Abstract

The inverse problem method is tested for a class of monomer-dimer statistical mechanics models that contain also an attractive potential and display a mean-field critical point at a boundary of a coexistence line. The inversion is obtained by analytically identifying the parameters in terms of the correlation functions and via the maximum-likelihood method. The precision is tested in the whole phase space and, when close to the coexistence line, the algorithm is used together with a clustering method to take care of the underlying possible ambiguity of the inversion.

Keywords: inverse problem, mean-field model, metastable states, clustering algorithms

(Some figures may appear in colour only in the online journal)

1. Introduction

In the last decade a growing corpus of scientific research has been built that focus on the attempt to infer parameters by reconstructing them from statistical observations of systems. The problem itself is known as statistical inference and traces back to the times when the mathematical-physics description of nature became fully operative thanks to the advances of mechanics and calculus, i.e. with the French mathematicians Laplace and Lagrange. In recent times this field and its most ambitious problems have deeply connected with statistical physics\textsuperscript{[1–3]} at least in those cases in which the structure of the problem include the assumption of an underlying model to describe the investigated phenomena. The aforementioned
connection is surely related to the ability that statistical physics has acquired to describe phase transitions. In this paper we study the inverse problem for a model of interacting monomer-dimers in the mean-field, i.e. in the complete, graph. The denomination comes from the fact that the standard calculation in statistical mechanics, i.e. the derivation of the free energy and correlation from the assignment of the parameters is called the direct problem. Monomer-dimer models appeared in equilibrium statistical mechanics to describe the process of absorption of monoatomic or diatomic molecules in condensed matter lattices [4]. From the physical point of view monomers and dimers cannot occupy the same site of the lattice due to the hard-core interaction i.e. the strong contact repulsion generated by the Pauli exclusion principle. Beside such interaction though, as first noticed by Peierls [5], the attractive component of the Van der Waals potentials might influence the phase structure of the model and the thermodynamic behaviour of the material. In the mean-field setting analysed here the monomer-dimer model displays the phenomenon of phase coexistence among the two types of particles [6–8]. This makes the inverse problem particularly challenging since in the presence of phase coexistence the non uniqueness of its solution requires a special attention in identifying the right set of configurations. Under mean-field theory, the monomer-dimer model can be solved for the monomer densities and the correlations between monomers and dimers: the mean-field solution is inverted to yield the parameters of the model (external field and imitation coefficient) as a function of the empirical observables. The inverse problem has also been known for a long time as Boltzmann machine learning [9]. Its renewed interest is linked to the large number of applications in many different scientific fields like biology [10–13], computer science for the matching problem [14–16] and also social sciences [17, 18].

In this paper we follow an approach to the inverse problem similar to the one introduced for the multi-species mean-field spin model in the work [19]. The paper is organised in the following chapters and results. In the second section we recall briefly the monomer-dimer model and we review the basic properties of its solution [6, 8]. In the third section we solve the inverse problem: using the monomer density and the susceptibility of the model, we compute the values of the two parameters, here called coupling constants, $J$ and $h$. The first measure the preference for a vertex to be occupied by a monomer (respectively dimer), by imitating his neighbours. Firstly we identify the analytical inverse formulas providing an explicit expression of the free parameters in terms of the mentioned macroscopic thermodynamic variables. Then we use the maximum likelihood estimation procedure in order to provide an evaluation of the macroscopic variables starting from real data. The fourth section presents and discusses a set of numerical tests for finite number of particles and finite number of samples. The dependence of the monomer density and the susceptibility is studied with respect to the system size. We find that both of them have a monotonic behavior which depends on the parameters value and reach their limiting values with a correction that vanishes as at the inverse volume. We then investigate how the experimental monomer density and susceptibility at fixed volume depend on the number of samples. The effectiveness of the inversion is tested for different values of the imitation coefficients and external fields. After observing that the error of the inversion does not vanish when the parameters are close to the coexistence phase we investigate the effectiveness of clustering algorithms to overcome the difficulty. We find in all cases that the inverse method reconstructs, with a modest amount of samples, the values of the parameters with a precision of a few percentages. The paper has two technical appendices: the first on the rigorous derivation of the exact inverse formulas, the second that supports the first and studies the non homogeneous Laplace method convergence to the second order.
2. Definition of the model

Let \( G = (V, E) \) be a finite simple graph with vertex set \( V \) and edge set \( E = \{ uv \equiv \{ u, v \} \mid u \neq v \in V \} \).

**Definition 2.1.** A dimer configuration \( D \) on the graph \( G \) is a set of dimers (pairwise non-incident edges):

\[
D \subseteq E \quad \text{and} \quad (uv \in D \Rightarrow uw \notin D \ \forall w \neq v).
\]

The associated set of monomers (dimer-free vertices), is denoted by

\[
\mathcal{M}(D) := \mathcal{M}_G(D) := \{ u \in V \mid uv \notin D, \forall v \in V \}.
\]

Given a dimer configuration \( D \in \mathcal{D}_G \), we set for all \( v \in V \) and \( e \in E \)

\[
\alpha_v(D) := \begin{cases} 1, & \text{if } v \in \mathcal{M}(D) \\ 0, & \text{otherwise} \end{cases}
\]

and

\[
\alpha_e(D) := \begin{cases} 1, & \text{if } e \in D \\ 0, & \text{otherwise}. \end{cases}
\]

**Definition 2.2.** Let \( \mathcal{D}_G \) be the set of all possible dimer configurations on the graph \( G \). The imitative monomer-dimer model on \( G \) is obtained by assigning an external field \( h \in \mathbb{R} \) and an imitation coefficient \( J \geq 0 \) which gives an attractive interaction among particles occupying neighbouring sites. The Hamiltonian of the model is defined by the function \( H_{G}^{\text{imd}} : \mathcal{D}_G \rightarrow \mathbb{R} \) such that

\[
H_{G}^{\text{imd}} := -\sum_{v \in V} h \alpha_v - \sum_{uv \in E} J(\alpha_u \alpha_v + (1 - \alpha_u)(1 - \alpha_v)).
\] (1)

The choice of the Hamiltonian naturally induces a Gibbs probability measure on the space of configuration \( \mathcal{D}_G \):

\[
\mu_{G}^{\text{imd}}(D) := \frac{\exp(-H_{G}^{\text{imd}}(D))}{Z_{G}^{\text{imd}}} \quad \forall D \in \mathcal{D}_G,
\] (2)

where the partition function

\[
Z_{G}^{\text{imd}} = \sum_{D \in \mathcal{D}_G} \exp(-H_{G}^{\text{imd}}(D))
\]

is the normalizing factor. The expectation value with respect to the Gibbs probability measure (2) will be denoted by \( \langle \cdot \rangle \) i.e. for every random variable \( f \) of the monomer-dimer configuration \( D \),

\[
\langle f \rangle = \frac{\sum_{D \in \mathcal{D}_G} f(D) \exp(-H_{G}^{\text{imd}}(D))}{Z_{G}^{\text{imd}}}.
\] (3)

The natural logarithm of the partition function is called pressure function and it is related to the free energy of the model.

The normalized expected fraction of monomers on the graph is called *monomer density*. It can also be obtained computing the derivative of the pressure per particle with respect to \( h \):
$$m_G^{\text{imd}} := \sum_{D \in D_G} \frac{|M(D)|}{|V|} \mu_G^{\text{imd}}(D) = \frac{\partial}{\partial h} \log Z_G^{\text{imd}}.$$  

It is easy to check that

$$2|D| + |M(D)| = |V|. \quad (4)$$

In this paper we study the imitative monomer-dimer model on the complete graph, that is

$$G = K_N = (V_N, E_N)$$

with $V_N = \{1, \ldots, N\}$ and $E_N = \{(u, v) \mid u, v \in V_N, u < v\}$.

In order to keep the pressure function of order $N$, it is necessary to normalize the imitation coefficient by $\frac{1}{N}$ because the number of edges grows like $N^2$ and to subtract the term $\log N \sum_{e \in E_N} \alpha_e$ to the external field. Thus we will consider the Hamiltonian $H_N^{\text{imd}} : D_N \to \mathbb{R}$,

$$H_N^{\text{imd}} := -\sum_{v \in V_N} h \alpha_v + \log N \sum_{e \in E_N} \alpha_e - \sum_{e \in E_N} \frac{J}{N} (\alpha_e (1 - \alpha_e)) \quad (5)$$

All the thermodynamic quantities will therefore be functions of $N$ and we are interested in studying the large volume limits.

Before studying the inverse problem, we briefly recall the main properties of the model (see [6, 8]).

Taking $m \in [0, 1]$, the following variational principle holds

$$p(m) = \sup_m \tilde{p}(m),$$

where $p^{\text{imd}}$ is the pressure of the model at the thermodynamic limit and

$$\tilde{p}(m, J, h) := -Jm^2 + \frac{1}{2} J + p^{\text{imd}}((2m - 1)J + h) \quad (6)$$

with $p^{\text{imd}}(\xi) := -\frac{1}{4} g(\xi) - \frac{1}{2} \log(1 - g(\xi)) = -\frac{1}{4} g(\xi) - \log(g(\xi)) + \xi \quad \forall \xi \in \mathbb{R}$ and $g(\xi) := \frac{1}{2} (\sqrt{\xi^2 + 4e^2} - e^2) \quad \forall \xi \in \mathbb{R}$. The solution of the model reduces to identifying the value $m^*$ that maximizes the function $\tilde{p}$ and it is found among the solutions of the consistency equation $m = g((2m - 1)J + h)$ that include, beside the equilibrium value, also the unstable and metastable points. It is possible to prove that $m^*$ (which represents the monomer density) is a smooth function for all the values of $J$ and $h$ with the exception of the coexistence curve $\Gamma(J, h)$. Such curve is differentiable in the half-plane $(J, h)$ which stems from the critical point $(J_c, h_c) = (\frac{1}{12}, \frac{1}{4} \ln(2\sqrt{2} - 2) - \frac{1}{2})$. As in the case of the mean-field ferromagnet the variational formula for the pressure (6) predicts regions of metastability i.e. values of the parameters $(J, h)$ for which two local maxima are present. As proved in [6–8], the region of metastability can be located between the curves $\psi_1(J, h)$ and $\psi_2(J, h)$ which for $i = 1, 2$ and $J \geq J_c$ are given by

$$\psi_i(J) := J + \frac{1}{2} \log a_i(J) - 2Jg \left( \frac{1}{2} \log a_i(J) \right),$$

where

$$\phi_i(J, h) := \frac{1}{2} - \frac{h}{2J} + \frac{1}{4J} \log a_i(J)$$

and

$$\psi_i(J, h) := \psi_i(J) + \phi_i(J, h).$$
\[ a_i(J) := -\left( \frac{1}{2J^2} + \frac{8}{2J} - 4 \right) + (-1)^i \left( 2 - \frac{1}{J} \right) \sqrt{\frac{1}{2J^2} - \frac{12}{2J} + 4}. \]

3. The inverse problem

The evaluation of the parameters of the model starting from real data is usually called inverse problem and amounts of two steps. The analytical part of the inverse problem is the computation of the values \( J \) and \( h \) starting from those of the first and second moment of the monomer (or dimer) density. The statistical part instead is the estimation of the values of the moments starting from the real data and using the maximum likelihood principle \([20]\) or the equivalent formulations in statistical mechanics terms \([21]\). For what it concerns the analytical part, using the results of Appendix A and B, it can be proved that in the thermodynamic limit the imitation coefficient and the external field can be respectively computed as

\[ J = -\frac{1}{2\chi} + \frac{2 - m^*}{4m^*(1 - m^*)}, \]  

(7)

and

\[ h = g^{-1}(m^*) - J(2m^* - 1) = \frac{1}{2} \log \left( \frac{m^{*2}}{1 - m^*} \right) - J(2m^* - 1). \]  

(8)

We denote by \( m_N \) and \( \chi_N \) the finite size monomer density average and susceptibility \( N(m_N^2) - \langle m_N \rangle^2 \), while their limiting values are denoted without the subscript \( N \).

For the statistical part we use the maximum likelihood estimation procedure. Given a sample of \( M \) independent dimer configurations \( D^{(1)}, \ldots, D^{(M)} \) all distributed according to the measure of Gibbs (2), the maximum likelihood function is defined by

\[ L(J, h) = \mu_N^{\text{M}}(D^{(1)}, \ldots, D^{(M)}) = \prod_{i=1}^{M} \frac{\exp(-H_N^{\text{M}}(D^{(i)}))}{\sum_{D \in D_N} \exp(-H_N^{\text{M}}(D))}. \]

The function \( L(J, h) \) reaches its maximum when the first and the second momentum of the monomer density are calculated from the data according to the following equations:

\[
\begin{aligned}
&\left\{ \begin{array}{l}
m_N = \frac{1}{M} \sum_{i=1}^{M} m_N(D^{(i)}), \\
m_N^2 = \frac{1}{M} \sum_{i=1}^{M} m_N^2(D^{(i)}).
\end{array} \right.
\end{aligned}
\]  

(9)

The inverse problem is therefore solved by the composition of (9) with (7) and (8). In particular, denoting by \( m_{\text{exp}} \) and \( \chi_{\text{exp}} \) respectively the average monomer density and the susceptibility computed from the sample

\[ m_{\text{exp}} = \frac{1}{M} \sum_{i=1}^{M} m_N(D^{(i)}) \quad \text{and} \quad \chi_{\text{exp}} = N \left( \frac{1}{M} \sum_{i=1}^{M} m_N^2(D^{(i)}) - m_{\text{exp}}^2 \right), \]  

(10)

the estimators of the model’s free parameters are

\[ J_{\text{exp}} = -\frac{1}{2\chi_{\text{exp}}} + \frac{2 - m_{\text{exp}}}{4m_{\text{exp}}(1 - m_{\text{exp})}}, \]  

(11)

and
\[ h_{\exp} = \frac{1}{2} \log \left( \frac{m_{\exp}^2}{1 - m_{\exp}} \right) - J_{\exp}(2m_{\exp} - 1). \] (12)

4. The inversion at finite volume and finite sample size

The aim of this chapter is to study the robustness of the inversion procedure, i.e. the computation of the parameters from real data. The idea is to infer the value of \( J \) and \( h \) from the configurations generated according to the distribution of the model. In order to compute efficiently the values of the statistical estimators \( m_{\exp} \) and \( \chi_{\exp} \) and in order to obtain a good approximation of the analytical inverse formulas in terms of finite size thermodynamic variables, we have to choose a large number of configurations of the sample and a large number of vertices of the graph, which are respectively identified by \( M \) and \( N \). Since in real data we have a finite number of vertices and a finite number of configurations, the robustness will be studied with respect to both these two quantities.

The data that we are going to use are extracted from a virtually exact simulation of the equilibrium distribution. In fact, the mean-field nature of the model allows to rewrite the Hamiltonian (1) as a function of the dimer, or monomer, density (see (4)):

\[ H^{\text{imd}}_N(d_N) = -N \left( J \left( 16d_N^2 - 4d_N + \frac{N - 1}{2N} \right) + h \left( 1 - 4d_N \right) - 2d_N \log N \right), \] (13)

where \( d_N = d_N(D) = \frac{|D|}{2N} \), or equivalently

\[ H^{\text{imd}}_N(m_N) = -N \left( J \left( m_N^2 - m_N + \frac{N - 1}{2N} \right) + hm_N + \frac{1}{2} \log N(m_N - 1) \right). \] (14)

In particular we use the following definition of the partition function:

\[ Z^{\text{imd}}_N = \sum_{|D|=0}^{[N/2]} c_N(D) e^{-H^{\text{imd}}_N(d_N(D))}, \] (15)

where the term \( c_N(D) = \frac{N!}{|D|!(N-2|D|)!} 2^{-|D|} \) is the number of the possible configurations with \(|D|\) dimers on the complete graph with \( N \) vertices. Using the previous representation of the partition function we extract large samples of dimer densities values according to the equilibrium distribution. Those will be used for the statistical estimation of the first two moments (9). We are going to illustrate the results with some examples. Figure 1 shows the finite size average monomer density \( m_N \) and finite size susceptibility \( \chi_N \) for the monomer-dimer model at different \( N \)'s for different couples of parameters \((J,h)\). The figure highlights the monotonic behavior of \( m_N \) and \( \chi_N \) as function of \( N \). We point out that the different monotonic behaviors of the finite size monomer density and susceptibility provide a useful information about the phase space region at which the system is found before applying the full inversion procedure. Figure 2 shows the power-law fits of the behavior of the finite size corrections both for monomer density and susceptibility. In order to test numerically our procedure, we consider 20 \( M \) — samples for each couple \((J,h)\) and we solve the inverse problem for each one of them independently; then we average the inferred values over the 20 \( M \) — samples. We denote by \( \overline{m}_{\exp}, \overline{\chi}_{\exp}, \overline{J}_{\exp} \) and \( \overline{h}_{\exp} \) such averaged quantities. The two panels of figure 3 represent the statistical dependence of the estimators \( m_{\exp} \) and \( \chi_{\exp} \) on the number \( M \) of the configurations.
Figure 1. Finite size average monomer density $m_N$ (upper panels) and susceptibility $\chi_N$ (lower panels) as a function of $N$ for the monomer-dimer model at different values of $J$ and $h$. The red continuous lines represent the values in the thermodynamic limit.

Figure 2. $J = 0.5$, $h = 0.1$. Upper panel: $|m_N - m|$ as a function of $N$ together with the best fit $aN^b$ for the data in the left upper panel of figure 1. We obtain $a = 0.306$, $b \in (0.1703, 0.4418)$ and $b = -0.8549$, $b \in (-0.9459, -0.7639)$ with a goodness of fit $R^2 = 0.9815$. Lower panel: $|\chi_N - \chi|$ as a function of $N$ together with the best fit $cN^d$ for the data in the left lower panel of figure 1. We obtain $c = 1.277$, $d \in (0.9883, 1.566)$ and $d = -0.9765$, $d \in (-1.024, -0.929)$ with a goodness of fit $R^2 = 0.9971$. 
To check out that dependence on the sample, we computed the values of the experimental estimators over a set of 20 independent instances of such samples. The errors are standard deviations on 20 different $M$ samples of the same simulation: we find numerical evidence that $M \geq 5000$ stabilizes the estimations.

To test numerically the inversion procedure, we take a sample of $M = 5000$ dimer configurations $\{D^{(i)}\}, i = 1, \ldots, M$ over a complete graph with $N = 2000$ vertices. We consider $J \in [0.1, 1.5]$ and we fix $h = 0.1$; the obtained values for this case are shown in the left panel of figure 4, where $\tilde{J}_{\text{exp}}$ and $\tilde{h}_{\text{exp}}$ are plotted as functions of $J$. Note that the inferred values of the parameters are in optimal agreement with the exact values. Observe that for large values of the sample. To check out that dependence on the sample $D^{(1)}, \ldots, D^{(M)}$, we computed the values of the experimental estimators over a set of 20 independent instances of such samples. The errors are standard deviations on 20 different $M$ samples of the same simulation: we find numerical evidence that $M \geq 5000$ stabilizes the estimations.
of $J$, the reconstruction gets worse since the interaction between particles grows, as shown by the increasing error bars that represent the standard deviations on 20 different $M$—samples of the same simulation. In figure 5 we represent the absolute errors as a function of the imitation coefficient in reconstructing $J$ and $h$ for the cases of figure 4.

Figure 6 shows the relative errors in reconstructing the parameters for increasing sizes of the graph. The results show that, for large values of $N$ and $M$, the inference of parameters fails to produce good result when the couple $(J,h)$ is close to the coexistence line. The relative errors indeed reach values up to 200% (see panel $(h)$). This fact is a strong limitation of the method when dealing with real data because, in such case, we do not have a prior control on where a possible coexistence line is, nor if it is present at all. We therefore need a different procedure to solve the inverse problem that we investigate in the following section.

5. The inversion at finite volume and finite sample size with clustered phase space

We are now going to work over the monomer-dimer inverse problem when the phase space doesn’t present only one equilibrium state, i.e. when the system undergoes a phase transition. We explain how to modify the mean-field approach we have seen above. If the model is defined for the parameters $J$ and $h$ such that the couple $(J,h) \in \Gamma$, the Gibbs probability density of the model presents two local maxima and we cannot study the inversion problem in a global way as we have done in the second section but we have to understand what happens in a local neighborhood of each maximum. Given $M$ independent dimer configurations $D^{(1)}, \ldots, D^{(M)}$ all distributed according to the Gibbs probability measure for this model, we can understand their behavior around $m_1$ and $m_2$ separating them in two sets, before applying formulas (11) and (12), i.e. we divide the configurations of the sample in clusters using the so called clustering algorithms which classify elements into classes with respect to their similarity (see [22–25] and also [26] for a different approach). The clustering algorithms we use are based on the distance between the monomer density of the configurations: we put them in the same group if they are close enough and far from the other
Figure 6. Left panels: relative errors in reconstructing the imitation coefficient $J$. Right panels: relative errors in reconstructing the external field $h$. The points of the phase space are coloured with respect to the errors which assume the highest values along the coexistence line. The gray bar on the right gives a range for the computed errors: the scale goes from white for the lowest to black for the highest. The blue curves $\psi_1$ and $\psi_2$ define the region of metastability (see [6–8]), the red curve is the coexistence line while $(J_c, h_c)$ is the critical point; the blue and red colors do not identify any error. The number of configurations of the sample is set to be $M = 500$. (a) $N = 100$. (b) $N = 100$. (c) $N = 500$. (d) $N = 500$. (e) $N = 1000$. (f) $N = 1000$. (g) $N = 3000$. (h) $N = 3000$.

J. Phys. A: Math. Theor. 50 (2017) 205002
clusters (the concept of distance between clusters will be discussed later). For an assigned value of \( d_c \) (a given topology) a unique histogram can be constructed in which every configuration has an assigned number of neighboring ones. The density clustering algorithm [22] is based on the idea that the cluster centers are identified as local peaks of the above histogram. For a suitable choice of the topology (\( d_c \)) two peaks are away from each other and can be resolved by the algorithm. More precisely for each configuration we compute its local density \( \rho_i \) and its distance \( \delta_i \) from the local maxima. These quantities depend on the euclidean distance \( d_{ij} = |m^{(i)} - m^{(j)}| \), where \( m^{(i)} \), for \( i = 1, \ldots, M \) is the monomer density of the configuration \( D^{(i)} \).

The local density \( \rho_i \) of \( D^{(i)} \) is defined by

\[
\rho_i = \sum_{j=1}^{M} \varphi(d_{ij} - d_c),
\]

where \( d_c \) is an arbitrary cutoff distance (we will discuss later the choice of \( d_c \)) and

\[
\varphi(x) = \begin{cases} 
1 & \text{if } x < 0 \\
0 & \text{otherwise.}
\end{cases}
\]

In other words, the local density \( \rho_i \) corresponds to the number of configurations that are closer than \( d_c \) to the configuration \( D^{(i)} \). The distances \( \delta_i \) are the minimum distance between the configuration \( D^{(i)} \) and any other configuration with higher local density:

\[
\delta_i = \min_{j: \rho_j > \rho_i} d_{ij},
\]

while for the configuration with the highest local density we take \( \delta_i = \max_j d_{ij} \).

Observe that the quantity \( \delta_i \) for the configurations that are local or global maxima in the density is much larger than the typical nearest neighbor distance. Thus cluster centers are chosen as configurations for which the \( \delta_i \) is anomalously large (this situation will be illustrated in example 5.1 in the following).

After the cluster centers have been found, each remaining configuration is assigned to its closest neighbor of local maxima.

**Remark 5.1.** The choice of the cutoff distance \( d_c \) is crucial for the results of the algorithm: if we take a too large or a too small value for \( d_c \) it is possible that the algorithm is not able to find correctly the cluster centers. From the results of our simulations it emerges that, if we want to solve the inverse problem over a complete graph with \( N = 3000 \) vertices working with a sample made of \( M = 10000 \) dimer configurations, we have the best reconstruction of the free parameters when \( d_c \) is setted to be equal to 0.01. Obviously the choice depends on the range where the clusters centers have to be found and on the number of configurations of which the sample is made. More in general we have seen that for large values of \( M \), the minimum absolute error in reconstructing parameters occurs when the cutoff distance is equal to \( \frac{C}{\pi} \).

**Remark 5.2.** We tested our inversion formulas using two other clustering algorithms, obtaining analogous results, which put a number of data points into \( K \) clusters starting from \( K \) random values for the centers \( x^{(1)}, \ldots, x^{(K)} \): the \( K \)-means clustering algorithm and the soft \( K \)-means clustering algorithm [23]. However the results we are going to talk about have been obtained using the density clustering algorithm: by using this algorithm we do not have to specify the number of clusters since it finds them by itself.
Remark 5.3. From the results of our simulations, according to the example 5.1 in the following, it emerges that, if the couple of parameters which defines the model is not close enough to the coexistence line, we have a better reconstruction of the parameters applying equations (11) and (12) to the configurations which belong to the largest cluster.

On the other hand, when the couple \((J, h)\) is near to the coexistence line \(\Gamma(J, h)\), we solve the problem applying equations (11) and (12) to each cluster and averaging the inferred values as follows. We define the respective observables of the two classes as

\[
m_{\exp}^{(k)} = \frac{1}{M_k} \sum_{i \in C_k} m_i
\]

and

\[
\chi_{\exp}^{(k)} = N \left( \frac{1}{M_k} \sum_{i \in C_k} m_i^2 - (m_{\exp}^{(k)})^2 \right),
\]

where \(k \in \{1, 2\}\), \(C_k\) is the set of indices of the configurations belonging to the \(k\)th cluster and \(M_k = |C_k|\) is its cardinality.

We now apply (11) separately to each group in order to obtain two different estimators \(J_{\exp}^{(1)}\) and \(J_{\exp}^{(2)}\); finally we take the weighted average of all the different estimates

\[
J_{\exp} = \frac{1}{M_1 + M_2} (M_1 J_{\exp}^{(1)} + M_2 J_{\exp}^{(2)})
\]

in order to obtain the estimate for the imitation coefficient.

To estimate the parameter \(h\), we first compute the values \(h_{\exp}^{(1)}\) and \(h_{\exp}^{(2)}\) within each cluster using equation (12) and the corresponding \(J_{\exp}^{(k)}\); the final estimate for \(h\) is given by the weighted average over the clusters

\[
h_{\exp} = \frac{1}{M_1 + M_2} (M_1 h_{\exp}^{(1)} + M_2 h_{\exp}^{(2)}).
\]

We now focus on some cases of clustered phase space and we solve the inverse problem applying the density clustering algorithm.

In order to test numerically the inversion procedure for the monomer-dimer model, we consider a sample of \(M = 10\,000\) dimer configurations \(D^{(1)}, \ldots, D^{(M)}\) over a complete graph with \(N = 3000\) vertices. We denote by the bar averaged quantities and the errors are standard deviations over 20 – \(M\) samples.

Example 5.1. Consider a monomer-dimer model defined by the couple

\((J, h) = (2.001, -0.4145)\);

the Gibbs probability distribution of the monomer densities for this choice of parameters is represented in figure 7. Given \(M = 10\,000\) independent dimer configurations \(D^{(1)}, \ldots, D^{(M)}\) all distributed according to the Gibbs probability measure for this model, we use the density clustering algorithm in order to divide them in two sets to reconstruct the parameters.

As we can see by figures 8 and 9, configurations are divided in two clusters \(C_1\) and \(C_2\) respectively centered in \(\bar{m}_1 = 0.1507 \pm 5.7 \cdot 10^{-17}\) and \(\bar{m}_2 = 0.9402 \pm 9.9 \cdot 10^{-4}\); moreover
the cluster centered in $m_1$ contains more configurations than that centered in $m_2$. Let start observing that the reconstructed parameters are better solving the problem only only using configurations belonging to the largest cluster.

Applying equations (11) and (12) both to the configurations in $C_1$ and $C_2$ according to remark 5.3, by formulas (18) and (19) we obtain the following reconstructed values of parameters:

$$J_{\text{exp}} = 2.0141 \pm 0.0802 \quad \text{and} \quad h_{\text{exp}} = -0.4196 \pm 0.0828.$$  \hfill (20)

Applying instead equations (11) and (12) only to the configurations in the largest cluster $C_1$, we obtain the following reconstructed values of parameters:
\[ J_{\text{exp}} = 2.0036 \pm 0.0353 \quad \text{and} \quad h_{\text{exp}} = -0.4091 \pm 0.0247. \] (21)

In order to justify our choice for the cutoff distance, we focus on figure 9, which shows the euclidean distances between \( J_{\text{exp}} \) and the true parameter \( J \) (blue stars) and between \( h_{\text{exp}} \) and \( h \) (red circles) for each choice of the cutoff distance \( d_c \), which takes value \( 10^{-j} \), for \( j = 1, \ldots, 6 \). The values of \( J_{\text{exp}} \) and \( h_{\text{exp}} \) are averaged across 20 \( M \)-samples. The errors are plotted as a function of \( d_c \).

\[ J_{\text{exp}} = 2.0036 \pm 0.0353 \quad \text{and} \quad h_{\text{exp}} = -0.4091 \pm 0.0247. \] (21)

In conclusion we have seen that in the case that the couple of parameters \((J, h)\) belongs to the region of metastability and is far enough from the coexistence line, at finite volume and at finite sample size, there are two clusters and one of them is much larger than the other one. According to remark 5.3, the obtained results confirm that the reconstruction of the parameters is better if we apply formulas (11) and (12) only to the largest cluster of configurations. The goodness of results is estimated comparing (20) and (21): the distance between the reconstructed parameters \( J_{\text{exp}} \) and the true value \( J \) is smaller in the second case, while the respective reconstructions of \( h \) are equivalent.

We proceede considering ten different couples of parameters which are nearby the coexistence line \( \Gamma(J, h) \) described above. In order to define them we take ten equispaced values for the imitation coefficient \( J \) in the interval \([1.6, 2]\) and we compute the corresponding values for the parameter \( J_{\text{exp}} \) using equations (18) and (19). The obtained values are shown in figure 10, where \( J_{\text{exp}} \) and \( h_{\text{exp}} \) are plotted as a function of \( J \).

In figure 11 we can see the results in reconstructing parameters crossing the coexistence line \( \Gamma(J, h) \). Fixed \( J = 1.8 \) we take increasing values of the parameter \( h \) in the interval \([-0.3940, \ldots, 0.3940]\) and we estimate the goodness of our results comparing (20) and (21). The obtained results confirm that in this case the reconstruction of the parameters is better if we apply formulas (11) and (12) only to the largest cluster of configurations.
In figure 12 we can see how the distribution of Gibbs of the monomer densities changes for different values of $h$. In figure 13 the euclidean distances between $J_{\text{exp}}$ and the value $J = 1.8$ (blue stars) and between $h_{\text{exp}}$ and $h \in [-0.3940, -0.3924]$ (red circles) are shown for each of the nine couples $(J, h)$. 

Figure 10. $N = 3000$, $J \in [1.6, 2]$, $h$ takes values over the coexistence line. Error bars are standard deviations on 20 different $M$ - samples of the same simulation. Parameters are reconstructed using the density clustering algorithm. Left panel: $J_{\text{exp}}$ (blue crosses) calculated from (18) as a function of $J$. The red continuous line represents the true value of $J$. Right panel: the value of $h_{\text{exp}}$ (blue crosses) calculated from (19) for the values of $J_{\text{exp}}$ in the left panel, as a function of $J$. The red continuous line corresponds to the exact value of $h$.

Figure 11. $N = 3000$, $J = 1.8$, $h \in [-0.3940, -0.3924]$. Error bars are standard deviations on 20 different $M$ - samples of the same simulation. Parameters are reconstructed using the density clustering algorithm. Left panel: the value of $J_{\text{exp}}$ (blue crosses) calculated from (18) as a function of $h$ together with the statistical error. The red continuous line represents the true value of $J$. Right panel: the value of $h_{\text{exp}}$ (blue crosses) calculated from (19) for the values of $J_{\text{exp}}$ in the left panel, as a function of $h$ together with the statistical error. The red continuous line corresponds to the exact value of $h$. 

$-0.3924]$. In figure 12 we can see how the distribution of Gibbs of the monomer densities changes for different values of $h$. 

In figure 13 the euclidean distances between $J_{\text{exp}}$ and the value $J = 1.8$ (blue stars) and between $h_{\text{exp}}$ and $h \in [-0.3940, -0.3924]$ (red circles) are shown for each of the nine couples $(J, h)$.
6. Conclusions and perspectives

In this paper the inverse problem for a mean-field monomer-dimer model has been investigated and solved. The method we proposed is based on the analytical inversion formula for the free parameters of the model, \( h \) and \( J \), that encode the local field and interaction strength.
for the local monomer number. Those two parameters are computed in terms of the first and second moment of the Boltzmann–Gibbs distribution and related to the observable data with the help of the maximum-likelihood function. In order to test the inversion method and its precision, we generated the statistical configurations of the model for different volumes and with different sample numbers obtaining the errors of the reconstruction. The standard inversion procedure produces good results when the statistics is robust for most of the values of the couple \((J, h)\). The model indeed is known to have a coexistence phase transition with a mean-field critical point and a coexistence line between the monomer and dimer phase. Close to the coexistence line the inversion method breaks down and it is necessary to separate (to cluster) the samples according to their bimodal distribution. We have shown that the modified clustering algorithm for the inversion recovers the parameters with the desired precision.

The clustering method is therefore particularly suitable for the analysis of real data where there is no \textit{a priori} knowledge of the phase space structure of the model and the data are initially used to determine indeed the class of models that describe the real system. We are currently investigating a database, similar to the one analysed in [17], where a clustering procedure is necessary to disentangle two different observed phases and we plan to perform an inverse problem procedure in a successive step.

Appendix A. Monomer-dimer model. Thermodynamic limit of the susceptibility

In this appendix, using the extended Laplace’s method studied in appendix B (see (B.1)), we prove that

\[
\lim_{N \to \infty} \frac{\partial}{\partial h} \langle m_N(J, h) \rangle = \frac{\partial}{\partial h} m(J, h).
\]

We have used this result in the fourth section.

\textbf{Theorem 1.} Given an imitative monomer-dimer model defined by a couple of parameters \((J, h)\) over a complete graph of \(N\) vertices, it holds:

\[
\lim_{N \to \infty} \frac{\partial}{\partial h} \langle m_N(J, h) \rangle = \frac{\partial}{\partial h} m(J, h).
\] \hfill (A.1)

\textbf{Remark 1.} According to results in [7], write the partition function of the monomer-dimer model as

\[
Z_N(J, h) = \int_{\mathbb{R}} e^{N F_N(x)} dx,
\]

where

\[
F_N(x) = -Jx^2 + p_N^{(0)}((2x - 1)J + h),
\] \hfill (A.2)
\[ p_N(J, h) = \frac{1}{N} \log \left( \int e^{NF_N(x)} \, dx \right). \]  
(A.3)

\[ p_N^{(0)}(J, h) = p_N(J, h) \big|_{J=0}. \]

Let \( c_N \) be the maximum point of the function \( F_N(x) \). In order to simplify the notations set 
\( \bar{x} := (2x - 1)J + h \) and \( \hat{c} := (1 - 2c)J + h \).

**Proof.** Let start computing the expectation of the monomer density using the definition of the pressure function given in (A.3):

\[ \langle m_N(J, h) \rangle = \frac{\partial p_N(J, h)}{\partial h} = \frac{1}{N \partial h} \log \left( \int e^{NF_N(x)} \, dx \right) = \frac{\int e^{NF_N(x)} \partial p_N^{(0)}(\bar{x}) \, dx}{\int e^{NF_N(x)} \, dx}. \]

The finite size susceptibility can be written as:

\[ \chi_N(J, h) = \frac{\partial \langle m_N(J, h) \rangle}{\partial h} = \frac{\int e^{NF_N(x)} \left[ N \left( \frac{\partial p_N^{(0)}(x)}{\partial h} \right)^2 + \frac{\partial^2 p_N^{(0)}(x)}{\partial h^2} \right] \, dx}{\int e^{NF_N(x)} \, dx} - N \left( \int e^{NF_N(x)} \, dx \right)^2 \left( \frac{\partial e^{NF_N(x)} \partial p_N^{(0)}(\bar{x}) \, dx}{\int e^{NF_N(x)} \, dx} \right)^2. \]  
(A.4)

\[ + \left[ \int e^{NF_N(x)} \left( \frac{\partial p_N^{(0)}(\bar{x})}{\int e^{NF_N(x)} \, dx} \right)^2 \, dx - \left( \int e^{NF_N(x)} \partial p_N^{(0)}(\bar{x}) \, dx \right)^2 \right]. \]  
(A.5)

Now we are going to use the extended Laplace’s method in order to evaluate the behavior of (A.4) and (A.5) at the thermodynamic limit.

Observe that, since all the quantities computed above are limited, the second order extended Laplace’s method given by (B.1) suffices to study the behavior of the finite size susceptibility as \( N \to \infty \).

As \( N \to \infty \), the numerator of (A.4) can be approximated as:

\[ \sqrt{\frac{2\pi}{-NF''(c)}} e^{NF_N(\infty)} \left\{ \frac{\partial^2 p_N^{(0)}(\bar{x})}{\partial h^2} \bigg|_{\bar{x}=\bar{c}} + \frac{1}{N} \left[ \frac{\partial^2 p_N^{(0)}(\bar{x})}{\partial h^2} \right|_{\bar{x}=\bar{c}} - \frac{\partial^2 p_N^{(0)}(\bar{x})}{\partial h^2} \right|_{\bar{x}=\bar{c}} \right\} \]

\[ + \frac{\partial^2 p_N^{(0)}(\bar{x})}{\partial h^2} \bigg|_{\bar{x}=\bar{c}} F''(c) + \frac{\partial^2 p_N^{(0)}(\bar{x})}{\partial h^2} \bigg|_{\bar{x}=\bar{c}} \frac{F''(c)}{2(F''(c))^2} = \frac{5 \partial^2 p_N^{(0)}(\bar{x})}{\partial h^2} \bigg|_{\bar{x}=\bar{c}} (F''(c))^2 \right\}. \]  
(A.6)
As $N \to \infty$, the numerator of the first fraction in (A.5) can be approximated as:

\[
\sqrt{\frac{2\pi}{-NF''(c)}} e^{NF_n(x)} \left\{ \left( \frac{\partial p^{(0)}(x)}{\partial h} \right)_{x=\bar{\epsilon}}^2 + \frac{1}{N} \left[ -\frac{d^2}{dx^2} \left( \frac{\partial p^{(0)}(x)}{\partial h} \right)_{x=\bar{\epsilon}}^2 \right] \right\}_{x=\bar{\epsilon}}^2 + \frac{d}{dx} \left( \frac{\partial p^{(0)}(x)}{\partial h} \right)_{x=\bar{\epsilon}}^2 \frac{F'''(c)}{2F''(c)} \right\} \right\}_{x=\bar{\epsilon}}^2 - \frac{5}{24F'''(c)^3} \left( F''(c) \right)^2 \right\}_{x=\bar{\epsilon}}^2.
\]

As $N \to \infty$, the numerator of the second fraction in (A.5) can be approximated as:

\[
\left( \sqrt{\frac{2\pi}{-NF''(c)}} e^{NF_n(x)} \left\{ \left( \frac{\partial p^{(0)}(x)}{\partial h} \right)_{x=\bar{\epsilon}}^2 + \frac{1}{N} \left[ -\frac{d^2}{dx^2} \left( \frac{\partial p^{(0)}(x)}{\partial h} \right)_{x=\bar{\epsilon}}^2 \right] \right\}_{x=\bar{\epsilon}}^2 + \frac{d}{dx} \left( \frac{\partial p^{(0)}(x)}{\partial h} \right)_{x=\bar{\epsilon}}^2 \frac{F'''(c)}{2F''(c)} \right\} \right\}_{x=\bar{\epsilon}}^2 - \frac{5}{24F'''(c)^3} \left( F''(c) \right)^2 \right\}_{x=\bar{\epsilon}}^2.
\]

As $N \to \infty$, the integral $\int_{\bar{\epsilon}} e^{NF_n(x)} dx$ can be approximated as:

\[
\left( \sqrt{\frac{2\pi}{-NF''(c)}} e^{NF_n(x)} \left\{ \left( \frac{\partial p^{(0)}(x)}{\partial h} \right)_{x=\bar{\epsilon}}^2 + \frac{1}{N} \left[ -\frac{d^2}{dx^2} \left( \frac{\partial p^{(0)}(x)}{\partial h} \right)_{x=\bar{\epsilon}}^2 \right] \right\}_{x=\bar{\epsilon}}^2 + 2 \frac{\partial p^{(0)}(x)}{\partial h} \left( \frac{\partial p^{(0)}(x)}{\partial h} \right)_{x=\bar{\epsilon}}^2 \frac{B(J, h)}{N} + \frac{B^2(J, h)}{N^2} \right\}_{x=\bar{\epsilon}}\right).
\]

\[
(A.8)
\]

Putting together (A.6) and (A.9) we obtain:

\[
(A.6) \xrightarrow{N \to \infty} g'(\bar{\epsilon}).
\]

Putting together (A.7)–(A.9), we obtain:

\[
(A.7) \xrightarrow{N \to \infty} \frac{-8F^2(g'(\bar{\epsilon}))^2}{2(-2J + 4Fg'(\bar{\epsilon}))}.
\]

\[
(A.11)
\]
Using (A.10) and (A.11), we find that as $N \to \infty$

$$\chi_N(J,h) \xrightarrow{N \to \infty} \frac{8J^2 (g')^2}{2(-2J + 4J^2 g')^2} = \frac{4J g'(1 - 2J g') + 8J^2 (g')^2}{4J(1 - 2J g')} = \frac{(g')^2}{1 - 2J g'}.$$  \hfill (A.12)

At the thermodynamic limit, the susceptibility is the partial derivative of the solution $m(J,h)$ of the consistency equation with respect to the parameter $h$, so that:

$$\chi = \frac{\partial m(J,h)}{\partial h} = \frac{d}{dh} g((2m - 1)J + h) \left(1 + 2 \frac{\partial m(J,h)}{\partial J} f\right)$$

$$= g'( (2m - 1)J + h)(1 + 2\chi J)$$

$$\Rightarrow \chi = \frac{(g')^2}{1 - 2J g'}.$$  

Hence, (A.1) is proved. \hfill $\square$

**Appendix B. Extended Laplace’s method. Control at the second order**

The usual Laplace method works with integrals of the form

$$\int_{\mathbb{R}} (\psi(x))^n u(x) dx$$

as $n \to \infty$. In this appendix we prove an extension at the second order of the previous method when the functions $\psi$ and $u$ may depend on $n$ (see [7] for the control at first order). We have used that in appendix A.

**Theorem 1.** For all $n \in \mathbb{N}$, let $\psi_n : \mathbb{R} \to \mathbb{R}$ and $u_n : \mathbb{R} \to \mathbb{R}$. Suppose that there exists a compact interval $K \subset \mathbb{R}$ such that $\psi_n, u_n > 0$ on $K$, so that in particular

$$\psi_n(x) = e^{\psi_n(x)} \quad \forall x \in K.$$  

Suppose that $f_n \in C^4(K)$ and that $u_n \in C^2(K)$.

Moreover suppose that

1. $f_n \xrightarrow{n \to \infty} f$ uniformly on $K$ with its derivatives;
2. $u_n \xrightarrow{n \to \infty} u$ uniformly on $K$ with its derivatives;
3. there exists a positive constant $c_1 < \infty$ such that $|u_n| < c_1$;
4. $\max_K f_n$ is attained in a unique point $c_n \in \text{int}(K)$;
5. $\max_K f$ is attained in a unique point $c \in \text{int}(K)$;
6. $\limsup_{n \to \infty} \left( \sup_{\mathbb{R}\setminus K} \log |\psi_n| - \max_K f_n \right) < 0$;
7. $f''(c) < 0$;
8. $\limsup_{n \to \infty} \int_{\mathbb{R}} |\psi_n(x)| dx < \infty$.

Then, as $n \to \infty$,  

$$\int_{\mathbb{R}} (\psi_n(x))^n u_n(x) dx = \sqrt{\frac{2\pi}{-n f''(c)}} e^{\psi_n(c)} \left\{ u(c) + \frac{\Lambda}{n} + o \left( \frac{1}{n} \right) \right\},$$  \hfill (B.1)
where

\[ \Lambda = \frac{-u''(c)}{2f''(c)} + \frac{u(c)f''(c)}{8(f''(c))^2} + \frac{u'(c)f'''(c)}{2(f''(c))^2} - \frac{5u(c)(f'''(c))^2}{24(f''(c))^3}. \]

In the proof we use the following elementary fact:

**Lemma 2.** Let \((f_n)_{n \in \mathbb{N}}\) be a sequence of continuous functions uniformly convergent to \(f\) on a compact set \(K\). Let \((I_n)_{n \in \mathbb{N}}\) and \(I\) be subsets of \(K\) such that

\[ \max_{x \in I_n, y \in I} \text{dist}(x, y) \to 0, \quad \text{as} \quad n \to \infty. \]

Then

(a) \( \max_{n \to \infty} f_n \to \max f \)

(b) \( \arg \max_{n \to \infty} f_n \to \arg \max f \), provided that \(f\) has a unique global maximum point on \(I\).

**Proof.** Since \(c_n\) is an internal point of maximum of \(f_n\) (hypothesis 4), \(f'_n(c_n) = 0\). Moreover \(\forall x \in K\)

\[ f_n(x) = f_n(c_n) + \frac{1}{2}f''_n(c_n)(x - c_n)^2 + \frac{1}{6}f'''_n(c_n)(x - c_n)^3 + \frac{1}{24}f''''_n(\xi_{x,n})(x - c_n)^4, \quad (B.2) \]

with \(\xi_{x,n} \in (c_n, x) \subset K\), and

\[ u_n(x) = u_n(c_n) + u'_n(c_n)(x - c_n) + \frac{1}{2}u''_n(\xi''_{x,n})(x - c_n)^2, \quad (B.3) \]

with \(\xi''_{x,n} \in (c_n, x) \subset K\).

Fix \(\epsilon = \epsilon_2\) and \(N_\epsilon\), such that \(|f^{(i)}(\xi) - f^{(i)}(\xi)| < \epsilon, i = 1, 2, 3, 4\) and \(|u^{(j)}(\xi) - u^{(j)}(\xi)| < \epsilon, j = 1, 2\ \forall \xi \in K\) and \(N_\epsilon\). Since \(f\) and \(u\) and their respective derivatives are continuous in \(c\), there exists \(\epsilon_2 > 0\) such that \(B(c, \epsilon_2) \subset K\) and \(\forall \xi : |\xi - c| < \epsilon_2\)

\[ |f^{(i)}(\xi) - f^{(i)}(c)| < \frac{\epsilon}{2}, i = 1, 2, 3, 4. \]

and

\[ |u^{(j)}(\xi) - u^{(j)}(c)| < \frac{\epsilon}{2}, j = 1, 2. \]

By lemma 2, \(c_n \to c\) because \(c\) is the unique maximum point of \(f\) on \(K\) (hypothesis 5). Thus there exists \(\epsilon_2\) such that

\[ |c_n - c| < \delta_e = \frac{\epsilon_2}{3} \quad \forall n > N_{\delta_e}, \quad (B.4) \]

Observe that by hypothesis 7 and for \(n > N_\epsilon \lor N_{\delta_e}, f''_n(c_n) < 0\).

Moreover, for \(n > N_\epsilon \lor N_{\delta_e}, \forall x \in B(c, \delta_e) \subset B(c, \delta_e)\) and \(\forall \xi_{x,n} \in (c_n, x) \subset K\), it holds:

\[ |\xi_{x,n} - c| \leq |\xi_{x,n} - x| + |x - c| \leq |c_n - x| + |x - c| \leq |c_n - c| + |c - x| + |x - c| < 3\delta_e = \epsilon_2 \]
\[ \Rightarrow \begin{cases} |f_n^{(j)}(\xi_{n,\eta}) - f^{(j)}(c)| \leq |f_n^{(j)}(\xi_{n,\eta}) - f^{(j)}(\xi_{n,\eta})| + |f^{(j)}(\xi_{n,\eta}) - f^{(j)}(c)| < \frac{\eta}{2} + \frac{\epsilon}{2} = \epsilon \\ |u_n^{(j)}(\xi_{n,\eta}) - u^{(j)}(c)| \leq |u_n^{(j)}(\xi_{n,\eta}) - u^{(j)}(\xi_{n,\eta})| + |u^{(j)}(\xi_{n,\eta}) - u^{(j)}(c)| < \frac{\eta}{2} + \frac{\epsilon}{2} = \epsilon \end{cases} \]

(B.5)

By substituting (B.5) in (B.2) and in (B.3), we obtain that for \( n \geq N_i \vee N_\delta \) and \( x \in B(c, \delta) \)

\[ f_n(x) \begin{cases} \leq f_n(c_n) + \frac{1}{2} f_n''(c_n)(x - c_n)^2 + \frac{1}{6} f_n'''(c_n)(x - c_n)^3 \\ + \frac{1}{24} (f^{(v)}(c) + \epsilon)(x - c_n)^4 \end{cases} \]

\[ \geq f_n(c_n) + \frac{1}{2} f_n''(c_n)(x - c_n)^2 + \frac{1}{6} f_n'''(c_n)(x - c_n)^3 \]

\[ + \frac{1}{24} (f^{(v)}(c) - \epsilon)(x - c_n)^4 \]  

(B.6)

and

\[ u_n(x) \begin{cases} \leq u_n(c_n) + u_n''(c_n)(x - c_n) + \frac{1}{2} (u_n''(c) + \epsilon)(x - c_n)^2 \\ \geq u_n(c_n) + u_n''(c_n)(x - c_n) + \frac{1}{2} (u_n''(c) - \epsilon)(x - c_n)^2 \end{cases} \]  

(B.7)

Now split the integral into two parts:

\[ \int_{\mathbb{R}} e^{\psi(x)} u_n(x) \, dx = \int_{\mathbb{R} \setminus B(c_n, \delta)} (\psi_n(x))^n u_n(x) \, dx + \int_{B(c_n, \delta)} e^{\psi(x)} u_n(x) \, dx. \]  

(B.8)

To control the first integral on the r.h.s. of (B.8) we claim that there exists \( \eta_{\delta_n} > 0 \) and \( \tilde{N}_{\delta_n} \) such that

\[ \log |\psi_n(x)| < f_n(c_n) - \eta_{\delta_n} \quad \forall x \in \mathbb{R} \setminus B(c_n, \delta) \quad \forall n > \tilde{N}_{\delta_n}; \]  

(B.9)

this implies that

\[ \limsup_{n \to \infty} \sup_{x \in \mathbb{R} \setminus B(c_n, \delta)} (\log |\psi_n(x)| - f_n(c_n)) < 0. \]

Indeed, using lemma 2:

\[ \limsup_{n \to \infty} \sup_{x \in \mathbb{R} \setminus B(c_n, \delta)} (\log |\psi_n(x)| - f_n(c_n)) \]

\[ = \left( \limsup_{n \to \infty} \sup_{x \in K \setminus B(c_n, \delta)} (f_n(x) - f_n(c_n)) \right) \vee \left( \limsup_{n \to \infty} \sup_{x \in \mathbb{R} \setminus K} (\log |\psi_n(x)| - f_n(c_n)) \right) \]

Moreover, since \( c \) is the unique maximum point of the continuous function \( f \) on the compact set \( K \),

\[ \sup_{x \in K \setminus B(c_n, \delta)} (f(x) - f(c)) < 0 \]

and this proves the claim.
Now using (B.9) and hypothesis 8 we can say that there exist $C_1$ and $N$ such that for all $n > N \vee \bar{N}_\delta$
\[
\int_{\mathbb{R} \setminus B(0, \delta)} e^{\text{R}_{(x)}} u_0(x) \, dx \leq e^{(\alpha - 1)(f_n(c_n) - \eta \delta_1)} \int_{\mathbb{R}} |\psi_n(x) \| u_n(x) \| \, dx
\]
\[
\leq e^{(\alpha - 1)(f_n(c_n) - \eta \delta_1)} \int_{\mathbb{R}} |\psi_n(x) | c_1 \, dx
\]
\[
\leq C_1 e^{(f_n(c_n) - \eta \delta_1)}. \quad \text{(B.10)}
\]

In order to find an upper bound for the second integral of the r.h.s. of (B.8), we proceed as follows:
\[
\int_{B(0, \delta)} e^{\text{R}_{(x)}} u_0(x) \, dx
\]
\[
\leq \int_{B(0, \delta)} e^{(f_n(c_n) + \frac{\delta_n}{6} (x - c_n)^2 + \frac{1}{2} f''(c_n)(x - c_n)^3 + \frac{1}{6} f'''(c_n)(x - c_n)^4) u_0(x) \, dx
\]
\[
= \int_{B(0, \delta)} e^{(f_n(c_n) + \frac{\delta_n}{6} (x - c_n)^2 + \frac{1}{2} f''(c_n)(x - c_n)^3 + \frac{1}{6} f'''(c_n)(x - c_n)^4)} u_0(x) \, dx. \quad \text{(B.11)}
\]

Since $\delta_1$ may be chosen small, the second exponential term can be expanded as
\[
\exp \left[ n \left( \frac{1}{6} f'''(c_n)(x - c_n)^3 + \frac{1}{24} (f'''(c_n) + \varepsilon)(x - c_n)^4 \right) \right]
\]
\[
\leq 1 + n \left( \frac{1}{6} f'''(c_n)(x - c_n)^3 + \frac{1}{24} (f'''(c_n) + \varepsilon)(x - c_n)^4 \right)
\]
\[
+ \frac{n^2}{12} \left( f'''(c_n) \right)^2(x - c_n)^6 + n^2 C_2 |x - c_n|^7, \quad \text{(B.12)}
\]

where $C_2$ is a positive real constant. Substitute (B.12) and (B.7) in (B.11). Collecting powers of $(x - c_n)$ and observing that odd powers don’t contribute to the integral, we claim that:
\[
\text{(B.11)} \leq e^{f_n(c_n)} \int_{B(0, \delta)} e^{\frac{\delta_n}{6} (x - c_n)^2} \left[ u_n(c_n) + (x - c_n)^2 u''(c) + \frac{\varepsilon}{2} \right]
\]
\[
+ (x - c_n)^4 \left( \frac{n u'(c_n) f'''(c_n)}{6} + u_n(c_n) (f'''(c_n) + \varepsilon) \right)
\]
\[
+ (x - c_n)^6 \left( \frac{n^2 u_n(c_n) f'''(c_n)}{144} + (u''(c) + \varepsilon) (f'''(c_n))^2 + u_n(c_n) C_2 \right) \, dx
\]
\[
+ e^{f_n(c_n)} \int_{B(0, \delta)} e^{\frac{\delta_n}{6} (x - c_n)^2} n^2 C_2 |x - c_n|^7 \, dx.
\]

Making the change of variable
\[
t = \sqrt{-n f''(c_n)} (x - c_n),
\]
we obtain:
\[
(B.11) \leq \frac{e^{\theta_0(c_n)}}{\sqrt{-nf''_n(c_n)}} \int_{B(0, \sqrt{-nf''_n(c_n)s_n})} e^{-\frac{\tau}{2} \left\{ u_n(c_n) + \frac{1}{n} \left[ -t^2 u''(c) + \epsilon \right] \right\}} \left[ e^{-\frac{1}{2} \left( \frac{u''(c)}{6f''_n(c_n)} - \frac{uf''_n(c_n)}{24f''_n(c_n)^3} \right) - \frac{\epsilon}{2} f''_n(c_n) + \frac{u''(c)}{6f''_n(c_n)} + \frac{uf''_n(c_n)}{24f''_n(c_n)^3} + \frac{u''(c)}{6f''_n(c_n)} } \right] \right\} dr \\
+ \frac{1}{n^2} \int_{B(0, \sqrt{-nf''_n(c_n)s_n})} e^{-\frac{\tau}{2} \left\{ u_n(c_n) + \frac{1}{n} \left[ -t^2 u''(c) + \epsilon \right] \right\}} \left[ e^{-\frac{1}{2} \left( \frac{u''(c)}{6f''_n(c_n)} - \frac{uf''_n(c_n)}{24f''_n(c_n)^3} \right) - \frac{\epsilon}{2} f''_n(c_n) + \frac{u''(c)}{6f''_n(c_n)} + \frac{uf''_n(c_n)}{24f''_n(c_n)^3} + \frac{u''(c)}{6f''_n(c_n)} } \right] \right\} dr \\
+ \frac{2}{n^2} \frac{e^{\theta_0(c_n)}}{n^2(f''_n(c_n))^3} \int_{B(0, \sqrt{-nf''_n(c_n)s_n})} e^{-\frac{\tau}{2} \left\{ u_n(c_n) + \frac{a^{(1)}_{n \epsilon}}{n} + \frac{b^{(1)}_{n \epsilon}}{n^2} \right\}} \right\} dr \\
+ \frac{2}{n^2} \frac{C_2 e^{\theta_0(c_n)}}{n^2(f''_n(c_n))^3} \int_{B(0, \sqrt{-nf''_n(c_n)s_n})} e^{-\frac{\tau}{2} t^2} \right\} dr.
\] (B.13)

where \(a^{(1)}_{n \epsilon}(t)\) and \(b^{(1)}_{n \epsilon}(t)\) are the arguments inside square brackets which are respectively multiplied by \(\frac{1}{\tau}\) and by \(\frac{1}{n^2}\).

In order to find a lower bound for the second integral of the r.h.s. of \((B.8)\), we proceed as follows:

\[
\int_{\mathbb{R}} (\psi_n(x))^n u_n(x) dx \\
\geq \int_{B(c_n, \delta_n)} e^{\theta_0(c_n) + \frac{1}{2} f''_n(c_n)(x-c_n)^2} e^{\left\{ \frac{1}{6} f''(c_n)(x-c_n)^3 + \frac{1}{24} f''(c_n)(x-c_n)^4 \right\}} u_n(x) dx.
\] (B.14)

Since \(\delta_n\) may be chosen small, the second exponential term satisfies

\[
\exp \left[ n \left\{ \frac{1}{6} f''(c_n)(x-c_n)^3 + \frac{1}{24} f''(c_n)(x-c_n)^4 \right\} \right] \\
\geq 1 + n \left\{ \frac{1}{6} f''(c_n)(x-c_n)^3 + \frac{1}{24} f''(c_n)(x-c_n)^4 \right\} \\
+ \frac{n^2}{72} (f''(c_n))^2 (x-c_n)^6 - n^2 C_3 |x-c_n|^7,
\] (B.15)

where \(C_3\) is a positive real constant.

Analogously as above, expand the second exponential term of \((B.14)\) as in \((B.12)\) and the function \(u_n(x)\) as in \((B.3)\). Collecting powers of \((x-c_n)\) and making the change of variable

\[
t = \sqrt{-nf''_n(c_n)}(x-c_n),
\]

we obtain:
\( (B.14) \geq \frac{e^{\psi(x,c)}}{\sqrt{-n f''_n(c_n)}} \int_{B(0,\sqrt{-n f''_n(c_n)})} e^{-\frac{x^2}{2}} \left\{ u_n(c_n) + \frac{1}{n} \left[ -r^2 u''(c) - \epsilon e^{-\frac{x^2}{2}} \right] + t^2 \left( \frac{u_n(c_n)(f^{(iv)}(c) - \epsilon)}{24 f''_n(c_n)} + \frac{u'_n(c_n) f''_n(c_n)}{6 (f''_n(c_n))^2} - \rho_n u_n(c_n) (f''_n(c_n))^2 \right] \right\} \ dr \\
+ \frac{1}{n^2} \left[ -r^2 (u''(c) - \epsilon) (f^{(iv)}(c) - \epsilon) \frac{48 (f''_n(c_n))^3}{48 (f''_n(c_n))^2} + t^8 \left( \frac{u''(c) - \epsilon) (f''_n(c_n))^2}{144 (f''_n(c_n))^4} - \frac{u'_n(c_n) C_3}{(f''_n(c_n))^2} \right) \right] \ dr \\
- 2 \frac{e^{\psi(x,c)}}{\sqrt{-n f''_n(c_n)}} \int_{B(0,\sqrt{-n f''_n(c_n)})} e^{-\frac{x^2}{2}} t^2 \frac{C_3}{n^{3/2} (f''_n(c_n))^{7/2}} \ dr \\
= \frac{e^{\psi(x,c)}}{n^2 (f''_n(c_n))^4} \int_{B(0,\sqrt{-n f''_n(c_n)})} e^{-\frac{x^2}{2}} t^2 \ dr \\
- 2 \frac{C_3 e^{\psi(x,c)}}{n^2 (f''_n(c_n))^4} \int_{B(0,\sqrt{-n f''_n(c_n)})} e^{-\frac{x^2}{2}} t^2 \ dr \\
(B.16) \)

where \( d_{n,\epsilon}^{(2)}(t) \) and \( b_{n,\epsilon}^{(2)}(t) \) are the arguments inside square brackets which are respectively multiplied by \( \frac{1}{n^2} \) and by \( \frac{1}{n^2} \).

It is easy to verify that:

\[
\int_{B(0,\sqrt{\pi n})} e^{-\frac{x^2}{2}} u_n(c_n) \ dr \xrightarrow{n \to \infty} \sqrt{2\pi} u(c). \\
\int_{B(0,\sqrt{\pi n})} e^{-\frac{x^2}{2}} t^2 \ dr \xrightarrow{n \to \infty} \int_{\mathbb{R}} e^{-\frac{x^2}{2}} t^2 \ dr = \sqrt{2\pi}(2k - 1)(2k - 3) \cdots (3)(1), \quad \forall k \in \mathbb{N}, \\
\int_{B(0,\sqrt{\pi n})} e^{-\frac{x^2}{2}} t^2 \ dr \xrightarrow{n \to \infty} \int_{0}^{\infty} e^{-\frac{x^2}{2}} t^2 \ dr = 48. \quad (B.17)
\]

In conclusion, using (B.8), (B.10), (B.13), (B.16) and (B.17), we obtain that for \( \epsilon \in (0, \epsilon_0] \) and \( n > N \vee N_{\epsilon} \vee \bar{N}_{\delta} \vee \bar{N}_{\bar{\delta}} \):

\[
\left\| \int_{\mathbb{R}} e^{-\frac{x^2}{2}} u_n(x) \ dx - \sqrt{\frac{2\pi}{n f''(c)}} e^{\psi(x,c)} u(c) \right\| \\
\leq \frac{1}{\sqrt{-n f''(c)}} \Delta \pi \\
\int_{B(0,\sqrt{-n f''(c)})} e^{-\frac{x^2}{2}} \left\{ u_n(c_n) + \frac{d_{n,\epsilon}^{(2)}(t)}{n} + \frac{b_{n,\epsilon}^{(2)}(t)}{n^2} \right\} \ dr \\
\xrightarrow{n \to \infty} \frac{2 \pi}{\sqrt{-n f''(c)}} \Delta \pi \\
+ \frac{2 \pi C_3}{\sqrt{-n f''(c)}} \int_{B(0,\sqrt{-n f''(c)})} e^{-\frac{x^2}{2}} t^2 \ dr + \frac{C_3}{\sqrt{-n f''(c)}} \ x \to 0 \\
\frac{n \to \infty}{\sqrt{\frac{2\pi}{\sqrt{-n f''(c)}}}} \\
(B.18)
\]

and
\[ \int_{B_n(t)} (\psi_n(x))^n u_n(x) \, dx - \sqrt{\frac{2\pi}{-\eta''(c) n}} e^{\eta_0(c)} u(c) \]

\[ \geq \frac{\int_{B_n(0, \sqrt{\eta''(c)n})} e^{\frac{1}{2} \left\{ u_n(c) + \frac{\delta_{n,c}}{\pi} + \frac{\delta_{n,c}}{2\pi} \right\}} \, dt}{\sqrt{\frac{-2\pi}{\eta''(c)}}} - \sqrt{\frac{2\pi}{-\eta''(c)}} u(c) \]

\[ \lim_{n \to \infty} \frac{\int_{B_n(0, \sqrt{\eta''(c)n})} e^{\frac{1}{2} \left\{ u_n(c) + \frac{\delta_{n,c}}{\pi} + \frac{\delta_{n,c}}{2\pi} \right\}} \, dt}{\sqrt{\frac{2\pi}{\eta''(c)}}} \to 1. \]  

(B.19)

Hence, by (B.18) and (B.19), (B.1) is proved.
