are critical for the occurrence of the Minnaert resonances in our subsequent constructions of the bubble-elastic structures in Sections 4 and 5. Then we derive some auxiliary results for the subsequent use.

3.1. General requirements on the medium configuration. We first introduce the following assumption,

$$\delta = \rho_b/\rho_e = o(1),$$  

(3.1)

which states that the contrast of the densities of the bubble and the elastic material is high. Moreover, we assume that the bulk modulus of the air $\kappa$ and the compression modulus $\lambda$ as well as the shear modulus $\mu$ of the elastic material satisfy the following relationship

$$\kappa/\lambda = \mathcal{O}(\delta) \quad \text{and} \quad \tilde{\mu}/\tilde{\lambda} = o(1).$$  

(3.2)

Under these assumptions, one further has that

$$\tau = c_b/\tilde{c}_p = \frac{\sqrt{\kappa/\rho_b}}{\sqrt{(\lambda + 2\tilde{\mu})/\rho_e}} = \mathcal{O}(1),$$  

(3.3)

where $c_b$ and $\tilde{c}_p$ are defined in (2.2) and (2.7), respectively. Indeed, the assumptions in (3.1) and (3.2) are reasonable and this is the case that air bubbles are embedded in the polydimethylsiloxane, a soft elastic material (cf. [11]).

As a matter of fact, the low-frequency is mainly caused by the fact that the size of the air bubble $D$ is much smaller than the wavelength of the elastic wave. Since the elastic wave can be decomposed into the compressional wave (p-wave) and the shear wave (s-wave) [14], in this paper, we are mainly concerned with the case that the wavelength of the p-wave is much larger than the size of the bubble $D$ and the wavelength of the s-wave generically does not satisfy this requirement. That means that the Minnaert resonance is mainly caused by the p-wave. Thus by the coordinate transformation, we may assume
that the size of the domain $D$ is of order 1 and $\omega = o(1)$. Since $c_b$ is fixed, one can further have that

$$\tilde{k} = o(1) \quad \text{and} \quad \tilde{k}_p = o(1),$$

where $\tilde{k}$ and $\tilde{k}_p$ are defined in (2.2) and (2.7), respectively.

Let $L$ be the typical length (average length) of the domain $D$. Then we introduce the following non-dimensional parameters:

$$\tilde{x}' = x/L, \quad k = \tilde{k}L, \quad u' = u/L, \quad \mu = \tilde{\mu}/(\tilde{\lambda} + 2\tilde{\mu}), \quad \lambda = \tilde{\lambda}/(\tilde{\lambda} + 2\tilde{\mu}), \quad u' = u/(\rho b c_b^2).$$

Thus from the assumptions made above, one has that

$$k = o(1), \quad \delta = \rho_b/\rho_e = o(1), \quad \tau = O(1), \quad \mu = o(1) \quad \text{and} \quad \lambda = O(1).$$

Substituting these parameters into equation (2.2) and dropping the primes, one can obtain the following coupled PDE system for our subsequent study,

\[
\begin{align*}
\mathcal{L}_{\lambda, \mu} u(x) + k^2 \tau^2 u(x) &= 0, & x &\in \mathbb{R}^N \setminus \bar{D}, \\
\Delta u(x) + k^2 u(x) &= 0, & x &\in D, \\
u(x) \cdot \nabla u(x) + k^2 \tau^2 u(x) \cdot \nu &= 0, & x &\in \partial D, \\
u(x) - u_i(x) &\text{ satisfies the radiation condition},
\end{align*}
\]

where $\tau$ is defined in (3.3). Here we would like to point out that in (3.6), the p-wavenumber satisfies

$$k_p = \frac{k \tau}{c_p} = \frac{k \tau}{\sqrt{\lambda + 2\mu}} = o(1).$$

Following our earlier discussion in (2.17)–(2.19), the solution to the system (3.6) can be given by

$$u = \begin{cases} S_D^k(\varphi_b)(x), & x \in D, \\ S_D^k(\varphi_e)(x) + u^i, & x \in \mathbb{R}^N \setminus \bar{D}, \end{cases}$$

for some surface densities $(\varphi_b, \varphi_e) \in \mathcal{H}$ that satisfy:

$$\mathcal{A}(k, \delta)[\Phi](x) = F(x), \quad x \in \partial D,$$

where

$$\mathcal{A}(k, \delta) = \begin{pmatrix} \frac{1}{k^2} \left( -\frac{1}{2} + K_{DD}^{k,t,s} \right) & -\nu \cdot S_{DD}^k \tau^2 \nu \cdot S_{DD}^k \tau^2 \\ \delta^2 \nu \cdot S_{DD}^k \tau^2 \nu \cdot S_{DD}^k \tau^2 & \frac{1}{2} + K_{DD}^{k,t,s} \end{pmatrix}, \quad \Phi = \begin{pmatrix} \varphi_b \\ \varphi_e \end{pmatrix} \quad \text{and} \quad F = \begin{pmatrix} \nu \cdot u_i \\ -\partial \nu u_i \end{pmatrix}.$$
3.2. Some auxiliary results. We first introduce the following three lemmas.

**Lemma 3.1.** If a vector field $w \in H^1(\mathbb{R}^3 \setminus \overline{D})^3$ satisfies the following three equations:
\[
\triangle w + k^2 w = 0, \quad \nabla \times w = 0 \quad \text{and} \quad \nabla \cdot w = 0,
\]
then $w = 0$.

**Proof.** Direct calculation shows that
\[
\nabla \times \nabla \times w = \nabla \nabla \cdot w - \triangle w = 0 + k^2 w = 0.
\]
Thus one can obtain $w = 0$ since $k^2 \neq 0$.

**Lemma 3.2.** If $\varphi \in \ker (S_{DD}^{w,s})$, then one has that
\[
S_{DD}^{w,p}[\varphi](x) = \frac{1}{\lambda + 2\mu} \int_{\partial D} G_{kr}(x-y) \varphi(y) dy, \quad x \in \mathbb{R}^3 \setminus D,
\]
where the operators $S_{DD}^{w,i}$, $i = p, s$, are defined in (2.16).

**Proof.** From the definition of the fundamental solution in (2.12), if $\varphi \in \ker (S_{DD}^{w,s})$, one has that
\[
\int_{\partial D} \frac{1}{\rho \omega^2} (k^2 I + \nabla \nabla) G_{kr}(x-y) \varphi(y) dy = 0, \quad x \in \mathbb{R}^3 \setminus \overline{D}.
\]
Replacing $k_s$ with $k_p$ in the last equation yields that for $x \in \mathbb{R}^3 \setminus \overline{D}$,
\[
\int_{\partial D} \frac{1}{\rho \omega^2} (\nabla \nabla) G_{kr}(x-y) \varphi(y) dy = \frac{1}{\lambda + 2\mu} \int_{\partial D} G_{kr}(x-y) \varphi(y) dy.
\]
The proof is readily completed by noting that the operator $S_{DD}^{k_p}$ is continuous from $\mathbb{R}^3 \setminus \overline{D}$ to $\mathbb{R}^3 \setminus D$.

**Remark 3.1.** We remark that $\ker (S_{DD}^{w,s}) \neq \emptyset$ and $\nu \in \ker (S_{DD}^{w,s})$. Indeed, we set
\[
w(x) = \int_{\partial D} \frac{1}{\rho \omega^2} (k^2 I + \nabla \nabla) G_{kr}(x-y) \nu(y) ds(y), \quad x \in \mathbb{R}^3 \setminus \overline{D}. \tag{3.11}
\]
It is directly verified that the function $w$ defined in (3.11) satisfies the following two equations in $\mathbb{R}^3 \setminus \overline{D}$,
\[
\triangle w + k^2 w = 0 \quad \text{and} \quad \nabla \cdot w = 0.
\]
With the help the identities
\[
\nabla \times \nabla = 0 \quad \text{and} \quad \nabla \times G_{kr}(x-y) = -\nabla y G_{kr}(x-y),
\]
one furthermore has that, for $x \in \mathbb{R}^3 \setminus \overline{D}$,
\[
\nabla \times w = \int_{\partial D} \frac{1}{\rho \omega^2} (k^2 I + \nabla \nabla) G_{kr}(x-y) \nu(y) ds(y)
= \frac{1}{\rho \omega^2} \int_{\partial D} (k^2 \nabla \times I + \nabla \times \nabla) G_{kr}(x-y) \nu(y) ds(y)
= -\frac{k^2}{\rho \omega^2} \int_{\partial D} \nabla y G_{kr}(x-y) \times \nu(y) ds(y)
= \frac{k^2}{\rho \omega^2} \int_{D} \nabla y \times \nabla y G_{kr}(x-y) dy = 0.
\]
Finally, Lemma 3.4 shows that \( \mathbf{w} \) defined in (3.11) vanishes in \( \mathbb{R}^3 \setminus \overline{D} \) and one can conclude that \( \mathbf{v} \in \text{ker} \ (S_{\partial D}^{w,s}) \).

**Lemma 3.3.** In three dimensions, for the operators \( S_{\partial D}^k : L^2(\partial D) \rightarrow H^1(\partial D) \) and \( K_{\partial D}^{k,s} : L^2(\partial D) \rightarrow L^2(\partial D) \) defined in (2.9) and (2.10), respectively, we have the following asymptotic expansions:

\[
S_{\partial D}^k = \sum_{j=0}^{+\infty} k^j S_{\partial D,j}, \tag{3.12}
\]

and

\[
K_{\partial D}^{k,s} = \sum_{j=0}^{+\infty} k^j K_{\partial D,j}^*, \tag{3.13}
\]

where

\[
S_{\partial D,j}[\varphi](x) = -\frac{i}{4\pi} \int_{\partial D} \frac{(|x - y|)^{j-1}}{j!} \varphi(y) ds(y),
\]

and

\[
K_{\partial D,j}^*[\varphi](x) = -\frac{j(j-1)}{4\pi j!} \int_{\partial D} |x - y|^{j-3} (x - y) \cdot \mathbf{v} \varphi(y) ds(y).
\]

Moreover, the norm \( \|S_{\partial D,j}\|_{L(L^2(\partial D),H^1(\partial D))} \) is uniformly bounded with respect to \( j \) and the series in (3.12) is convergent in \( L(L^2(\partial D),H^1(\partial D)) \). The norm \( \|K_{\partial D,j}^*\|_{L(L^2(\partial D))} \) is uniformly bounded with respect to \( j \) and the series in (3.13) is convergent in \( L(L^2(\partial D)) \).

Next, we give the asymptotic expansions for the operator \( S_{\partial D}^{w,p} : L^2(\partial D)^3 \rightarrow H^1(\partial D)^3 \) and \( K_{\partial D}^{w,p} : L^2(\partial D)^3 \rightarrow L^2(\partial D)^3 \), whose definition will be specified later. As discussed earlier, only the wavelength of the p-wave is required to be asymptotically larger than the size of the domain \( D \) and the wavelength of the s-wave is not required to satisfy such a requirement, thus the low-frequency resonance is mainly caused by the p-wave and the s-wave generically makes no contribution. Therefore, in the following analysis for the low-frequency resonance, we choose to mainly consider the density function \( \varphi \in \ker (S_{\partial D}^{w,s}) \). From Lemma 3.2 we can focus ourselves on the operator \( S_{\partial D}^{w,p} \) with the kernel \( \delta_{ij}G^{kp}/(\lambda + 2\mu) \) and the operator \( K_{\partial D}^{w,p} : L^2(\partial D)^3 \rightarrow L^2(\partial D)^3 \) defined in (2.14) with the kernel function \( \Gamma^{w} \) replaced by \( \delta_{ij}G^{kp}/(\lambda + 2\mu) \). By straightforward calculations, we have the following asymptotic expansion for the operators \( S_{\partial D}^{w,p} \) and \( K_{\partial D}^{w,p} \).

**Lemma 3.4.** In three dimensions, when the density function \( \varphi \in \ker (S_{\partial D}^{w,s}) \), the operators \( S_{\partial D}^{w,p} \) from \( L^2(\partial D)^3 \) to \( H^1(\partial D)^3 \) and \( K_{\partial D}^{w,p} \) from \( L^2(\partial D)^3 \) to \( L^2(\partial D)^3 \) enjoy the following asymptotic expansions:

\[
S_{\partial D}^{w,p} = \sum_{j=0}^{+\infty} k^j S_{\partial D,j}^p, \tag{3.14}
\]

and

\[
K_{\partial D}^{w,p} = \sum_{j=0}^{+\infty} k^j K_{\partial D,j}^{p,*}, \tag{3.15}
\]

where

\[
S_{\partial D,j}^p[\varphi](x) = -\frac{i}{4\pi} \int_{\partial D} \frac{(|x - y|)^{j-1}}{j!} \varphi(y) ds(y),
\]
\begin{equation}
\mathbf{K}_{\partial D,j}^{p,*}[\varphi](x) = \frac{\lambda}{\lambda + 2\mu} \mathbf{R}_{1,j}[\varphi](x) + \frac{\mu}{\lambda + 2\mu} \mathbf{R}_{2,j}[\varphi](x).
\end{equation}

In (3.16),
\begin{equation}
\mathbf{R}_{1,j}[\varphi](x) = -\frac{i(j-1)}{4\pi j^j} \int_{\partial D} |x - y|^{-j-3/4} (\nu_x \cdot \varphi)(y) ds(y).
\end{equation}

and
\begin{equation}
\mathbf{R}_{2,j}[\varphi](x) = -\frac{i(j-1)}{4\pi j^j} \left( \int_{\partial D} |x - y|^{-j-3/4} (\nu_x \cdot \varphi)(y) ds(y) + \int_{\partial D} |x - y|^{-j-3/4} (\nu_x \cdot \varphi(y)) ds(y) \right).
\end{equation}

Moreover, the norm \( \| \mathbf{S}_{\partial D,j}^p \|_{L^2(\partial D)^3, H^1(\partial D)^3)} \) is uniformly bounded with respect to \( j \) and the series in (3.14) is convergent in \( L^2(\partial D)^3, H^1(\partial D)^3) \). The norm \( \| \mathbf{K}_{\partial D,j}^{p,*} \|_{L^2(\partial D)^3)} \) is uniformly bounded with respect to \( j \) and the series in (3.15) is convergent in \( L^2(\partial D)^3) \).

Finally, we introduce the following function space
\begin{equation}
L^2_0(\partial D) = \{ \varphi \in L^2(\partial D) : \int_{\partial D} \varphi ds = 0 \},
\end{equation}
and the following two lemmas can be found in [6].

**Lemma 3.5.** Let \( \xi \) be a real number. The operator \( \xi - K_{\partial D,0}^* \) is invertible on \( L^2_0(\partial D) \) if \( |\xi| \geq 1/2 \), where \( L^2_0(\partial D) \) is defined in (3.17) and \( K_{\partial D,0}^* \) is given in (2.11). Furthermore, in the space \( L^2(\partial D) \), the kernel of the operators \( (-\frac{1}{2} + K_{\partial D,0}^*) \) is one dimensional and
\begin{equation}
\ker \left( -\frac{1}{2} + K_{\partial D,0}^* \right) = \text{span}\{S_{\partial D,0}^{-1}[1]\},
\end{equation}
where the operator \( S_{\partial D,0}^{-1} \) is the inverse of the operator \( S_{\partial D,0} \) defined in (2.9).

**Lemma 3.6.** Let \( f \in L^2(\partial D) \) satisfy \( (-\frac{1}{2} + K_{\partial D,0}) f = 0 \) with \( K_{\partial D,0} \) defined in (2.11). Then \( f \) is a constant.

4. Minnaert resonances in three dimensions

In this section, we show the Minnaert resonances for the system (3.6) in \( \mathbb{R}^3 \). First, we show that the weak resonance can always occur provided that the parameters are properly chosen. Then with proper choice of the geometry of the domain \( D \), we further show that enhanced or even strong resonances can occur.

**Theorem 4.1.** Consider the system (3.6) in three dimensions. If the parameters are chosen according to (3.1)–(3.2) (or, equivalently (3.5)), then weak Minnaert resonance can occur.

**Proof.** The proof is proceeded by construction. By the definition of the weak resonance in (3.10) for the system (3.6), we construct in what follows a density function \( \Phi \in \mathcal{H} \) with \( \| \Phi \|_{\mathcal{H}} = 1 \) such that the condition (3.10) is fulfilled.
Therefore, we choose
\[
\varphi_j = \left( \begin{array}{c} \varphi_j \\ \varphi_j \end{array} \right),
\]
for \( j \geq 0 \).

As discussed earlier, the resonance is mainly caused by the p-wave in our study. Therefore, we choose
\[
\varphi_j \in \ker \left( S_{\partial D,0}^{+} \right),
\]
for \( j \geq 0 \). Thus, from the definition of the operator \( A(k,0) \) in (3.8) and Lemmas 3.3 and 3.4 one has that
\[
A(k,0)[\Phi] = \frac{1}{k^2} \left( \begin{array}{c} \left( -\frac{i}{2} + K_{\partial D,0}^{*} \right) \varphi_0 \\ 0 \end{array} \right) + \frac{1}{k} \left( \begin{array}{c} \left( -\frac{i}{2} + K_{\partial D,0}^{*} \right) \varphi_1 \\ 0 \end{array} \right) +
\]
\[
\left( \begin{array}{c} K_{\partial D,0}^{*} \varphi_0 - \nu \cdot S_{\partial D,0}^{p} \varphi_0 + \left( -\frac{i}{2} + K_{\partial D,0}^{*} \right) \varphi_2 \\ \left( \frac{i}{2} + K_{\partial D,0}^{p,*} \right) \varphi_0 \end{array} \right) + O(k). \tag{4.1}
\]
Since \( k \ll 1 \), the first two terms in (4.1) should vanish. Thus one can conclude from Lemma 3.5 that
\[
\varphi_0, \varphi_1 \in \ker \left( -\frac{i}{2} + K_{\partial D,0}^{*} \right) = \text{span}\{S_{\partial D,0}^{-1}[1]\}. \tag{4.2}
\]
Next we deal with the third term in (4.1). From the definition of \( K_{\partial D,0}^{p,*} \) in (3.16), one has that
\[
K_{\partial D,0}^{p,*}[\varphi_0](x) = \frac{\lambda}{\lambda + 2\mu} R_{1,0}[\varphi_0] + \frac{\mu}{\lambda + 2\mu} R_{2,0}[\varphi_0], \tag{4.3}
\]
where
\[
R_{1,0}[\varphi_0] = \nu_{\lambda} \int_{\partial D} \frac{(x - y, \varphi_0)}{4\pi|\lambda - y|^3} ds(y), \tag{4.4}
\]
and
\[
R_{2,0}[\varphi_0] = \int_{\partial D} \frac{(x - y, \nu_{\lambda})}{4\pi|\lambda - y|^3} \varphi_0 + \frac{(x - y, \nu_{\lambda})}{4\pi|\lambda - y|^3} ds(y). \tag{4.5}
\]
We can rewrite the equation (4.3) as follows
\[
K_{\partial D,0}^{p,*}[\varphi_0](x) = R_{1,0}[\varphi_0] - \frac{2\mu}{\lambda + 2\mu} R_{1,0}[\varphi_0] + \frac{\mu}{\lambda + 2\mu} R_{2,0}[\varphi_0] = R_{1,0}[\varphi_0] + O(\mu), \tag{4.5}
\]
by noting that the operators \( R_{1,0} \) and \( R_{2,0} \) are bounded from \( L^2(\partial D)^3 \) to \( L^2(\partial D)^3 \). Thus the leading term of \( K_{\partial D,0}^{p,*}[\varphi_0] \) is \( R_{1,0}[\varphi_0] \). From (4.1), \( R_{1,0}[\varphi_0] \) contains only the normal component. Therefore the second component of the third term in (4.1) indicates that the function \( \varphi_0 \) should also contain only the normal component, namely
\[
\varphi_0 = \varphi_{\nu},
\]
for some $\varphi \in L^2(\partial D)$. Thus
\[
\frac{1}{2} \varphi_0 + R_{1,0}[\varphi_0] = \nu \left( \frac{1}{2} \varphi - K_{\partial D,0}[\varphi] \right)
\]
and $\varphi$ should be a constant thanks to Lemma 3.6. Hence one finally obtains that
\[
\varphi_0 = c_0 \nu,
\]
for some constant $c_0$, which will be further determined later.

We proceed to deal with the first component of the third term in (4.1) by solving the following equation
\[
\left( -\frac{I}{2} + K_{\partial D,0}^* \right) [\varphi_2] = c_0 \nu \cdot S_{\partial D,0}[\nu] - K_{\partial D,2}^*[\varphi_0]. \tag{4.6}
\]
Lemma 3.3 shows that the operator $\left( -\frac{I}{2} + K_{\partial D}^* \right)$ is invertible on $L_0^2(\partial D)$. Thus $c_0$ should be chosen as follows
\[
c_0 = \frac{\int_{\partial D} K_{\partial D,2}^*[\varphi_0](x)ds(x)}{\int_{\partial D} \nu \cdot \nu |(x)ds(x)}, \tag{4.7}
\]
such that the equation (4.6) is solvable. Thus
\[
\varphi_2 = \left( -\frac{I}{2} + K_{\partial D,0}^* \right)^{-1} \left[ c_0 \nu \cdot S_{\partial D,0}[\nu] - K_{\partial D,2}^*[\varphi_0] \right].
\]
Following the same process, one can construct
\[
\varphi_3 = \left( -\frac{I}{2} + K_{\partial D,0}^* \right)^{-1} \left[ c_1 \nu \cdot S_{\partial D,0}[\nu] - K_{\partial D,2}[\varphi_1] + (\tau/c_0) c_0 \nu \cdot S_{\partial D,1}[\nu] - K_{\partial D,3}[\varphi_0] \right],
\]
\[
c_1 = \frac{\int_{\partial D} K_{\partial D,2}^*[\varphi_1](x) + K_{\partial D,3}[\varphi_0](x) - (\tau/c_0) c_0 \nu \cdot S_{\partial D,1}[\nu](x)dx}{\int_{\partial D} \nu \cdot \nu |(x)dx},
\]
\[
\varphi_3 = \left( -\frac{I}{2} + K_{\partial D,0}^* \right)^{-1} \left[ c_1 \nu \cdot S_{\partial D,0}[\nu] - K_{\partial D,2}[\varphi_1] + (\tau/c_0) c_0 \nu \cdot S_{\partial D,1}[\nu] - K_{\partial D,3}[\varphi_0] \right],
\]
\[
c_2 = \frac{\int_{\partial D} K_{\partial D,2}^*[\varphi_2](x) + K_{\partial D,3}[\varphi_1](x) + K_{\partial D,4}[\varphi_0](x)dx}{\int_{\partial D} \nu \cdot \nu |(x)dx} - \frac{\int_{\partial D} (\tau/c_0) \nu \cdot \nu \cdot S_{\partial D,1}[\nu](x)dx}{\int_{\partial D} \nu \cdot \nu |(x)dx},
\]
\[
\varphi_4 = \left( -\frac{I}{2} + K_{\partial D,0}^* \right)^{-1} \left[ c_2 \nu \cdot S_{\partial D,0}[\nu] - K_{\partial D,2}[\varphi_2] + K_{\partial D,3}[\varphi_1] + (\tau/c_0)^2 \nu \cdot \nu \cdot S_{\partial D,2}[\nu](x) \right].
\]
Then one can have that
\[
\mathcal{A}(\omega, \delta)[\Phi] = \begin{pmatrix} 0 & 0 \\ 0 & \mathcal{O}(k^3) \end{pmatrix},
\]
\[
\mathcal{O}(k^3) + \mathcal{O}(\delta k) + \mathcal{O}(\mu k)
\]
with $\Phi$ defined in (4.8). Finally one can conclude that

$$\|A(\omega, \delta)[\Phi](x)\|_{H} = \mathcal{O}(\delta) + \mathcal{O}(\mu) + \mathcal{O}(k^3) \ll 1,$$

which clearly shows that the weak resonance occurs.

The proof is complete. □

From the proof of Theorem 4.1, one readily sees that only diminishing the parameter $k$ cannot strengthen the resonance. The parameter $k$ should be chosen in an appropriate way that is correlated to the parameters $\delta$ and $\mu$ in order to achieve enhanced resonance effects. In fact, we have

**Proposition 4.1.** Consider a same setup as that in Theorem 4.1. If the following equation is solvable

$$\delta \tau^2 \nu + \mu \left( \frac{1}{\lambda + 2\mu} \right) \left( R_{2,0} - 2R_{1,0} \right) [c_0 \nu] + k^2 \left( \tau/c_p \right)^2 R_{1,2} [c_0 \nu] = 0, \quad (4.10)$$

then one has that

$$\|A(\omega, \delta)[\Phi](x)\|_{H} = \mathcal{O}(\delta k) + \mathcal{O}(\mu k) + \mathcal{O}(k^3), \quad (4.11)$$

which indicates that the enhanced resonance can be achieved. If (4.11) is solvable, the parameter $k$ should fulfil

$$k = \sqrt{\mathcal{O}(\delta) + \mathcal{O}(\mu)}. \quad (4.12)$$

**Proof.** If we take the density function $\Phi$ as in (4.8), and the equation in (4.10) is solvable, then from (4.9), one has that

$$A(\omega)[\Phi] = \left( \begin{array}{c} \mathcal{O}(k^3) \\ \mathcal{O}(\delta k) + \mathcal{O}(\mu k) \end{array} \right). \quad (4.13)$$

Thus the estimate in (4.11) is proved. Moreover, by noting that the functions

$$\left( R_{2,0} - 2R_{1,0} \right) [c_0 \nu] \quad \text{and} \quad R_{1,2} [c_0 \nu]$$

are bounded in $L^2(\partial D)^3$ and

$$\tau = \mathcal{O}(1) \quad \text{and} \quad \lambda = \mathcal{O}(1),$$

one can show by direct computations that if the equation (4.10) is solvable then the parameter $k$ fulfills

$$k = \sqrt{\mathcal{O}(\delta) + \mathcal{O}(\mu)}. \quad (4.12)$$

**Remark 4.1.** If the equation (4.10) is solvable, since the functions $R_{1,0} [\nu]$ and $R_{1,2} [\nu]$ contain only the normal components, thus the function $R_{2,0} [\nu]$ should also contain only the normal component. Indeed, this is also physically justifiable. From the fourth equation in (3.6), since the pressure in the bubble has only the normal component, to strengthen the resonance it is natural to require that the leading term of the traction of the elastic wave outside the bubble $D$ should contain only the normal component. This property heavily depends on the geometry of the domain $D$.

**Remark 4.2.** Since $\delta \ll 1$ and $\mu \ll 1$, from (4.11) and (4.12) in Proposition 4.1, one readily sees that enhanced resonance effects can be achieved.
Remark 4.3. We apply Proposition 4.1 to the case when the bubble $D$ is a unit ball. In such a case that $D$ is a unit ball, one has that for $x \in \partial D$,

$$S_{\partial D,0}^{-1}[1](x) = -1, \quad \text{and} \quad S_{\partial D,0}[\nu](x) = -\frac{1}{3}\nu.$$ 

Thus from (4.2), one has that

$$\varphi_0 = \varphi_1 = -1.$$ 

We first calculate the parameter $c_0$ defined in (4.7). Direct calculation shows that

$$\int_{\partial D} K_{\partial D,2}^{-1}[-1](x)ds(x) = -\frac{4\pi}{3}.$$ 

Hence, one obtains that

$$c_0 = \frac{\int_{\partial D} K_{\partial D,2}^{-1}[\varphi_0](x)ds(x)}{\int_{\partial D} \nu \cdot S_{\partial D,0}^{\rho}[\nu](x)ds(x)} = -\frac{4\pi}{3} - \frac{4\pi}{3(\lambda + 2\mu)} = \lambda + 2\mu.$$ 

From the proof in Theorem 4.1, one has that

$$R_{1,0}[\nu] = -\nu/2.$$ 

Moreover, by straightforward but rather tedious calculations, one can obtain that

$$R_{2,0}[\nu] = \nu/3 \quad \text{and} \quad R_{1,2}[\nu] = -\nu/3.$$ 

Therefore the equation (4.10) in Proposition 4.1 can be simplified to be

$$\delta \tau^2 \nu + \frac{4}{3} \mu \nu - \frac{1}{3} k^2 \tau^2 \nu = 0,$$

which shows that $k$ should be chosen as

$$k = \sqrt{3\delta + 4\mu/\tau^2}. \quad (4.14)$$

Substituting the parameters in (3.4) into the last equation shows that the resonance frequency should be

$$\omega = \sqrt{\frac{3\kappa + 4\mu}{\rho_e}},$$

which recovers the physical result in [7]. Definitely, (4.10) may be solvable in more general scenarios, which then yield bubble-elastic structures that can produce enhanced resonances.

As also discussed earlier, the geometry of the bubble shall also play a critical role in the resonance in our study. We next show that if the domain $D$ is properly chosen, then resonance effects can also be significantly enhanced.

Proposition 4.2. Consider the same setup as that in Theorem 4.1. Furthermore, if the following equation is solvable,

$$\delta \nu \sum_{j=0}^{m} \tau^2 k^j \sum_{i=0}^{j} S_{\partial D,i}[\varphi_{j-i}] + \frac{k^2 \tau^2}{c_\rho} \sum_{j=0}^{m} \sum_{i=2}^{j} \frac{(k\tau)}{c_\rho} \sum_{i=2}^{j} R_{1,i}[c_{j-2-i}\nu] +$$

$$\frac{\mu}{\lambda + 2\mu} \sum_{j=0}^{m} \sum_{i=0}^{j} \frac{(k\tau)}{c_\rho} \sum_{i=0}^{j} (R_{2,i} - 2R_{1,i})[c_{j-i}\nu] = 0,$$ 

where $\varphi_j$ is defined in (4.17), then one has that

$$\|A(\omega, \delta)[\Phi](x)\|_H = O(\delta k^{m+1}) + O(\mu k^{m+1}) + O(k^{m+3}). \quad (4.15)$$
Proof. Following the proof of Theorem 4.1 one can construct

\[
\Phi = \sum_{j=0}^{\infty} k^j \begin{pmatrix} \varphi_j \\ \varphi_j \end{pmatrix}
\]  
(4.17)

where \(\varphi_0, \varphi_1\) are the same as those in (4.2) and

\[
\varphi_j = \left( -\frac{I}{2} + K^{*}_{\partial D} \right)^{-1} \left[ \sum_{m=0}^{j-2} (\tau/c_p)^m \nu \cdot S^0_{\partial D,m}[\varphi_{j-2-m}] - \sum_{m=2}^{j} K^{*}_{\partial D,m}[\varphi_{j-m}] \right]
\]  
for \(j \geq 2\),

\[
\varphi_j = c_j \nu, \quad \text{for} \quad j \geq 0,
\]

with

\[
c_j = \frac{\int_{\partial D} \sum_{m=2}^{j} K^{*}_{\partial D,m}[\varphi_{j+2-m}](x) - \sum_{m=1}^{j} (\tau/c_p)^m \nu \cdot S^0_{\partial D,m}[\varphi_{j-m}](x) ds(x)}{\int_{\partial D} \nu \cdot S^0_{\partial D,0}[\nu] ds(x)}.
\]

It is remarked here that when calculating \(\Phi\) in (4.17), one should first calculate \(c_j\) to obtain \(\varphi_j\) and then calculate \(\varphi_{j+2}\) for \(j = 0, 1, 2, \ldots\), since \(\varphi_0, \varphi_1 \in \text{span}\{S^{-1}_{\partial D,0}[1]\}\).

Hence one has that

\[
A(\omega, \delta)[\Phi]_1 = 0,
\]

\[
A(\omega, \delta)[\Phi]_2 = \delta \nu \sum_{j=0}^{\infty} \tau^2 k^j \sum_{i=0}^{j} S_{\partial D,i}[\varphi_{j-i}] + \frac{k^2 \tau^2}{c_p^2} \sum_{j=0}^{\infty} \left( \frac{k \tau}{c_p} \right)^{j+1} R_{1,i}[c_{j+2-i}\nu] + \frac{\mu}{\lambda + 2\mu} \sum_{j=0}^{\infty} \left( \frac{k \tau}{c_p} \right)^{j} \sum_{i=0}^{j}(R_{2,i} - 2R_{1,i})[c_{j-i}\nu],
\]

where \(A(\omega, \delta)[\Phi]_i\) denotes the \(i\)-th component of the vectorial function \(A(\omega, \delta)[\Phi]\) and the operators \(R_{i,j}\) with \(i = 1, 2\) and \(j \geq 0\), are defined in (3.16). Thus, if the equation (4.15) is solvable, one can conclude that

\[
\|A(\omega, \delta)[\Phi](x)\|_H = O(\delta k^{m+1}) + O(\mu k^{m+1}) + O(k^{m+3}).
\]

The proof is complete. \(\square\)

Remark 4.4. It is noted that if the equation (4.15) is solvable, then one should have

\[
k = \sqrt{O(\delta)} + O(\mu),
\]

and

\[
R_{2,i}[\nu] = \psi_i \nu, \quad \text{for} \quad 0 \leq i \leq m,
\]  
(4.18)

with \(\psi_i \in L^2(\partial D)\). The identities in (4.18) is reasonable as explained in Remark 4.1.

Remark 4.5. Proposition 4.1 is a special case of Proposition 4.2 with \(m = 0\). Indeed, even though the equation (4.15) could be solved for \(m > 0\), it is enough to solve the equation (4.15) with \(m = 0\), namely the equation (4.10) in Proposition 4.1 to obtain the resonant frequency. This is because that it gives the leading-order term of the resonant frequency.

Remark 4.6. If the equation (4.15) is solvable for \(m = \infty\), then the function \(\Phi\) defined in (4.17) belongs to the kernel of the operator \(A(\omega, \delta)\), namely the condition (3.9) is fulfilled. In this case, condition (4.18) signifies that \(\nu\) should be an eigenfunction of the operator \(K^{\omega*}_{\partial D}\). In fact, this is the case when the domain \(D\) is a ball. In [16], it is proved that \(\nu\) is an eigenfunction of the operator \(K^{\omega*}_{\partial D}\), namely

\[
K^{\omega*}_{\partial D}[\nu] = \chi_1 \nu, \quad x \in \partial D,
\]  
(4.19)
Moreover, \( \nu \) and \( \nu \) is also an eigenfunction of the operator \( S_{0D}^\nu \), namely

\[
S_{0D}^\nu(\nu)(x) = \frac{-iR^2k_R}{(\lambda + 2\mu)}h_1(k_R)j_1(k_R)\nu, \quad x \in \partial D.
\]

(4.20)

It is also proved in [23] that

\[
S_{0D}^\nu[1](x) = -iR^2h_0(k_R)j_0(k_R), \quad x \in \partial D,
\]

(4.21)

and

\[
K_{0D}^\nu[1](x) = \frac{1}{2} - ik^2R^2j_0^2(k_R)h_0(k_R), \quad x \in \partial D.
\]

(4.22)

Following the asymptotic expansions for the functions \( j_n(|x|) \) and \( h_n(|x|) \), \( n = 0, 1 \), with \( |x| \ll 1 \) (cf. [13]), one can obtain the expressions for \( S_{0D,i}[1] \), \( R_{1,i}[\nu] \) and \( R_{2,i}[\nu] \) for \( i \geq 0 \), respectively. Next we only present the first few terms,

\[
\delta \tau^2 + \frac{4}{3} - ik\left(\frac{3\tau^3\delta + 4\tau\mu}{3\sqrt{\lambda + 2\mu}}\right) - k^2\left(\frac{1}{3} - \frac{1}{3}\tau^2 + \frac{1}{6}\tau^2\delta\right) + k^3\cdot \frac{\tau^3\delta}{2\sqrt{\lambda + 2\mu}} + \cdots.
\]

One can readily see the equation \((4.24)\) is reduced to solving a polynomial equation with respect to \( k \) of an infinity order. By truncation and approximation, we solve the following equation,

\[
\delta \tau^2 + \frac{4}{3} - ik\left(\frac{3\tau^3\delta + 4\tau\mu}{3\sqrt{\lambda + 2\mu}}\right) - k^2\left(\frac{1}{3} - \frac{1}{3}\tau^2 + \frac{1}{6}\tau^2\delta\right) = 0.
\]

(4.23)

whose roots are given by

\[
k_{3d \pm} = \pm\sqrt{(3\tau^2\delta + 4\mu)(4(\lambda + \mu) - 3\tau^2\delta) - (3\tau^2\delta + 4\mu)}i.
\]

(4.24)

One can verify directly that the root \((4.24)\) is the positive part of the roots \((4.24)\) neglecting the infinitesimal part. In fact, the critical values obtained in \((4.24)\) exhibit excellent accuracy for the resonant frequencies; see Remarks \((5.1)\) and \((5.2)\) in what follows.

5. Minnaert resonances in two dimensions

In this section, we derive the Minnaert resonances for the system \((3.6)\) in two dimensions when the domain \( D \) is a unit disk.

In what follows, we let \( J_n(|x|) \) and \( H_n(|x|) \) respectively denote the Bessel function of order \( n \) and the Hankel function of the first kind of order \( n \). When the argument \( k \ll 1 \), the functions \( J_n \) and \( H_n \), \( n = 0, 1 \) enjoy the following asymptotic expansions (cf. [9]),

\[
J_0(k) = 1 - \frac{k^2}{4} + \frac{k^4}{64} + O(k^6), \quad J_1(k) = \frac{k}{2} - \frac{k^3}{16} + O(k^5),
\]

(5.1)

\[
H_0(k) = \frac{i(\gamma + 2\ln(k))}{\pi} + \frac{i(-2 + \gamma + 2\ln(k))k^2}{4\pi} + O((1 + \ln(k))k^3),
\]

(5.2)

and

\[
H_1(k) = -\frac{2i}{k\pi} + \frac{i(-1 + \gamma + 2\ln(k))k}{2\pi} + O((1 + \ln(k))k^3),
\]

(5.3)
where
\[ \gamma = 2E_c - i\pi - 2\ln(2), \]
with \( E_c \) denoting the Euler’s constant.

By the definition of the strong resonance in (3.9) for the system (3.6), we next construct a nontrivial solution \( \Phi \) such that
\[ A(k,\delta)[\Phi](x) = 0, \quad (5.4) \]
where \( A(k,\delta) \) is defined in (3.8). If the domain \( D \) is a unit disk, direction calculations show that for \( x \in \partial D \)
\[ S_{\partial D}^{k\tau}[\nu](x) = \zeta_1 \nu \quad \text{and} \quad K_{\partial D}^{k\tau,\ast}[\nu](x) = \zeta_2 \nu, \quad (5.5) \]
where
\[ \zeta_1 = \frac{-i\pi}{2(\lambda + 2\mu)} J_1(k_p) H_1(k_p), \]
and
\[ \zeta_2 = \frac{-i\pi J_1(k_p)}{2(\lambda + 2\mu)} \left( (\lambda + 2\mu)k_p H_1'(k_p) + \lambda H_1(k_p) \right) - \frac{1}{2}, \]
with \( k_p = k\tau/\sqrt{\lambda + 2\mu} \).

Moreover, one has that for \( x \in \partial D \) (cf. [17])
\[ S_{\partial D}[1](x) = \zeta_3 \quad \text{and} \quad K_{\partial D}^{k\tau,\ast}[1](x) = \zeta_4, \quad (5.6) \]
where
\[ \zeta_3 = \frac{-i\pi}{2} J_0(k_p) H_0(k) \quad \text{and} \quad \zeta_4 = \frac{1}{2} - \frac{i\pi}{2} k_p J_0(k_p) H_0(k). \]
Hence the nontrivial solution to the equation (5.4) should have the following form
\[ \Phi = \begin{pmatrix} b_1 \\ b_2 \end{pmatrix} \nu. \]
Substituting the last equation into (5.4) yields that
\[ Bb = 0, \quad (5.7) \]
where
\[ B = \begin{pmatrix} -\frac{1}{k^2} & -\zeta_1 \\ \delta\tau^2 \zeta_3 & \frac{1}{2} + \zeta_2 \end{pmatrix} \quad \text{and} \quad b = \begin{pmatrix} b_1 \\ b_2 \end{pmatrix}, \]
with \( \zeta_i, \ i = 1, 2, 3, 4 \) defined in (5.5) and (5.6). To ensure that the equation (5.7) possesses nontrivial solutions, the determinant of the matrix \( B \) should vanish, namely \( \det(B) = 0 \). Through straightforward but rather tedious calculations and with the help of the asymptotic expressions in (5.1), (5.2) and (5.3), one can obtain that
\[ \det(B) = \frac{1}{k^2} \left( -\frac{1}{2} + \zeta_4 \right) \left( \frac{1}{2} + \zeta_2 \right) + \delta\tau^2 \zeta_1 \zeta_3 \]
\[ = -(\gamma + 2\ln(k)) \left( \frac{\mu + \delta\tau^2}{4(\lambda + 2\mu)} + \frac{k^2\tau^2\lambda(\gamma + 2\ln(k/\sqrt{\lambda + 2\mu}))}{16(\lambda + 2\mu)^2} \right) + o(\mu(\gamma + \ln(k))) + o(\delta(\gamma + \ln(k))) + o(k^2(\gamma + \ln(k))), \]
where \( \gamma \) is defined in (5.2). Hence, we readily have
\[ i = 2 \quad i = 3 \quad i = 4 \]

| \( k_{b2} \) | 0.110087 − 0.040732i | 0.030796 − 0.007347i | 0.008681 − 0.001513i |
| \( k_{d2} \) | 0.109963 − 0.040294i | 0.030790 − 0.007341i | 0.008681 − 0.001513i |
| \( k_{b3} \) | 0.262065 − 0.034521i | 0.083584 − 0.003495i | 0.026454 − 0.000349i |
| \( k_{d3+} \) | 0.262296 − 0.034655i | 0.083592 − 0.003496i | 0.026455 − 0.000349i |

Table 1. The critical values of \( k_{b2}, k_{d2}, k_{b3} \) and \( k_{d3+} \) with positive real parts.

**Theorem 5.1.** Consider the system \((3.6)\) in two dimensions with \( D \) being a central disk. If the parameters are chosen according to \((3.5)\), then strong resonance can occur. Moreover, the leading-order terms of the resonant frequencies are given by the roots of the following equation

\[
(\gamma + 2 \ln(k)) \left( (\mu + \delta \tau^2) + \frac{k^2 \tau^2}{4(\lambda + 2\mu^2)} \right) = 0,
\]

where \( \tau \) and \( \gamma \) are given in \((3.3)\) and \((5.2)\), respectively.

**Remark 5.1.** The method used above in deriving the resonances in two dimensions can be applied to the three dimensions as well when the domain \( D \) is a central ball. From \((4.19)\) to \((4.22)\), one can calculate in a similar manner the determinant of the matrix \( B \) in three dimensions and determine the critical values \( k \)'s such that the following

\[ \det(B) = 0, \]

holds to ensure the occurrence of the strong resonance.

**Remark 5.2.** There exist critical values \( k \)'s such that \( \det(B) \) vanishes in both two and three dimensions; that is the strong resonance can occur. Since the expression of \( \det(B) \) is nonlinear with respect to \( k \), we can resort to computational algorithms to determine these critical values, namely resonant frequencies. Next, for illustrations, we conduct some numerical experiments to find out these critical values. We denote by \( k_{b2} \) and \( k_{b3} \) for the critical values by directly solving the equation \( \det(B) = 0 \) in two and three dimensions, respectively. As comparisons, we also calculate \( k_{d3+} \) defined in \((4.24)\) and solve the equation \((5.8)\). The root of the equation \((5.8)\) is denoted by \( k_{d2} \). The parameters in our numerical experiments are chosen as follows

\[ \lambda = 1, \quad \tau = 1, \quad \mu = \delta = 10^{-i}, \quad i = 2, 3, 4. \]

Moreover, the bubble \( D \) is a unit disk in \( \mathbb{R}^2 \) and a unit ball in \( \mathbb{R}^3 \). It is remarked that the case \( i = 3 \) almost indicates the experiment in \([11]\). The corresponding values, \( k_{b2}, k_{d2}, k_{b3} \) and \( k_{d3+} \) with positive real parts, are presented in Table 1. From Table 1, one can conclude that there indeed exist critical values \( k \) such that \( \det(B) = 0 \) in both two and three dimensions. Moreover, the roots of the equations \((4.23)\) and \((5.8)\) exhibit an excellent accuracy agreement with the resonant frequencies. Finally, we would like to point out the negative imaginary parts in the values computed in Table 1 are a physically reasonable requirement (cf. \([1]\)).
6. Concluding remarks

In this paper, we consider the Minnaert resonances for bubble-elastic structures. By delicately and subtly balancing the acoustic and elastic parameters as well as the geometry of the bubble, we show that Minnaert resonance can (approximately) occur for rather general constructions. Our study opens up a new field of mathematical investigation on bubbly elastic mediums with many potential developments. In the present paper, we only considered the case that a single bubble is embedded in a soft elastic material. It would be interesting to consider the case with multiple bubbles as well as the corresponding application to the effective realisation of elastic metamaterials. Moreover, we only investigated the case that the resonance is mainly caused by the p-wave, it would be interesting to investigate more general bubbly elastic structures with more general resonances. We shall consider these and other related topics in our forthcoming work.
