Non-abelian higher gauge theory
and categorical bundle

Abstract

A gauge theory is associated with a principal bundle endowed with a connection permitting to define horizontal lifts of paths. The horizontal lifts of surfaces cannot be defined into a principal bundle structure. An higher gauge theory is an attempt to generalize the bundle structure in order to describe horizontal lifts of surfaces. A such attempt is particularly difficult for the non-abelian case. Some structures have been proposed to realize this goal (twisted bundle, gerbes with connection, bundle gerbe, 2-bundle). Each of them uses a category in place of the total space manifold of the usual principal bundle structure. Some of them replace also the structure group by a category (more precisely a Lie crossed module viewed as a category). But the base space remains still a simple manifold (possibly viewed as a trivial category with only identity arrows). We propose a new principal categorical bundle structure, with a Lie crossed module as structure groupoid, but with a base space belonging to a bigger class of categories (which includes non-trivial categories), that we call affine 2-spaces. We study the geometric structure of the categorical bundles built on these categories (which is a more complicated structure than the 2-bundles) and the connective structures on these bundles. Finally we treat an example interesting for quantum dynamics which is associated with the Bloch wave operator theory.
1 Introduction

The geometry of principal bundles plays an important role in theoretical physics. It is the natural framework to model the fundamental interactions between point particles in classical field theory, and is the startpoint for the quantum field theory [1]. Moreover in nonrelativistic quantum physics, the geometric (Berry) phase phenomenon [2] is closely related to this geometry. A principal bundle naturally arises to treat cyclic quantum dynamics [3] or adiabatic quantum dynamics driven by classical parameters [4] [5] [6] [7]. These physical problems are associated with the holonomies or the horizontal lifts of paths drawn on the base manifold of the principal bundle.

The horizontal lifts of surfaces cannot be defined within the framework of principal bundles. The interest for the horizontal lifts of surfaces arises from the development of the string and brane theories, in which the string and brane gauge theory is associated with holonomies of surfaces [8] [9] [10] [11] [12]. Recently, we have shown that the geometric phases associated with quantum systems submitted to some decoherence processes take place in higher gauge theories [13] [14] [15].

Geometric realizations of abelian higher gauge theories are well understood, as gerbes with connection [16], bundle gerbes [17] or twisted bundles [18]. For the non-abelian higher gauge theories, some generalizations of these geometric realizations have been proposed: non-abelian gerbes with connection [19] [20], non-abelian bundle gerbes [22] [21] and non-abelian twisted bundles [22]. We can also cite the higher gauge structure arising in the study of the principal composite bundles [23]. In these approaches, the total space of the geometric structure is not a smooth manifold as in the usual gauge theory but a category. For some of these approaches, the structure group is also replaced by a structure which can be viewed as a category (as for example an extension of Lie groups). Another interesting approach of non-abelian higher gauge theories has been proposed by Baez et al and Wockel: the 2-bundles [24] [25] [26] [27]. In this approach, the structure group is replaced by a Lie crossed module. The different approaches seem to be equivalent [28]. The strategy followed by Baez et al to define the 2-bundles is very interesting since it is based on the idea consisting to substitute at each smooth manifold a geometric category called a 2-space. Unfortunately this goal seems unachieved since in the 2-bundle theory the base space is restricted to the trivial 2-spaces (a trivial 2-space is an usual manifold $M$ viewed as a category $\mathcal{M}$ with $\text{Obj} (\mathcal{M}) = M$ and $\text{Morph} (\mathcal{M}) = \{ \text{id}_x \}_{x \in M}$). The reason of this restriction is the difficulty to define a “2-cover” of a 2-space. Indeed the definition of the union of two open sub-2-spaces is not clear since it needs to know how to compose an arrow in one 2-space with an arrow in another one. The trivial 2-spaces are very poor categories since
they have only identity arrows.

In this paper, inspired by the 2-bundle theory, we propose a new theory of categorical bundles with a bigger class of 2-spaces that we call the affine 2-spaces. It includes the trivial 2-spaces but also categories with non-trivial arrows. Moreover the union of two affine open sub-2-spaces is clearly defined. The affine 2-spaces are introduced in the next section. Section 3 introduces the 2-bundles over affine 2-spaces and explores their algebraic and geometric properties. In particular we show that the structure is more rich than the usual 2-bundle theory, since a new kind of 1-transition functions appears. 2-bundles over affine 2-spaces are endowed with connective structures in section 4, and the horizontal lifts are considered in section 5. Finally section 6 presents a simple physical example based on the use of the Bloch wave operators and their generalizations in quantum dynamics.

A note about the notations used here: let $A$ be a category, $\text{Obj}(A)$ denotes its set of objects, $\text{Morph}(A)$ denotes its set of arrows (so called morphisms), $s : \text{Morph}(A) \to \text{Obj}(A)$ denotes its source map, $t : \text{Morph}(A) \to \text{Obj}(A)$ denotes its target map, $\circ : \text{Morph}(A) \times_{s=t} \text{Morph}(A) \to \text{Morph}(A)$ denotes the composition of the arrows and $\text{id} : \text{Obj}(A) \to \text{Morph}(A)$ denotes its identity map. Let $G$ be a Lie group, $e_G$ denotes its neutral element, $\text{Aut}(G)$ denotes its automorphisms group and $\text{Der}(g)$ denotes the algebra of the derivations of its Lie algebra $g$. Let $M$ be a differential manifold, $G_M$ denotes the set of $C^\infty$ functions from $M$ to $G$, $TM$ denotes the tangent space of $M$ and $\Omega^n(M,X)$ denotes the set of $X$ valued differential $n$-forms of $M$. Let $P$ be a principal bundle over $M$, $HP$ denotes the horizontal tangent space of $P$, $VP$ denotes the vertical tangent space of $P$ and $\Gamma(M,P)$ denotes the set of the sections from $M$ to $P$.

2 Affine 2-spaces

Definition 1 (2-space). A smooth 2-space is a category $\mathcal{M}$ such that $\text{Obj}(\mathcal{M})$ and $\text{Morph}(\mathcal{M})$ are smooth manifolds, and such that $s, t : \text{Morph}(\mathcal{M}) \to \text{Obj}(\mathcal{M})$, $\text{id} : \text{Obj}(\mathcal{M}) \to \text{Morph}(\mathcal{M})$ and $\circ : \text{Morph}(\mathcal{M}) \times_{s=t} \text{Morph}(\mathcal{M}) \to \text{Morph}(\mathcal{M})$ are smooth maps.

Definition 2 (Affine space). An affine space is defined by three kinds of data $(M, E, \varphi)$ where $M$ is a manifold, $E$ is a vector space and $\varphi : M^2 \to E$ is an application such that

i. $\forall x \in M, \varphi(x, x) = 0$.

ii. $\forall x, y, z \in M, \varphi(x, y) + \varphi(y, z) = \varphi(x, z)$.

iii. $\forall x \in M, \forall \mathbf{u} \in E, \exists y \in M$ such that $\varphi(x, y) = \mathbf{u}$.
An affine space is generally the consideration of a flat manifold where we indentify each of their tangent spaces with the set of bipoints. We want to extend this notion to more general situations.

**Definition 3 (Affine 2-space).** We call *affine 2-space* the three kinds of data \((\mathcal{M}, R, \varphi)\) where the category \(\mathcal{M}\) is a 2-space, \(R\) is a reflexive and symmetric relation on \(\text{Obj}(\mathcal{M})\) (if \(xRy\) we say that \(x\) and \(y\) are linkable) and \(\varphi: \bigsqcup_{n \in \mathbb{N}^*} \text{Obj}(\mathcal{M})^n/R \to \text{Morph}(\mathcal{M})\) is a surjective map where

\[
\text{Obj}(\mathcal{M})^n/R = \{(x_n, \ldots, x_1) \in \text{Obj}(\mathcal{M})^n | \forall i < n, x_{i+1}R x_i\}
\]

An affine 2-space is such that

0. \(\forall (y, \ldots, x) \in \text{Obj}(\mathcal{M})^n/R, s(\varphi(y, \ldots, x)) = x\) and \(t(\varphi(y, \ldots, x)) = y\).

i. \(\forall x \in \text{Obj}(\mathcal{M}), \varphi(x) = \text{id}_x\) and \(\forall (\ldots, x, x, \ldots) \in \text{Obj}(\mathcal{M})^n/R, \varphi(\ldots, x, x, \ldots) = \varphi(\ldots, x, \ldots)\).

ii. \(\forall (y, \ldots, x) \in \text{Obj}(\mathcal{M})^n/R, \forall (z, \ldots, y) \in \text{Obj}(\mathcal{M})^p/R, \varphi(z, \ldots, y) \circ \varphi(y, \ldots, x) = \varphi(z, \ldots, y, \ldots, x)\).

iii. \(\forall x \in \text{Obj}(\mathcal{M}), \forall f \in \text{Morph}(\mathcal{M})\) with \(s(f) = x\), \(\exists n \in \mathbb{N}^*, \exists (z, \ldots, x) \in \text{Obj}(\mathcal{M})^n/R\) such that \(\varphi(z, \ldots, x) = f\). Moreover, if \(n_0 = \min\{n \in \mathbb{N}^* | \exists (z, \ldots, x) \in \text{Obj}(\mathcal{M})^n/R\) such that \(\varphi(z, \ldots, x) = f\}\) then there exists only one \((z, \ldots, x) \in \text{Obj}(\mathcal{M})^n_0/R\) such that \(\varphi(z, \ldots, x) = f\).

The assumptions i., ii. and iii. are weaker versions of the corresponding assumptions in the definition of an affine space. If \(\forall x, y \in \text{Obj}(\mathcal{M})\) we have \(xRy\) we say that \(\mathcal{M}\) is totally linkable.

There are three important kinds of affine 2-spaces.

**Definition 4 (Euclidean affine 2-space).** An affine 2-space is said *euclidean* if \(R\) is transitive (\(R\) is then an equivalence relation) and if

\[
\forall (y, \ldots, x) \in \text{Obj}(\mathcal{M})^n/R, \varphi(y, \ldots, x) = \varphi(y, x)
\]

In the euclidean affine 2-space, the Chasles relation takes the same form than in the affine spaces

(1) \(\forall (x, y, z) \in \text{Obj}(\mathcal{M})^3/R, \varphi(z, y) \circ \varphi(y, x) = \varphi(z, x)\)

Moreover there is a bijection between \(\text{Morph}(\mathcal{M})\) and \(\text{Obj}(\mathcal{M})^2_0/R\).

**Definition 5 (Spherical affine 2-space).** An affine 2-space is said *spherical* if \(xRy \Rightarrow x = y\).

In a spherical affine 2-space the set of the arrows is reduced to \(\text{Morph}(\mathcal{M}) = \{\text{id}_x, x \in \text{Obj}(\mathcal{M})\}\) (a spherical affine 2-space is generally called a trivial 2-space).
Definition 6 (Hyperbolic affine 2-space). An affine 2-space is said hyperbolic if \( \forall n \in \mathbb{N}^*, \text{Obj}(\mathcal{M})^n_{/R} \neq \emptyset \) and \( \forall (y_1, ..., x_1), (y_2, ..., x_2) \in \bigsqcup_n \text{Obj}(\mathcal{M})^n_{/R}, \varphi(y_1, ..., x_1) = \varphi(y_2, ..., x_2) \Rightarrow (y_1, ..., x_1) \sim (y_2, ..., x_2) \) where \( \sim \) signifies that the two sequences are equal modulo consecutive repetitions \((..., x, x, ...) \sim (..., x, ...)\).

For a hyperbolic affine 2-space, there is a bijection between the set of the arrows and the set of the sorted collections of linkable objects without consecutive repetitions. We restrict our attention on these three cases.

We note that an affine space \((M, E, \varphi)\) can be viewed as a totally linkable euclidean affine 2-space \(\mathcal{M}\) with \(\text{Obj}(\mathcal{M}) = M\) and \(\text{Morph}(\mathcal{M}) = M \times E\) with \(s(x, u) = x, t(x, u) = y\) such that \(\varphi(x, y) = u, \text{id}_x = (x, 0)\) and \((\varphi(x, u), t) \circ (x, u) = (x, u + t)\).

The justification of the adjectives euclidean, spherical and hyperbolic is the following. Let \(\text{Obj}(\mathcal{M})\) be \(\mathbb{R}^2\), the sphere \(S^2\) or the Poincaré hyperbolic plane. Let \((D)\) be a geodesic of \(\text{Obj}(\mathcal{M})\) and \(R\) be such that \(xRy\) if and only if the geodesic joining \(x\) and \(y\) is parallel and not confused to \((D)\). Let \(\text{Morph}(\mathcal{M})\) be the set of the oriented piecewise geodesic paths with edges parallel and not confused to \((D)\). The affine 2-space \(\mathcal{M}\) is then:

- euclidean if \(\text{Obj}(\mathcal{M})\) is the plane (since it exists only one geodesic parallel to \((D)\) and passing through a point \(x \not\in (D)\));
- spherical if \(\text{Obj}(\mathcal{M})\) is the sphere (since it does not exit a geodesic parallel to \((D)\) and passing through a point \(x \not\in (D)\));
- hyperbolic if \(\text{Obj}(\mathcal{M})\) is the Poincaré plane (since it exists an infinity of geodesics parallel to \((D)\) and passing through a point \(x \not\in (D)\)).

Property 1. An arrow \(f \in \text{Morph}(\mathcal{M})\) of an affine 2-space has \(\varphi(s(f), t(f))\) as inverse if \(\mathcal{M}\) is euclidean, whereas if \(\mathcal{M}\) is hyperbolic then \(f\) is not invertible except if it is an identity arrow.

Proof. By definition for an euclidean affine 2-space, we have \(f = \varphi(t(f), s(f))\) and then \(f \circ \varphi(s(f), t(f)) = \varphi(t(f), s(f)) \circ \varphi(s(f), t(f)) = \varphi(t(f), t(f)) = \text{id}_{t(f)}\) and \(\varphi(s(f), t(f)) \circ f = \varphi(s(f), t(f)) \circ \varphi(t(f), s(f)) = \varphi(s(f), s(f)) = \text{id}_{s(f)}\).

For a hyperbolic affine 2-space, let \(f\) be an invertible arrow and \(f^{-1}\) be its inverse. There exists \((y, a, ..., b, x), (x, c, ..., d, y)\) such that \(\varphi(y, a, ..., b, x) = f\) and \(\varphi(x, c, ..., d, y) = f^{-1}\). We have then \(\varphi(y, a, ..., b, x) \circ \varphi(x, c, ..., d, y) = \varphi(y, a, ..., b, x, c, ..., d, y) = \varphi(y)\). We have then \((y, a, ..., b, x, c, ..., d, y) \sim y\) and then \(y = x = a = ... = b = c = ... = d\). \(\square\)

In order to enlighten the notation, the arrow \(\varphi(y, ..., x) \in \text{Morph}(\mathcal{M})\) of an affine 2-space will be denoted by \(\overleftarrow{y, ..., x}\). We write then \(\text{id}_x = \overleftarrow{x}\)} and
Let $\mathcal{M}$ be an affine 2-space, the category $\mathcal{U}$ such that $\text{Obj}(\mathcal{U})$ is an open submanifold of $\text{Obj}(\mathcal{M})$ and $\text{Morph}(\mathcal{U}) = \varphi \left( \bigcup_{n \in \mathbb{N}^*} \text{Obj}(\mathcal{U}) /_R^n \right)$ is called an open affine sub-2-space. By contrast with the generic 2-spaces, it is possible to define easily the union and the intersection of two open affine sub-2-spaces. Let $\mathcal{U}_1$ and $\mathcal{U}_2$ two open affine sub-2-spaces of $\mathcal{M}$. $\mathcal{U}_1 \cap \mathcal{U}_2$ and $\mathcal{U}_1 \cup \mathcal{U}_2$ are the open affine sub-2-spaces defined by

$$\text{Obj}(\mathcal{U}_1 \cap \mathcal{U}_2) = \text{Obj}(\mathcal{U}_1) \cap \text{Obj}(\mathcal{U}_2) \quad \text{Obj}(\mathcal{U}_1 \cup \mathcal{U}_2) = \text{Obj}(\mathcal{U}_1) \cup \text{Obj}(\mathcal{U}_2)$$

$$\text{Morph}(\mathcal{U}_1 \cap \mathcal{U}_2) = \varphi \left( \bigcup_{n \in \mathbb{N}^*} \left( \text{Obj}(\mathcal{U}_1) \cap \text{Obj}(\mathcal{U}_2) \right) /_R^n \right)$$

$$\text{Morph}(\mathcal{U}_1 \cup \mathcal{U}_2) = \varphi \left( \bigcup_{n \in \mathbb{N}^*} \left( \text{Obj}(\mathcal{U}_1) \cup \text{Obj}(\mathcal{U}_2) \right) /_R^n \right)$$

We can note that $\text{Morph}(\mathcal{U}_1) \cup \text{Morph}(\mathcal{U}_2) \subseteq \text{Morph}(\mathcal{U}_1 \cup \mathcal{U}_2)$. The composition of arrows belonging to two open affine sub-2-spaces is defined as follows:

Let $f \in \text{Morph}(\mathcal{U}_1)$ and $g \in \text{Morph}(\mathcal{U}_2)$ with $s(g) = t(f) = y \in \text{Obj}(\mathcal{U}_1) \cap \text{Obj}(\mathcal{U}_2)$, $g \circ f = \varphi(z, ..., y, ..., x)$ where $(y, ..., x)$ and $(z, ..., y)$ are the smaller collections of objects of $\mathcal{U}_1$ and $\mathcal{U}_2$ such that $\varphi(y, ..., x) = f$ and $\varphi(z, ..., y) = g$. We can then define a good open 2-cover of an affine 2-space $\mathcal{M}$ as being a set of open affine sub-2-spaces $\{\mathcal{U}_i\}$, such that $\{\text{Obj}(\mathcal{U}_i)\}_i$ is a good open cover of $\text{Obj}(\mathcal{M})$ (a set of contractible open sets such that $\bigcup_i \text{Obj}(\mathcal{U}_i) = \text{Obj}(\mathcal{M})$). An element $\mathcal{U}_i$ will be called a 2-chart. In order to enlighten the notation we will simply denote by $M = \text{Obj}(\mathcal{M})$ the manifold of objects of an affine 2-space, and by $\{U_i\}_i$ its good open cover.

## 3 Categorical principal bundles over affine 2-spaces

**Definition 7** (Lie crossed module). A Lie crossed module $\mathcal{G}$ is the four kinds of data $(G, H, t, \alpha)$ where $G$ and $H$ are Lie groups, $t : H \to G$ and $\alpha : G \to \text{Aut} H$ are homomorphisms such that $t$ is equivariant:

$$\forall g \in G, \forall h \in H \quad t(\alpha_g(h)) = gt(h)g^{-1}$$

and satisfies the Peiffer identity:

$$\forall h, h' \in H \quad \alpha_{ht}(h') = hh'h^{-1}$$

**Proposition 1** (A Lie crossed module as a category). A Lie crossed module is equivalent to a groupoid with $\text{Obj}(\mathcal{G}) = G$ and $\text{Morph}(\mathcal{G}) = H \rtimes G$ where
the semidirect product (called horizontal composition of arrows) is defined by
\[(h, g)(h', g') = (hα_g(h'), gg')\]
the identity, source and target maps are defined by
\[id_g = (e_H, g) \quad s(h, g) = g \quad t(h, g) = t(h)g\]
and the usual arrows composition (called vertical composition of arrows) is defined by
\[(h', t(h)g) \circ (h, g) = (h'h, g)\]

The Lie crossed modules are the categorical versions of the Lie groups.

**Definition 8** (Principal 2-bundle over an affine 2-space). Let \( M \) be an affine 2-space endowed with a 2-cover \( \{U^i\}_i \) and \( G \) be a Lie crossed module. A principal 2-bundle over \( M \) with structure groupoid \( G \) consists to a category \( P \) and a full functor \( π \in \text{Funct}(P, M) \) surjective on the objects such that:

- ∀\( i \), the categories \( U^i × G \) and \( π^{-1}(U^i) \) are naturally equivalent. We denote by \( φ^i : U^i × G \to π^{-1}(U^i) \) the equivalence (called local trivialisation) and by \( \bar{φ}^i : π^{-1}(U^i) \to U^i × G \) its weak inverse.
- The functors \( \text{Pr}_1 \bar{φ}^i \) and \( π \) restricted on \( π^{-1}(U^i) \) are equals.
- The fibration is compatible with the transitive right action of \( G \) on itself, i.e. ∀\( x \in U^i, ∀g, g' \in G \)

\[\bar{φ}^i φ^i(x, g)g' = \bar{φ}^i φ^i(x, gg')\]
where \( (x, g)g' = (x, gg') \).

We denote by \( κ^i : \text{Obj}(U^i × G) \to \text{Morph}(U^i × G) \) the natural equivalence between \( \text{id}_{U^i × G} \) and \( φ^i \bar{φ}^i \), and by \( \bar{κ}^i : \text{Obj}(π^{-1}(U^i)) \to \text{Morph}(π^{-1}(U^i)) \) the natural equivalence between \( \text{id}_{π^{-1}(U^i)} \) and \( φ^i \bar{φ}^i \):

\[∀(x, g) ∈ U^i × G, \quad s(κ^i_{2g}) = (x, g) \quad t(κ^i_{2g}) = φ^i \bar{φ}^i(x, g)\]
\[∀y...x ∈ \text{Morph}(M), ∀h ∈ H, ∀g ∈ G,\]
\[κ^i_{2g} h \circ (y...x, h, g) = φ^i \bar{φ}^i(y...x, h, g) \circ κ^i_{2g}\]
\[∀p ∈ \text{Obj}(P), \quad s(κ^i_p) = p \quad t(κ^i_p) = φ^i \bar{φ}^i(p)\]
\[∀f ∈ \text{Morph}(P), \quad κ^i_{s(f)} \circ f = φ^i \bar{φ}^i(f) \circ κ^i_{s(f)}\]

**Property 2.** There exists \( k^i ∈ \text{H}_{U^i} \) such that:
\[∀(x, g) ∈ U^i × G \]
\[φ^i \bar{φ}^i(x, g) = (x, t(k^i(x))g)\]
∀\bar{y}...x ∈ \text{Morph}(\mathcal{M}), ∀(h, g) ∈ H \rtimes G
(8) \quad \tilde{\phi}^i \phi^i(\bar{y}...\bar{x}, h, g) = (\bar{y}...\bar{x}, k^i(g)hkk^i(x))^{-1}, t(k^i(x))g)

∀p ∈ π^{-1}(U^i)
(9) \quad t(\bar{\kappa}_p^i) = \phi^i(x, t(k^i(x))g_p)

with p = \phi^i(x, g_p).

\textbf{Proof.} Since s(\kappa^i_{xg}) = (x, g), ∃\bar{k}^i_{xg} ∈ H and ∃(x_n, ..., x_1, x) such that \kappa^i_{xg} = (\bar{x}_n...\bar{x}, \bar{k}^i_{xg}, g). Since \kappa^i_{xg} = \tilde{\phi}^i \phi^i(x, g), we have \textit{x} = x and t(\bar{k}^i_{xg})g = g^i_x
with \tilde{\phi}^i \phi^i(x, g) = (x, g^i_x). Let k^i(x) = \bar{k}^i_{xg}. By definition of a 2-bundle we have \tilde{\phi}^i \phi^i(x, g) = \tilde{\phi}^i \phi^i(x, e_G)g \Rightarrow (x, t(k^i_{xg})g) = (x, t(k^i(x))g) and then ∀g ∈ G, k^i_{xg} = k^i(x) (modulo an ignored element of ker(t)) without relevant role because it is killed by the target map). We have then g^i_x = t(k^i(x))g.
This proves the first equality.

If \mathcal{M} is euclidean, then \bar{x}...\bar{x} = \bar{x}. If \mathcal{M} is spherical, \bar{x} is the only one arrow with source equal to \textit{x} (and with target equal to \textit{x}). We suppose now that \mathcal{M} is hyperbolic. \kappa^i is a natural equivalence, then \kappa^i_{xg} must be invertible. \bar{x}...\bar{x} must be then invertible, now the only invertible arrows of a hyperbolic affine 2-space are the identities, then \bar{x}...\bar{x} = \bar{x} also if \mathcal{M} is hyperbolic.

Let h ∈ H and \bar{\bar{y}}...\bar{x} ∈ \text{Morph}(U^i). Let \bar{h}^i_{\bar{y}...\bar{x}} ∈ H be such that \tilde{\phi}^i \phi^i(\bar{\bar{y}}...\bar{x}, h, g) = (\bar{\bar{y}}...\bar{x}, \bar{h}^i_{\bar{y}...\bar{x}}, g^i_x). From equation (10) we have
(10) \quad (\bar{\bar{y}}...\bar{x}, k^i(y), t(h)g) \circ (\bar{\bar{y}}...\bar{x}, h, g) = (\bar{\bar{y}}...\bar{x}, \bar{h}^i_{\bar{y}...\bar{x}}, g^i_x) \circ (\bar{x}, k^i(x), g)

and then
(11) \quad (\bar{\bar{y}}...\bar{x}, k^i(y)h, g) = (\bar{\bar{y}}...\bar{x}, \bar{h}^i_{\bar{y}...\bar{x}}k^i(x), g)

We conclude that \bar{h}^i_{\bar{y}...\bar{x}} = k^i(y)hk^i(x)^{-1}. This proves the second equality.

By definition t(\bar{\kappa}_p^i) = \phi^i \tilde{\phi}^i(p) = \phi^i \tilde{\phi}^i(x, g_p). The third equality comes from \phi^i \tilde{\phi}^i(x, g_p) = (x, t(k^i(x))g_p).

The natural equivalence is then \kappa^i_{xg} = (\bar{x}, k^i(x), g).

\textbf{Proposition 2} (Right actions on a principal 2-bundle). There is two right actions R, \bar{R} : H \rtimes G → \text{Funct}(\mathcal{P}, \mathcal{P}) of the Lie crossed module on a principal 2-bundle defined by:
∀p ∈ \text{Obj}(\mathcal{P}) with p = \phi^i(x, g_p)
(12) \quad R(h, g)p = \phi^i(x, g_p)g

∀f ∈ \text{Morph}(\mathcal{P}) with f = \phi^i(\bar{y}...\bar{x}, h_f, g_f)
(13) \quad R(h, g)f = \phi^i(\bar{y}...\bar{x}, h_f \alpha_{gf}(h), g_f)
∀p ∈ Obj(\mathcal{P}) with \phi^i(p) = (x, g_p)
(14) \bar{\phi}^i R(h, g)p = (x, g_p g)
∀f ∈ \text{Morph}(\mathcal{P}) with \bar{\phi}^i(f) = (\bar{f}_x, \bar{h}, \bar{g}_f)
(15) \bar{\phi}^i R(h, g)f = (\bar{f}_x, \bar{h} \alpha_{\bar{g}}(h), \bar{g}_f g)

Equivalently, \mathcal{R} and \bar{\mathcal{R}} are defined by the following commutative diagrams:

\[
\begin{array}{ccc}
\mathcal{U}^i \times \mathcal{G} & \xrightarrow{\phi^i} & \pi^{-1}(\mathcal{U}^i) \\
\downarrow \scriptstyle{(h,g)} & & \downarrow \scriptstyle{R(h,g)} \\
\mathcal{U}^i \times \mathcal{G} & \xleftarrow{\bar{\phi}^i} & \pi^{-1}(\mathcal{U}^i)
\end{array}
\]

Property 3. \forall (h, g) ∈ H \times G, \bar{R}(\alpha_{g^{-1}}(h^{-1}), g^{-1})R(h, g) is naturally equivalent to \text{id}_\mathcal{P}. Let \rho(h, g) : \text{Obj}(\mathcal{P}) → \text{Morph}(\mathcal{P}) be the associated natural equivalence. \forall p ∈ \text{Obj}(\mathcal{P}), s(\rho_p(h, g)) = p and \phi^i t(\rho_p(h, g)) = (x, t(k^i(x))g_p) with p = \phi^i(x, g_p).

∀(h, g) ∈ H \times G, R(h, g)\bar{R}(\alpha_{g^{-1}}(h^{-1}), 1, g^{-1}) is naturally equivalent to \text{id}_\mathcal{P}. Let \tilde{\rho}(h, g) : \text{Obj}(\mathcal{P}) → \text{Morph}(\mathcal{P}) be the associated natural equivalence. \forall p ∈ \text{Obj}(\mathcal{P}), s(\tilde{\rho}_p(h, g)) = \phi^i(x, t(k^i(x))\bar{g}_p) with \tilde{\phi}^i(p) = (x, \bar{g}_p) and t(\tilde{\rho}_p(h, g)) = p.

Proof. The natural equivalences follow from the following diagram:

\[
\begin{array}{ccc}
\mathcal{U}^i \times \mathcal{G} & \xleftarrow{\phi^i} & \pi^{-1}(\mathcal{U}^i) \\
\downarrow \scriptstyle{(\alpha_{g^{-1}}(h^{-1}), g^{-1})} & & \scriptstyle{R(h,g)} \downarrow \scriptstyle{R(\alpha_{g^{-1}}(h^{-1}), g^{-1})} \\
\mathcal{U}^i \times \mathcal{G} & \xleftarrow{\bar{\phi}^i} & \pi^{-1}(\mathcal{U}^i)
\end{array}
\]

where each double arrow is naturally equivalent to an identity.

By definition,
\[
t(\rho_p(h, g)) = \bar{R}(\alpha_{g^{-1}}(h^{-1}), g^{-1})R(h, g)p = \bar{R}(\alpha_{g^{-1}}(h^{-1}), g^{-1})\phi^i(x, g_p g)
\]
with p = \phi^i(x, g_p). We have then \bar{\phi}^i t(\rho_p(h, g)) = \bar{\phi}^i \bar{R}(\alpha_{g^{-1}}(h^{-1}), g^{-1})\phi^i(x, g_p g).

Since \bar{\phi}^i \phi^i(x, g_p g) = (x, t(k^i(x))g_p g) we have \bar{\phi}^i t(\rho_p(h, g)) = (x, t(k^i(x))g_p gg^{-1}).

By definition, s(\tilde{\rho}_p(h, g)) = R(h, g)\bar{R}(\alpha_{g^{-1}}(h^{-1}), g^{-1})p. Since
\[
\bar{\phi}^i \bar{R}(\alpha_{g^{-1}}(h^{-1}), g^{-1})p = (x, \bar{g}_p g^{-1})
\]
with \bar{\phi}^i(p) = (x, \bar{g}_p), we have
\[
\phi^i \bar{\phi}^i \bar{R}(\alpha_{g^{-1}}(h^{-1}), g^{-1})p = t(\bar{R}_\phi(x, \bar{g}_p g^{-1})) = \phi^i(x, t(k^i(x))\bar{g}_p g^{-1})
\]
By definition of $R$, we have $R(h, g)R(\alpha_g^{-1}(h^{-1}), g^{-1})p = \phi^i(x, t(k^i(x))g, g^{-1}g)$. 

**Definition 9** (G-transition functions). We define the G-transition functions of a principal 2-bundle as being $g^{ij} \in \mathcal{G}_{U^i \cap U^j}$ such that $\forall x \in U^i \cap U^j, \forall g \in G$

\[
\phi^i(x, g) = (x, g^{ij}(x)g)
\]

**Property 4.** The G-transition functions satisfy

\[
g^{ii}(x) = t(k^i(x)) g^{ji}(x) = t(k^j(x))g^{ij}(x)^{-1}t(k^i(x))
\]

**Proof.** $(x, g^{ii}(x)) = \phi^i(x, e_G) = (x, t(k^i(x)))$.

\[
\phi^i(x, e_G) = \phi^j(x, g_p) \Rightarrow \phi^i\phi^j(x, e_G) = \phi^i\phi^j(x, g_p)
\]

and then

\[
(x, t(k^i(x))) = (x, g^{ij}(x)g_p) \Rightarrow g_p = g^{ij}(x)^{-1}t(k^i(x))
\]

Finally

\[
\phi^i\phi^j\phi^i(x, e_G) = \phi^j(x, t(k^j(x)))g^{ij}(x)^{-1}t(k^i(x))) = (x, g^{ij}(x)t(k^j(x))g^{ij}(x)^{-1}t(k^i(x)))
\]

We conclude that $g^{ij}(x) = t(k^j(x))g^{ij}(x)^{-1}t(k^i(x))$. 

**Definition 10** (H-transition functions). We define the H-transition functions of a principal 2-bundle as being $h^{ij} \in \mathcal{H}_{(U^i \cap U^j)^2}$ such that $\forall y \in \mathcal{Morph}(U^i \cap U^j), \forall (h, g) \in H \times G$

\[
\phi^i(h, g) = (y \ldots x, (h^{ij}(y, x), g^{ij}(x)(h, g))
\]

The fact that $h^{ij}(y \ldots x)$ depends only from the source and the target of $y \ldots x$ (even if the affine 2-space is hyperbolic) is a consequence of the following property:

**Property 5.** The G-transition functions and the H-transition functions are related by $\forall x, y \in U^i \cap U^j$

\[
t(h^{ij}(y, x))g^{ij}(x) = g^{ij}(y)
\]
Proof. We have \( t(\phi^j \phi^j(y, e_H, e_G)) = \phi^i \phi^j(y, e_G) = (y, g^{ij}(y)) \). We have also \( t(\phi^j \phi^j(y, e_H, e_G)) = t(y, h^{ij}(y, x), g^{ij}(x)) = (y, t(h^{ij}(y, x))g^{ij}(x)) \). \( \square \)

In fact, we could have \( h^{ij}(y, x)\zeta^{ij}(z_n, ..., z_1) = h^{ij}(y, x)\zeta^{ij} \) with \( \zeta^{ij} \in \ker(t) \). Since \( \zeta^{ij} \) presents no relevant information (because it is killed by the target map), for the sake of simplicity we consider that \( \zeta^{ij} = e_H \). For the same reason we consider that \( h^{ij}(x, x) = e_H \), the \( H \)-transition functions are then trivial if the affine 2-space is spheric.

**Property 6.** The \( H \)-transition functions satisfy

\[
(20) \quad h^{ji}(y, x) = k^i(y)k^j(x)^{-1}
\]

\[
(21) \quad h^{ji}(y, x) = k^j(y)\alpha_{g^{ij}(x)^{-1}}(h^{ij}(y, x)^{-1}k^i(y)k^j(x)^{-1})k^j(x)^{-1}
\]

Proof.\[
(\tilde{y}...x, h^{ji}(y, x), g^{ji}(x)) = \tilde{\phi}^j \tilde{\phi}^i(\tilde{y}...x, e_H, e_G) = (x, k^i(y)k^j(x)^{-1}, t(k^j(x)))
\]

We have

\[
\tilde{\phi}^j \tilde{\phi}^i(\tilde{y}...x, e_H, e_G) = (\tilde{y}...x, h^{ij}(y, x)\alpha_{g^{ij}(x)}(h^{ji}(y, x), g^{ij}(x)g^{ji}(x))
\]

Moreover we have

\[
\tilde{\phi}^i \tilde{\phi}^j \tilde{\phi}^i(\tilde{y}...x, e_H, e_G) = \tilde{\phi}^i \tilde{\phi}^j(f)
\]

with \( f = \tilde{\phi}^i(\tilde{y}...x, e_H, e_G) \), but

\[
\tilde{\phi}^i \tilde{\phi}^j(f) = \tilde{\phi}^j(\tilde{K}_q \circ f \circ \tilde{K}_p^{-1})
\]

with \( p = \phi^i(x, e_G) \) and \( q = \phi^i(y, e_G) \).

\[
\tilde{\phi}^j(\tilde{K}_q \circ f \circ \tilde{K}_p^{-1}) = \tilde{\phi}^j(\tilde{y}...x, k^j(y)h_pk^i(x)^{-1}, t(k^j(x))g_p)
\]

with \( f = \phi^i(\tilde{y}...x, h_p, g_p) \).

\[
\phi^i(\tilde{y}...x, e_H, e_G) = \phi^i(\tilde{y}...x, h_p, g_p) \Rightarrow \tilde{\phi}^i(\tilde{y}...x, e_H, e_G) = \tilde{\phi}^i(\tilde{y}...x, h_p, g_p)
\]

and then

\[
(\tilde{y}...x, k^i(y)k^j(x)^{-1}, t(k^j(x))) = (\tilde{y}...x, h^{ij}(y, x)\alpha_{g^{ij}(x)}(h_p), g^{ij}(x)g_p)
\]

It follows that \( h_p = \alpha_{g^{ij}(x)^{-1}}(h^{ij}(y, x)^{-1}k^i(y)k^j(x)^{-1}) \). Finally we can identify \( h^{ij}(y, x)\alpha_{g^{ij}(x)}(h^{ji}(y, x)) \) with \( h^{ij}(y, x)\alpha_{g^{ij}(x)}(k^j(y)h_pk^j(x)^{-1}) \):

\[
\begin{align*}
& h^{ij}(y, x)\alpha_{g^{ij}(x)}(h^{ji}(y, x)) \\
& = h^{ij}(y, x)\alpha_{g^{ij}(x)}(k^j(y)\alpha_{g^{ij}(x)}(h^{ji}(y, x)))
\end{align*}
\]

\( \square \)
Property 7. We consider the sub-2-bundle $\pi^{-1}(U^i \cap U^j \cap U^k)$ at the intersection of three 2-charts. The functors $\tilde{\phi}^i_\phi \tilde{\phi}^j_\phi \tilde{\phi}^k_\phi$ and $\tilde{\phi}^i_\phi (\text{restricted on } U^i \cap U^j \cap U^k)$ are naturally equivalent.

Proof. This follows from the following commutative diagram:

\[
\begin{array}{ccc}
U^{ijk} \times G & \xrightarrow{\phi^k} & \pi^{-1}(U^{ijk}) \\
\downarrow & & \downarrow \\
U^{ijk} \times G & \xrightarrow{\phi^i} & \pi^{-1}(U^{ijk}) \\
\end{array}
\]

where $U^{ijk} = U^i \cap U^j \cap U^k$.

Let $\tilde{h}_{ij}^{jk} : \text{Obj}(U^i \cap U^j \cap U^k \times G) \rightarrow \text{Morph}(U^i \cap U^j \cap U^k \times G)$ be the associated natural equivalence:

\begin{align*}
(22) & \quad s(\tilde{h}_{ij}^{jk} ) = \tilde{\phi}^i_\phi \tilde{\phi}^j_\phi \tilde{\phi}^k_\phi(x, g) = (x, g^{ij}(x)g^{jk}(x)g) \\
(23) & \quad t(\tilde{h}_{ij}^{jk} ) = \tilde{\phi}^i_\phi \tilde{\phi}^j_\phi \tilde{\phi}^k_\phi(x, g) = (x, g^{jk}(x)g) \\
(24) & \quad \tilde{h}_{ij}^{jk}(y_{ij}h_g) \circ \tilde{\phi}^i_\phi \tilde{\phi}^j_\phi \tilde{\phi}^k_\phi(y_{ij...x}, h, g) = \tilde{\phi}^i_\phi \tilde{\phi}^j_\phi \tilde{\phi}^k_\phi(y_{ij...x}, h, g) \circ \tilde{h}_{ij}^{jk}
\end{align*}

Let $h^{ijk}(x) \in H$ be such that

\begin{equation}
(25) \quad \tilde{h}_{ij}^{jk} = (\gamma, h^{ijk}(x), g^{ij}(x)g^{jk}(x))
\end{equation}

Since $t(\tilde{h}_{ij}^{jk}) = (x, g^{jk}(x))$ we have $g^{jk}(x) = t(h^{ijk}(x))g^{ij}(x)g^{jk}(x)$.

Definition 11 (2-transition functions). We define the 2-transition functions of a principal 2-bundle as being $h^{ijk} \in \prod_{U^i \cap U^j \cap U^k} U^{ijk}$ such that $\forall x \in U^i \cap U^j \cap U^k$

\begin{equation}
(26) \quad t(h^{ijk}(x))g^{ij}(x)g^{jk}(x) = g^{jk}(x)
\end{equation}

The 2-transition functions measure then the obstruction to lift $\mathcal{P}$ as an usual principal bundle, since they characterize the failure of the cocycle relation for the $G$-transition functions. We can remark that

\begin{align*}
(27) & \quad h^{ij}(x) = \alpha_{g^{ij}(x)}(k^j(x)^{-1}) \\
(28) & \quad h^{ij}(x) = k^l(x)^{-1} \\
(29) & \quad h^{iij}(x) = \alpha_{g^{ij}(x)}(k^j(x)^{-1})
\end{align*}

Property 8. The natural equivalence $\tilde{h}_{ij}^{jk}$ for some $g \in G$ is

\begin{equation}
(30) \quad \tilde{h}_{ij}^{jk} = (\gamma, h^{ijk}(x), g^{ij}(x)g^{jk}(x)g)
\end{equation}
Proof. Let \( \tilde{h}^{ijk} \in H \) be such that \( \tilde{h}^{ijk} = (\overline{x}, \hat{h}^{ijk}, g^{ij}(x)g^{ik}(x)g) \). We have then \( t(\hat{h}^{ijk}g^{ij}(x)g^{ik}(x)g) = g^{ik}(x)g \) and \( g^{ik}(x) = t(h^{ijk}(x))g^{ij}(x)g^{ik}(x) \). \( \square \)

**Property 9.** The 2-transition functions measure also the failure of the cocycle relation for the \( H \)-transition functions in the following sense:

\[
(31) \quad h^{ij}(y, x)\alpha_{g^{ij}(x)}(h^{jk}(y, x)) = h^{ijk}(y)^{-1}h^{jk}(y, x)h^{ij}(x)
\]

**Proof.** By using the definition of \( \hat{h}^{ijk} \) and the expressions of \( \overline{\phi}^j \phi^j \overline{\phi}^k(\overline{y} \ldots \overline{x}, e_H, e_G) \) and of \( \overline{\phi}^j \phi^k(\overline{y} \ldots \overline{x}, e_H, e_G) \), we find

\[
(\overline{y}, h^{ijk}(y), g^{ij}(y)g^{ik}(y)) \circ (\overline{y} \ldots \overline{x}, h^{ij}(y, x)\alpha_{g^{ij}(x)}(h^{jk}(y, x)), g^{ij}(x)g^{jk}(x)) = (\overline{y} \ldots \overline{x}, h^{ik}(y, x), g^{ik}(x)g^{jk}(x))
\]

By composing the arrows, we find

\[
(\overline{y} \ldots \overline{x}, h^{ijk}(y)h^{ij}(y, x)\alpha_{g^{ij}(x)}(h^{jk}(y, x)), g^{ij}(x)g^{jk}(x)) = (\overline{y} \ldots \overline{x}, h^{ik}(y, x)h^{ijk}(x), g^{ik}(x)g^{jk}(x))
\]

\( \square \)

Since \( \tilde{h}^{ijk} \) is a natural equivalence, it has an inverse \( \tilde{h}^{ijk-1} \) such that \( \forall x \in U^j \cap U^j \cap U^k \) and \( \forall g \in G, \tilde{h}^{ijk-1} \circ \tilde{h}^{ijk} = (\overline{x}, e_H, g^{ij}(x)g^{ik}(x)g) \). It is clear that \( \tilde{h}^{ijk-1} = (\overline{x}, h^{ijk}(x)^{-1}, g^{ik}(x)) \) where \( h^{ij}(x)^{-1} \) is the inverse of \( h^{ij}(x) \) in the group law sense.

**Property 10.** The 2-transition functions \( h^{ijk} \) can be viewed as the trivializations of the natural equivalence \( \tilde{\kappa}^j \) on \( U^i \cap U^j \cap U^k \) because we have

\[
(32) \quad (\overline{x}, h^{ijk}(x)^{-1}, g^{ik}(x)) = \overline{\phi}^j(\tilde{\kappa}^{jk}(x, e_G))
\]

**Proof.** By definition of \( \tilde{\kappa}^j \) we have

\[
\overline{\phi}^j \overline{\phi}^j \phi^k(\overline{y} \ldots \overline{x}, e_H, e_G) = \tilde{\kappa}^{jk}(x, e_G) = \overline{\phi}^j(\tilde{\kappa}^{jk}(x, e_G)) \circ \phi^k(\overline{y} \ldots \overline{x}, e_H, e_G) \circ \overline{\phi}^{jk}(x, e_G)
\]

We have then

\[
\overline{\phi}^i \overline{\phi}^j \phi^k(\overline{y} \ldots \overline{x}, e_H, e_G) = \overline{\phi}^i(\tilde{\kappa}^{ik}(x, e_G)) \circ \phi^k(\overline{y} \ldots \overline{x}, e_H, e_G) \circ \overline{\phi}^{ik}(x, e_G)
\]

By using the definition of \( \tilde{h}^{ijk} \) we have

\[
\tilde{h}^{ijk} \circ \overline{\phi}^i(\tilde{\kappa}^{ik}(x, e_G)) \circ \phi^k(\overline{y} \ldots \overline{x}, e_H, e_G) \circ \overline{\phi}^{ik}(x, e_G) = \overline{\phi}^j \phi^k(\overline{y} \ldots \overline{x}, e_H, e_G) \circ \tilde{h}^{ijk}
\]

We can conclude that

\[
\tilde{h}^{ijk} \circ \overline{\phi}^i(\tilde{\kappa}^{jk}(x, e_G)) = \text{id}_{\overline{\phi}^j(\tilde{\kappa}^{jk}(x, e_G))} \Rightarrow h^{ijk-1} = \overline{\phi}^j(\tilde{\kappa}^{jk}(x, e_G))
\]

\( \square \)
Property 11. The 2-transition functions obey to the generalized cocycle relation:

\[ h_{ijl}(x) \alpha_{g^{ij}(x)}(h_{jkl}(x)) = h_{ikl}(x) h_{ijk}(x) \]

Proof. This follows from the definition of the 2-transition functions:

\[ t(h_{ijl}(x)) (t(\alpha_{g^{ij}(x)}(h_{jkl}(x)))) g^{ij}(x) g^{jk}(x) g^{kl}(x) = t(h_{ijl}(x)) g^{ij}(x) t(h_{jkl}(x)) g^{jk}(x) g^{kl}(x) \]

and

\[ t(h_{ikl}(x)) t(h_{ijk}(x)) g^{ij}(x) g^{jk}(x) g^{kl}(x) = t(h_{ikl}(x)) g^{ik}(x) g^{kl}(x) = g^{il}(x) \]

4 2-connections

The definition of a connective structure on a principal 2-bundle over an affine 2-space needs to introduce the “Lie algebra like” of a Lie crossed bundle. After this, before to consider the generic 2-connections, it is instructive to study the case of a trivial 2-bundle.

4.1 Differential Lie crossed module

Definition 12 (Differential Lie crossed module). Let \( G = (G, H, t, \alpha) \) be a Lie crossed module. The differential Lie crossed module associated with \( G \) is the four kinds of data \((\mathfrak{g}, \mathfrak{h}, t^{\text{Lie}}, \alpha^{\text{Lie}})\) where \( \mathfrak{g} \) and \( \mathfrak{h} \) are the Lie algebras of \( G \) and \( H \), and \( t^{\text{Lie}} : \mathfrak{h} \to \mathfrak{g} \) and \( \alpha^{\text{Lie}} : \mathfrak{g} \to \text{Der}(\mathfrak{h}) \) are the maps induced by \( t \) and \( \alpha \) in the Lie algebras, so

\[ \forall X \in \mathfrak{g}, \forall Y \in \mathfrak{h}, \quad t^{\text{Lie}}(\alpha^{\text{Lie}}(Y)) = [X, t^{\text{Lie}}(Y)] \]

and

\[ \forall Y, Y' \in \mathfrak{h}, \quad \alpha^{\text{Lie}}(Y')(Y') = [Y, Y'] \]

The semi-direct product of groups \( H \rtimes G \) induces a semi-direct sum of Lie algebras \( \mathfrak{h} \oplus \mathfrak{g} \) defined as being \( \mathfrak{h} \oplus \mathfrak{g} \) (the exterior direct sum being between the vector spaces without the algebra structures) endowed with the Lie braket \([,]_s\) such that

\[ \forall X, X' \in \mathfrak{g}, \quad [X, X']_s = [X, X']_g \in \mathfrak{g} \]

\[ \forall Y, Y' \in \mathfrak{h}, \quad [Y, Y']_s = [Y, Y']_h \in \mathfrak{h} \]

\[ \forall X \in \mathfrak{g}, \forall Y \in \mathfrak{h}, \quad [X, Y]_s = -[Y, X]_s = \alpha^{\text{Lie}}(Y) \in \mathfrak{h} \]
To simplify the notation, we denote all the Lie brackets by $[,]$ without subscript.
In the following, we denote by $\pi^\theta : h \in g \to g$ the projection induced by the canonical projection $h \oplus g \to g$ defined by the exterior direct sum of vector spaces.

Moreover, in order to simplify the notations, we will denote the adjoint representation of $H \times G$ on $h \in g$ by
\begin{equation}
\forall h \in H, \forall g \in G, \forall X \in h \in g, \quad \text{Ad}(h,g)X = hgXg^{-1}h^{-1}
\end{equation}
This notation is in accordance with the semi-direct product since $P \times K$ being not necessary faithful, we require only a notion of compatibility between two connections:

\begin{equation}
\text{Ad}(h_2,g_2)\text{Ad}(h_1,g_1)X = h_2g_2h_1g_1Xg_1^{-1}h_1^{-1}g_2^{-1}h_2^{-1}
\end{equation}
with the following convention $\text{Ad}(\alpha_g(h),g')X = ghg^{-1}g'Xg^{-1}gh^{-1}g^{-1}$.

\subsection{The notion of compatible connections}

Before to examine the possibility to endow a trivial 2-bundle with a connective structure, we need a simple lemma.

\textbf{Lemma 1.} Let $P$ be a principal $G$-bundle ($G$ is a Lie group) over a manifold $M$ with transition functions $g^i$. Let $f : G \to K$ be a group homomorphism. The left action of $K$ on itself defines a left action of $G$ on $K : f(g)k$, $k \in K$ and $g \in G$. The associated bundle $P \times_G K = \{(pg,f(g^{-1})k), g \in G\}_{p \in P, k \in K}$ constitutes a principal $K$-bundle over $M$ with transition functions $f(g^i)$.

\textit{Proof.} Let $\{U^i\}_i$ be a good open cover of $M$, and $\phi^i : U^i \times G \to P_{U^i}$ be the local trivializations of $P$. Let $\tilde{\phi}^i : U^i \times K \to (P \times_G K)_{U^i}$ be the local trivializations of $P \times_G K$: $\tilde{\phi}^i(x,k) = [(\phi^i(x,g), f(g^{-1})k); g \in G]$. Since $\phi^i(x,g) = \phi^i(x,g^i(x)g)$ (for $x \in U^i \cap U^{i'}$), we have $\tilde{\phi}^i(x,k) = [\tilde{\phi}^i(x,g^i(x)g), f(g^{-1})k); g \in G]$. By the variable change $\tilde{g} = g^i g$ we have

$\tilde{\phi}^i(x,k) = [(\phi^i(x,\tilde{g}), f(\tilde{g}^{-1})f(g^i(x)k); \tilde{g} \in G] = \tilde{\phi}^i(x,f(g^i)k)$

\hfill \Box

We want endow $P \times_G K$ with a connection which would be viewed as an image of a connection of $P$. The action of $G$ on $K$ being not necessary faithful, we require only a notion of compatibility between two connections:
**Definition 13** (Compatible connections). Let $HP$ and $H(P \times_{G,f} K)$ be connections (horizontal tangent spaces) of $P$ and $P \times_{G,f} K$. Let $j : P \to P \times_{G,f} K$ be the map defined by $\forall p \in P$, $j(p) = [(pg, f(g^{-1})); g \in G]$, i.e. $j(P) = P \times_{G,f} \{e_K\} \subset P \times_{G,f} K$. We say that the two connections are compatible if $j^*H_P = H_{ij}q(P \times_{G,f} K)$, where $j_*$ is the push-forward of $j$. Let $\omega \in \Omega^1(P, g)$ and $\tilde{\omega} \in \Omega^1(P \times_{G,f} K, \mathfrak{t})$ be the associated connection 1-forms ($\ker \omega = HP$), we have then $j^*\tilde{\omega} = f^{\text{Lie}}(\omega) \in \Omega^1(P, \mathfrak{t})$ where $f^{\text{Lie}}$ is Lie algebra homomorphism induced by $f$ and $j^*$ is the pull-back of $j$.

### 4.3 2-connection on a trivial 2-bundle

We consider a principal $G$-2-bundle $P$ over an affine 2-space $M$. In this section we suppose that $P$ is trivial, in the sense where its 2-transition functions are trivial : $h^{ij}(x) = e_H$. In that case, the $G$-transition functions satisfy the cocycle relation $g^{ij}(x)g^{jk}(x) = g^{ik}(x)$ ($\forall x \in U^i \cap U^j \cap U^k$) and define then a principal $G$-bundle $P$. We call it the object-bundle. The $H$-transition functions satisfy $h^{ij}(y, x)g^{ij}(x) = h^{ik}(y, x)$ ($\forall x \in U^i \cap U^j \cap U^k$).

Let $q^{ij}(y, x) = (h^{ij}(y, x), g^{ij}(x)) \in H \rtimes_{(U^i \cap U^j)^2} G$. We see that $q^{ij}$ satisfy the cocycle relation $q^{ij}(y, x)q^{jk}(y, x) = q^{ik}(y, x)$ ($\forall x, y \in U^i \cap U^j \cap U^k$). $q^{ij}$ can be then viewed as the transition functions of $Q$ a principal $H \times G$-bundle over $M^2_\Delta = \bigcup (U^i \times U^i)/\mathcal{R} \subset M^2/\mathcal{R}$. We call it the arrow-bundle. We denote by $\pi_P$ and $\pi_Q$ the projections of $P$ and $Q$.

\[
\phi : U^i \times G \to P_{\{U^i\}} \text{ being a functor, we have by definition}
\]
\[
\begin{align*}
\text{id}_{\phi(x, g)} &= \phi^i(\frac{1}{x}, e_H, g) \\
\text{s}(\phi^i(\frac{1}{x}, h, g)) &= \phi^i(x, g) \\
\text{t}(\phi^i(\frac{1}{x}, h, g)) &= \phi^i(y, t(h)g)
\end{align*}
\]

(36)

We want formulate these relations in the langage of the bundle theory in the case where $P$ is trivial.

Let $\Delta : M \to M^2_\Delta$ be the diagonal map. Let $\Delta^*Q = \{(x, q) \in M \times Q | \Delta(x) = \pi_Q(q)\}$ be the $H \times G$-bundle over $M$ induced by $Q$ via $\Delta$. By construction the transition functions of $\Delta^*Q$ are $g^{ij}_\Delta(x) = q^{ij}(\Delta(x)) = (e_H, g^{ij}(x))$. Clearly this is the transition functions of the widening of $P$, i.e. $P \times_G (H \times G)$ (where we have considered $G \simeq \{e_H\} \times G$ as a subgroup of $H \times G$, the isomorphism between $G$ and $\{e_H\} \times G$ constituting the homomorphism for the lemma[1]. We denote $I = \Delta^*Q = P \times_G (H \times G)$ and we call it the identity-bundle. Let $\Delta_* : (x, q) \mapsto q$ and $i : P \to I$ be
defined by $\forall p \in P, \iota(p) = [(pg, e_H, g^{-1}); g \in G]$. We have then the following commutative diagram

$$
P \xrightarrow{\iota} I \xrightarrow{\Delta^*} Q
$$

$$
M \xrightarrow{\Delta} M \xrightarrow{\Delta} M^2
$$

We denote by $\Delta_{ss} : TI \to TQ$ and by $\Delta^*_s : \Omega^*Q \to \Omega^*I$ the push-forward and the pull-back of $\Delta_s$, and by $\iota_* : TP \to TI$ and $\iota^* : \Omega^*I \to \Omega^*P$ the push-forward and the pull-back of $\iota$.

Let $\Pi_1 : M^2_\Delta \to M$. Let $\Pi_1^*P = \{(y, x, p) \in M^2_\Delta \times P | y = \pi_P(p)\}$ be the $G$-bundle over $M^2_\Delta$ induced by $P$ via $\Pi_1$. By construction the transition functions of $\Pi_1^*P$ are $g^{ij}_1(y, x) = g^{ij}(y)$. Let $t : H \rtimes G \to G$ be the homomorphism defined by $t(h, g) = t(h)g$. The bundle $Q \times_{H \rtimes G, t} G$ defined by $t$ and the lemma has the same transition functions $t(q^{ij}(y, x)) = t(h^{ij}(y, x))g^{ij}(x) = g^{ij}(x)$. We have then $T = \Pi_1^*P = Q \times_{H \rtimes G, t} G$ that we call the target-bundle. Let $\Pi_{1s} : (y, x, p) \mapsto p$ and $\tau : Q \to T$ be defined by $\forall q \in Q, \tau(q) = [(q(h, g), g^{-1}t(h^{-1})); h \in H, g \in G]$. We have then the following commutative diagram

$$
P \xleftarrow{\Pi_{1s}} T \xleftarrow{\tau} Q
$$

$$
M \xleftarrow{\Pi_1} M^2_\Delta \xleftarrow{\Delta} M^2_\Delta
$$

We denote by $\Pi_{1ss} : TT \to TP$ and by $\Pi_{1s}^* : \Omega^*P \to \Omega^*T$ the push-forward and the pull-back of $\Pi_{1s}$, and by $\tau_* : TQ \to TT$ and $\tau^* : \Omega^*T \to \Omega^*Q$ the push-forward and the pull-back of $\tau$.

Let $\Pi_2 : M^2_\Delta \to M$. Let $\Pi_2^*P = \{(y, x, p) \in M^2_\Delta \times P | x = \pi_P(p)\}$ be the $G$-bundle over $M^2_\Delta$ induced by $P$ via $\Pi_2$. By construction the transition functions of $\Pi_2^*P$ are $g^{ij}_2(y, x) = g^{ij}(x)$. Let $s : H \rtimes G$ be the homomorphism defined by $s(h, g) = g$. The bundle $Q \times_{H \rtimes G, s} G$ defined by $s$ and the lemma has the same transition functions $s(q^{ij}(y, x)) = g^{ij}(x).$ We have then $S = \Pi_2^*P = Q \times_{H \rtimes G, s} G$ that we call the source-bundle. Let $\Pi_{2s} : (y, x, p) \mapsto p$ and $\varsigma : Q \to S$ be defined by $\forall q \in Q, \varsigma(q) = [(q(h, g), g^{-1}); h \in H, g \in G]$. We have then the following commutative
We denote by $\Pi_2^{**} : TS \rightarrow TP$ and by $\Pi_2^* : \Omega^* P \rightarrow \Omega^* S$ the push-forward and the pull-back of $\Pi_2^*$, and by $\varsigma^* : TQ \rightarrow TS$ and $\varsigma^* : \Omega^* S \rightarrow \Omega^* Q$ the push-forward and the pull-back of $\varsigma$.

We denote by $\varphi_P^i$ and $\varphi_Q^i$ the transition functions of $P$ and $Q$ (they correspond respectively to the object and the arrow parts of the functor $\phi^i$).

The three previous commutative diagrams can be rewritten as follows:

\[
\begin{cases}
\Delta^* \circ \iota \left( \varphi_P^i(x, g) \right) = \varphi_Q^i(x, x, e_H, g) \\
\Pi_2^* \circ \varsigma \left( \varphi_Q^i(y, x, h, g) \right) = \varphi_P^i(x, g) \\
\Pi_1^* \circ \tau \left( \varphi_Q^i(y, x, h, g) \right) = \varphi_P^i(y, t(h)g)
\end{cases}
\]

This is the reformulation of the functor properties of $\phi^i$ in the fiber bundle language.

Since $P$ and $Q$ are principal bundles, they have canonical vertical tangent spaces: $T_pP \supset V_pP \simeq \mathfrak{g}$ ($\forall p \in P$) and $T_qQ \supset V_qQ \simeq \mathfrak{h} \oplus \mathfrak{g}$ ($\forall q \in Q$). We define a connection of $P$ as being two connections, one of $P$ and one of $Q$, compatible with the category structure of $P$, and then compatible with the commutative diagrams linking $P$ and $Q$ via $I$, $T$ and $S$.

**Definition 14** (2-connection on a trivial 2-bundle). A 2-connection on a trivial 2-bundle $P$, is the data of a connection $\omega_P$ on $P$ and a connection $\omega_Q$ on $Q$ such that the horizontal spaces satisfy

\[
\begin{align*}
\forall p \in P & \quad \Delta^* \circ \iota \omega_P = \omega_P & & (38) \\
\forall q \in Q & \quad \Pi_2^* \circ \varsigma \omega_Q = \omega_Q & & (39) \\
\forall q \in Q & \quad \Pi_1^* \circ \tau \omega_Q = \omega_Q & & (40)
\end{align*}
\]

This definition can be expressed in the terms of the connection 1-forms. Let $\omega_P \in \Omega^1(P, \mathfrak{g})$ be the connection 1-form of $P$ ($\ker \omega_P = H_P$) and $\omega_Q \in \Omega^1(Q, \mathfrak{h} \oplus \mathfrak{g})$ be the connection 1-form of $Q$ ($\ker \omega_Q = H_Q$). We have then:

\[
\begin{align*}
\iota^* \Delta^* \omega_Q & = \omega_P & & (41) \\
\varsigma^* \Pi_2^* \omega_P & = \pi^\mathfrak{h}(\omega_Q) & & (42) \\
\tau^* \Pi_1^* \omega_P & = \iota^\text{Lie}(\omega_Q) & & (43)
\end{align*}
\]
We consider now the local data of the connection. Let $\sigma^i_P \in \Gamma(U^i, P)$ be the trivializing local section of $P$

$$\forall x \in U^i \cap U^j, \quad \sigma^i_P(x) = \sigma^i_P(x)g^{ij}(x)$$

and $\sigma_Q^i \in \Gamma(U^i \times U^i, Q)$ be the trivializing local section of $Q$

$$\forall x, y \in U^i, \quad \sigma^i_Q(y, x) = \sigma^i_Q(y, x)q^{ij}(y, x)$$

By the properties of the local trivializations we have

$$\begin{align*}
\Delta_x \circ \iota(\sigma^i_P(x)) &= \sigma^i_Q(x, x) \\
\Pi_{2*} \circ \varsigma \left( \sigma^i_Q(y, x) \right) &= \sigma^i_P(x) \\
\Pi_{1*} \circ \tau \left( \sigma^i_Q(y, x) \right) &= \sigma^i_P(y)
\end{align*}$$

We can then define a $G$-gauge potential $A^i = \sigma^i_P \omega_P \in \Omega^1(U^i, g)$ and a $H \times G$-gauge potential $\eta^i = \sigma^i_Q \omega_Q \in \Omega^1(U^i \times U^i_R, h \oplus g)$. The relations between the connection 1-forms and between the trivializing local sections induce

$$\begin{align*}
\eta^i(x, x) &= A^i(x) \\
\pi^0(\eta^i(y, x)) &= A^i(x) \\
t^{Lie}(\eta^i(y, x)) &= A^i(y)
\end{align*}$$

This induces that $\eta^i(y, x) = A^i(x) + \eta^i(y, x)$ with $\eta^i \in \Omega^1(U^i \times U^i_R, h)$, such that $\eta^i(x, x) = 0$ and

$$t^{Lie}(\eta^i(y, x)) = A^i(y) - A^i(x) \in \Omega^1(U^i \times U^i_R, t^{Lie}(h))$$

By construction we have

$$\forall x \in U^i \cap U^j, \quad A^j(x) = g^{ij}(x)^{-1} A^i(x)g^{ij}(x) + g^{ij}(x)^{-1} dg^{ij}(x)$$

$$\forall x, y \in U^i \cap U^j, \quad \eta^j(y, x) = q^{ij}(y, x)^{-1} \eta^i(y, x)q^{ij}(y, x) + q^{ij}(y, x)^{-1} d_{(2)}q^{ij}(y, x)$$

where $d_{(2)} = d_x + d_y = \frac{\partial}{\partial x}dx^n + \frac{\partial}{\partial y}dy^n$ denotes the exterior differential of $M^2_\Delta$.

Property 12. $\forall x, y \in U^i \cap U^j$ we have

$$\alpha_{g^{ij}(x)}(\eta^j(y, x)) = h^{ij}(y, x)^{-1} \eta^i(y, x)h^{ij}(y, x)$$

$$+ h^{ij}(y, x)^{-1} d_{(2)}h^{ij}(y, x)$$

$$+ h^{ij}(y, x)^{-1} \alpha^{Lie}_{A^i(x)}(h^{ij}(y, x))$$
Proof. We have
\[
q^{ij-1}\eta^i q^{ij} = g^{ij-1}h^{ij-1}A^i h^{ij}g^{ij} + g^{ij-1}h^{ij-1}\eta^i h^{ij}g^{ij}
\]
\[
= g^{ij-1}A^i g^{ij} + g^{ij-1}h^{ij-1}[A^i, h^{ij}]g^{ij} + g^{ij-1}h^{ij-1}\eta^i h^{ij}g^{ij}
\]
Moreover
\[
q^{ij-1}d(2)g^{ij} = g^{ij-1}h^{ij-1}d(2)h^{ij}g^{ij} = g^{ij-1}(h^{ij-1}d(2)h^{ij})g^{ij} + g^{ij-1}dg^{ij}
\]
We have then
\[
\eta^i = g^{ij-1}A^i g^{ij} + g^{ij-1}dg^{ij} = g^{ij-1}(h^{ij-1}\eta^i h^{ij} + h^{ij-1}d(2)h^{ij} + h^{ij-1}[A^i, h^{ij}]) g^{ij}
\]
\[
\square
\]
Finally we can introduce the curvatures of the connections, \(F^i = dA^i + A^i \wedge A^j \in \Omega^2(U^j, g)\) and \(E^i = d(2)\eta^i + \eta^i \wedge \eta^j \in \Omega^2(U^i \times U^j_R, h \in g)\). It is easy to see that \(F^i\) can be decomposed as \(F^i = F^i + B^i\) with
\[
B^i = d(2)\eta^i + \eta^i \wedge \eta^j + \alpha^{Lie}_{A^i}(\eta^j) \in \Omega^2(U^i \times U^j_R, h)
\]
We can note that \(F^i\) is equivariant : \(\forall x, y \in U^i \cap U^j\)
\[
F^j = g^{ij-1}F^i g^{ij}
\]
but the curving satisfies
\[
\alpha_{g^{ij}}(B^j) = h^{ij-1}B^i h^{ij} + h^{ij-1} \alpha^{Lie}_{F^i}(h^{ij})
\]
In the higher gauge theory litterature, \(E^i\) (or \(F^i + t^{Lie}(B^i)\)) is usually called the fake curvature and \(B^i\) is usually called the curving. We can also introduce the true curvature (or 3-curvature) \(H^i = d(2)\eta^i + \alpha^{Lie}_{A^i}(B^i) = d(2)E^i + [A^i, E^i] = -[\eta^i, E^i] \in \Omega^3(U^i \times U^i_R, h)\) which satisfies the generalized Bianchi identity \(d(2)H^i + \alpha^{Lie}_{A^i}(H^i) + [B^i, E^i] = 0\).

If \(\mathcal{M}\) is hyperbolic, there exists also \(H \times G\)-bundles over \(M^n_\Delta = \bigcup (U^i)^n_R\) \((n \geq 3)\) denoted \(Q^{(n-1)}\) with the transition functions \(q^{ij}_{n-1}(z, ..., x) = q^{ij}(z, x)\). We consider the case of \(Q^{(2)}\). The relations between \(Q^{(2)}\) and \(P\) are the same than between \(Q\) and \(P\). Moreover \(Q^{(2)}\) is related to \(Q\) by the partial diagonal maps: \((y, x) \mapsto (y, y, x)\) and \((y, x) \mapsto (y, x, x)\). This induces that \(Q^{(2)}\) is endowed with a connection of gauge potential \(\eta^i \in \Omega^1((U^i)^2_R, h \in g)\) such
that

\begin{align*}
\eta^i(x, x, x) &= A^i(x) \\
\eta^i(y, x, x) &= \eta^i(y, x) \\
\eta^i(y, y, x) &= \eta^i(y, x)
\end{align*}

(57) \quad (58) \quad (59)

\begin{align*}
\ell^{Lie}(\eta^i(z, y, x)) &= A^i(z) \\
\pi^\theta(\eta^i(z, y, x)) &= A^i(x)
\end{align*}

(60) \quad (61)

This induces that \( \eta^i(z, y, x) = \eta^i(z, y) + \eta^i(y, x) - A^i(y) = \eta^i(z, y) + \eta^i(y, x) + A^i(x). \) The connection of \( Q^{(2)} \) does not contain new information. This argument can be repeated for \( Q^{(n>2)} \).

### 4.4 2-connection : general case

Let \( \{P^i_i\}_i \) and \( \{Q^i_i\}_i \) be the local principal \( G \)-bundles and \( H \rtimes G \)-bundles over \( U^j \) and \( U^j \times U^j \) defined by \( P^i = \{\phi^i(x, g); x \in U^i, g \in G\} \) and \( Q^i = \{\phi^i(y, x, h, g); (y, x) \in (U^i)^2, h \in H, g \in G\} \). The 2-transition functions \( h^{ijk}(x) \) constitute an obstruction to lift \( \{P^i_i\}_i \) and \( \{Q^i_i\}_i \) as globally defined principal bundles (because of the failure of the cocycle relations for \( g^{ij}(x) \) and \( h^{ij}(y, x) \)). The construction followed in the previous section can nevertheless be reiterated over each 2-chart \( U^j \) but not globally. We have then local identity-bundles \( I^i \), local target-bundles \( T^i \) and local source-bundles \( S^i \). Nevertheless we need a global bundle ensuring the global consistency of the connective structure. By definition of a Lie crossed module, \( t(H) \) is a normal subgroup of \( G \). We have then the following extension of groups:

\[
1 \to H \xrightarrow{\ell} G \xrightarrow{\pi} G/t(H) \to 1
\]

Let \( R \) be the principal \( G/t(H) \)-bundle over \( M \) defined by the transition functions \( \varphi(g^{ij}(x)) \) (since \( t(h^{ijk}(x)) \) is a subgroup, \( \varphi(g^{ij}(x)) \) satisfies the cocycle relation \( \varphi(g^{ij}(x)g^{jk}(x)) = \varphi(g^{ik}(x)) \)). Let \( P^i/t(H) \) be the principal \( G/t(H) \)-bundle over \( U^i \) induced by \( \varphi \) with \( P^i \). We denote by \( \delta^i: P^i \to P^i/t(H) \) the map defined by \( \forall p \in P^i, \delta^i(p) = pt(H) \) (where the canonical right action of \( G \) on \( P^i \) is simply denoted by a right multiplication). Clearly, \( P^i/t(H) \) and \( R \) are diffeomorphic over \( U^i: P^i/t(H) \simeq R_{|U^i} \). Moreover we have the
following commutative diagram over \( U^i \cap U^j \):

\[
\begin{array}{ccc}
P^j|_{U^i \cap U^j} & \xrightarrow{\phi^j \bar{\phi}^j} & P^i|_{U^i \cap U^j} \\
\varphi & \downarrow & \varphi \\
R|_{U^i \cap U^j} & \xrightarrow{\varphi_R \bar{\varphi}_R^{-1}} & R|_{U^i \cap U^j}
\end{array}
\]

where \( \varphi_R \) are the local trivializations of \( R \).

**Definition 15** (2-connection on a 2-bundle). A 2-connection on a 2-bundle \( \mathcal{P} \), is the data of connections \( HP^i \) on \( P^i \), connections \( HQ^i \) on \( Q^i \) and a connection \( HR \) on \( R \) such that the horizontal spaces satisfy

\[
\begin{align}
(62) & \quad \forall p \in P^i \quad \Delta_{\ast \epsilon_s} H_p P^i = H_{\Delta_{\ast \epsilon(p)}} Q^i \\
(63) & \quad \forall q \in Q^i \quad \Pi_{2 \ast \epsilon_s} H_q Q^i = H_{\Pi_{2 \ast \epsilon(q)}} P^i \\
(64) & \quad \forall q \in Q^i \quad \Pi_{1 \ast \epsilon_s} H_q Q^i = H_{\Pi_{1 \ast \epsilon(q)}} P^i \\
(65) & \quad \forall p \in P^i \quad \bar{\varphi}_R H_p P^i = H_{\bar{\varphi}(p)} R
\end{align}
\]

We can explain the relations between the connections by using the connection 1-forms \( \omega_p^i \in \Omega^1(U^i, g) \), \( \omega_Q^i \in \Omega^1(U^i \times U^i_{/R}, \mathfrak{h} \in g) \) and \( \omega_R \in \Omega^1(R, \mathfrak{g}_{\text{Lie}}(g)) \) (\( \mathfrak{g}_{\text{Lie}} : g \to g/\text{Lie}(h) \) is Lie algebra homomorphism induced by \( \phi \)):

\[
\begin{align}
(66) & \quad \iota^* \Delta_{\ast} \omega_Q^i = \omega_P^i \\
(67) & \quad \varsigma^* \Pi_{2 \ast} \omega_P^i = \pi^\theta(\omega_Q^i) \\
(68) & \quad \tau^* \Pi_{1 \ast} \omega_P^i = t_{\text{Lie}}(\omega_Q^i) \\
(69) & \quad \bar{\varphi}^* \omega_R = \mathfrak{g}_{\text{Lie}}(\omega_P^i)
\end{align}
\]

Let \( \sigma^i_P \in \Gamma(U^i, P^i) \) and \( \sigma^i_Q \in \Gamma(U^i \times U^i_{/R}, Q^i) \) be the trivializing local sections : \( \sigma^i_P(x) = \phi^i(x, e_G) \) and \( \sigma^i_Q(y, x) = \phi^i(\bar{y} x, e_H, e_G) \). We can define the G-gauge potential \( A^i = \sigma^i_P \omega_p^i \in \Omega^1(U^i, g) \) and the \( H \times G \)-gauge potential \( \eta^i = \sigma^i_Q \omega_Q^i \in \Omega^1(U^i \times U^i_{/R}, \mathfrak{h} \in g) \). By the same arguments that for the case of the trivial 2-bundles, we have \( \eta^i(y, x) = A^i(x) + \eta^i(y, x) \) with \( \eta^i \in \Omega^1(U^i \times U^i_{/R}, \mathfrak{h}) \) and \( t_{\text{Lie}}(\eta^i(y, x)) = A^i(y) - A^i(x) \).

Let the 1-form on \( U^i \cap U^j \) be defined by \( \sigma^i_P \omega_p^j - \sigma^j_P \bar{\phi}^j \phi^i \omega_p^i \). Since \( \phi^i \bar{\phi}^i \sigma^i_P(x) = \phi^i \bar{\phi}^j \phi^i_j(x, e_G) = \phi^i(x, g^i_j(x)) = R(g^i_j(x)) \sigma^i_P(x) \) we have

\[
(70) \quad \sigma^j_P \omega_p^j - \sigma^i_P \bar{\phi}^i \phi^i \omega_p^i = A^i(x) - g^i_j(x)^{-1} A^i(x) g^i_j(x) - g^i_j(x)^{-1} d g^i_j(x)
\]

But we have also

\[
(71) \quad \mathfrak{g}_{\text{Lie}}(\sigma^j_P \omega_p^j - \sigma^i_P \bar{\phi}^i \phi^i \omega_p^i) = \sigma^j_P \bar{\varphi}^j \omega_R - \sigma^i_P \bar{\phi}^i \phi^i \bar{\varphi}^i \omega_R
\]
But \(\partial^i\varphi^j\partial^i = \varphi_R^i\varphi_R^{i-1}\partial^j = \varphi^j\) and \(\partial^i\sigma^j_{\rho}(x) = \partial^i\sigma^j_{\rho}(x)\varphi^i_\rho(x)\). We have then
\[
\varphi^{Li\text{e}}(\sigma^j_{\rho}^{P} - \sigma^j_{\rho}^P) = a^i(x) - \varphi(g^{ij}(x))^{-1}a^i(x)\varphi(g^{ij}(x)) - \varphi(g^{ij}(x))^{-1}d\varphi(g^{ij}(x)) = 0
\]
where \(\varphi^j = \sigma^j_{\rho}^{P} - \sigma^j_{\rho}^P\) is the gauge potential of \(R\) associated with the section \(\vartheta^i\sigma^j_{\rho}(x) \in \Gamma(U^i, R)\). We conclude then that \(A^j(x) = g^{ij}(x)^{-1}A^i(x)g^{ij}(x) - g^{ij}(x)^{-1}dg^{ij}(x) \in \ker \varphi^{Li\text{e}} = t^{Li\text{e}}(\mathfrak{h})\).

**Definition 16** (potential-transformation). We call the potential-transformation of the 2-connection, the 1-form \(\eta^{ij} \in \Omega^1(U^i \cap U^j, \mathfrak{h})\) such that
\[
A^j(x) = g^{ij}(x)^{-1}A^i(x)g^{ij}(x) + g^{ij}(x)^{-1}dg^{ij}(x) + t^{Li\text{e}}(\eta^{ij}(x))
\]

The gluing relation of the \(P^i\)-curvatures is not equivariant:
\[
dA^j + A^j \wedge A^j = g^{ij-1}(dA^i + A^i \wedge A^i)g^{ij} + t^{Li\text{e}}(d\eta^{ij} + A^i_{\rho}(\eta^{ij}) - \eta^{ij} \wedge \eta^{ij})
\]
but \(\varphi^{Li\text{e}}(dA^i + A^i \wedge A^i)\) is equivariant (with \(\varphi(g^{ij})\)). Let \(B^i_{\text{sph}} \in \Omega^2(U^i, \mathfrak{h})\) be a 2-form such that
\[
B^i_{\text{sph}}(x) - \alpha_{g^{ij}(x)^{-1}}B^i_{\text{sph}}(x) = d\eta^{ij}(x) + A^i_{\rho}(\eta^{ij}(x)) - \eta^{ij}(x) \wedge \eta^{ij}(x)
\]
Then \(F^i = dA^i + A^i \wedge A^i - t^{Li\text{e}}(B^i_{\text{sph}}) \in \Omega^2(U^i, \mathfrak{g})\) is equivariant and belongs to the equivalence class of the 2-forms of \(P^i\) compatible with the curvature of \(R\) \((\varphi(F^i) = \varphi(dA^i + A^i \wedge A^i) = da^i + a^i \wedge a^i)\). We consider then \(F^i\) as being the fake curvature of \(\{P^i\}_i\). We call \(B^i_{\text{sph}}\) the spherical part of the curving.

**Property 13.** The gluing relation of the \(H \times G\)-gauge potential \(q^i \in \Omega^1(U^i \times U^j_{/R}, \mathfrak{h} \in \mathfrak{g})\) is
\[
q^i(y, x) = q^{ij}(y, x)^{-1}q^i(y, x)q^{ij}(y, x) + q^{ij}(y, x)^{-1}d_2q^{ij}(y, x)
+ t^{Li\text{e}}(\eta^{ij}(x)) + \eta^{ij}(y) - \eta^{ij}(x)
\]

**Proof.** Let \(\nu^{ij} \in \Omega^2((U^i \cap U^j)^2_{/R}, \mathfrak{h} \in \mathfrak{g})\) be \(\nu^{ij} = q^i - q^{ij-1}q^{ij}q^{ij-1}d_2q^{ij}\). By using the properties of \(\eta^i\) under the actions of \(\Delta^i, t^{Li\text{e}}\) and \(\pi^g\), and the gluing relation of \(A^i\) we find
\[
\nu^{ij}(x, x) = t^{Li\text{e}}(\eta^{ij}(x))
\]
\[
t^{Li\text{e}}(\nu^{ij}(y, x)) = t^{Li\text{e}}(\eta^{ij}(y))
\]
\[
\pi^g(\nu^{ij}(y, x)) = t^{Li\text{e}}(\eta^{ij}(x))
\]
This induces that \(\nu^{ij}(y, x) = t^{Li\text{e}}(\eta^{ij}(x)) + \eta^{ij}(y) - \eta^{ij}(x)\) (modulo an ignored element of \(\ker t^{Li\text{e}}\) without significance).
By following the same arguments as for a trivial 2-bundle, we have \( \eta^i(y, x) = A^i(x) + \eta^i(y, x), \) with \( \eta^i \in \Omega^1(U^i \times U^j_R, \mathfrak{h}) \) satisfying the gluing relation: \( \forall (x, y) \in (U^i \cap U^j) / \mathcal{R} \)

\[
\alpha_{g^{ij}(x)}(\eta^i(y, x)) = h^{ij}(y, x)^{-1} \eta^i(y, x) h^{ij}(y, x) \\
+ h^{ij}(y, x)^{-1} d(\partial) h^{ij}(y, x) \\
+ h^{ij}(y, x)^{-1} \alpha_{A^i(x)}(h^{ij}(y, x)) \\
+ \alpha_{\eta^{ij}(x)}(\eta^{ij}(y) - \eta^{ij}(x)) \\
(80)
\]

Let \( \mathcal{F}^i = d_{(2)} \mathcal{U}^i + \eta^i \wedge \eta^i \in \Omega^2(U^i \times U^j_R, \mathfrak{h} \in \mathfrak{g}) \) be the fake curvature. \( \mathcal{F}^i \) can be decomposed as \( \mathcal{F}^i = F^i + \mathcal{T}^i + B_{\text{sph}}^i + B_{\text{ns}}^i \) with \( B_{\text{sph}}^i = d(\partial) \eta^i + \eta^i \wedge \eta^i \) and \( \eta^i + \alpha_{A^i(x)}(\eta^i) \in \Omega^2(U^i \times U^j_R, \mathfrak{h}) \) called the nonspherical part of the curving. \( B_{\text{ns}}^i(x) + B_{\text{sph}}^i(y, x) \) forms the total curving. The gluing relation for the nonspherical part of curving is

\[
B_{\text{ns}}^i(y, x) = \alpha_{g^{ij}(x)}^{-1} \left( h^{ij}(y, x)^{-1} B_{\text{ns}}^i(y, x) h^{ij}(y, x) \\
+ h^{ij}(y, x)^{-1} \alpha_{\mathcal{T}^i(x)}(h^{ij}(y, x)) \right) \\
+ d\eta^{ij}(x) + \alpha_{A^i(x)}(\eta^{ij}(y)) - \eta^{ij}(y) \wedge \eta^{ij}(y) \\
- d\eta^{ij}(x) - \alpha_{A^i(x)}(\eta^{ij}(x)) + \eta^{ij}(x) \wedge \eta^{ij}(x) \\
+ [\eta^i(y, x), \eta^{ij}(y)] \\
(81)
\]

and for the total curving

\[
B^{ij}(y, x) = \alpha_{g^{ij}(x)}^{-1} \left( h^{ij}(y, x)^{-1} B^{ij}(y, x) h^{ij}(y, x) \right) \\
+ \alpha_{g^{ij}(x)}^{-1} \left( h^{ij}(y, x)^{-1} \alpha_{\mathcal{T}^i(x)} + B_{\text{sph}}^i(x) \right) ^{h^{ij}(y, x)} \\
+ d\eta^{ij}(y) + \alpha_{A^i(x)}(\eta^{ij}(y)) - \eta^{ij}(y) \wedge \eta^{ij}(y) \\
+ [\eta^i(y, x), \eta^{ij}(y)] \\
(82)
\]

**Property 14.** The gluing relation of the potential-transformation is \( \forall x \in U^i \cap U^j \cap U^k \)

\[
\alpha_{g^{ij}(\eta^{ij})} + \alpha_{g^{ij}(\eta^{jk})} - h^{ij} h^{jk} - \alpha_{g^{ik}(\eta^{ik})} h^{ijk} = h^{ijk} - \alpha_{A^i}^{h^{ij}} + h^{ijk} - \alpha_{A^i}^{h^{ij}} \]

\( (83) \)
Table 1. Local data of a 2-bundle with a 2-connection

|       | $M$ | $M_\Delta$ |
|-------|-----|------------|
| $G$   | $g^{ij}$ | $A^i$  |
|       |       | $F^i$     |
| $H$   | $h^{ijk}$ | $\eta^{ij}$ | $B^i_{sph}$ |
|       |       |           | $h^{ij}$ |
|       |       |           | $B^i_{ns}$ |

**Proof.**

\[
g_{ik} t^{Lie}(\eta^{ik}) g^{ik-1}
\]

\[
= g_{ik} A^k g^{ik-1} - A^i - dg_{ik} g^{ik-1}
\]

\[
= g_{ik} (g^{jk-1} A^j g^{jk} + g^{jk-1} dg^{jk} + t^{Lie}(\eta^{jk})) g^{ik-1} - A^i - dg_{ik} g^{ik-1}
\]

\[
= g_{ik} (g^{jk-1} (g_{ij-1} A^i g^{ij} + g^{ij-1} dg^{ij} + t^{Lie}(\eta^{ij})) g^{jk} + g^{jk-1} dg^{jk}
\]

\[
+ t^{Lie}(\eta^{jk})) g^{ik-1} - A^i - dg_{ik} g^{ik-1}
\]

After some algebra we find

\[
g_{ij} g^{jk} g^{ik-1} g_{ik} t^{Lie}(\eta^{ik}) g^{jk-1} g_{ik} g^{ik-1} g_{ij-1}
\]

\[
= A^i - g_{ij} g^{jk} g^{ik-1} A^i g^{jk} g^{ik-1} g_{ij-1} + d(g_{ij} g^{ik} g^{ik-1}) g^{ik} g^{ik-1} g_{ij-1}
\]

\[
+ g_{ij} t^{Lie}(\eta^{ij}) g^{ij-1} + g_{ij} g^{jk} t^{Lie}(\eta^{jk}) g^{jk-1} g_{ij-1}
\]

Finally by using the relation $g^{ik} g^{ik-1} g_{ij-1} = t(h^{ijk})$ we prove the property modulo an ignored element of $\text{ker} t^{Lie}$ without significance. \(\square\)

The local data defining a 2-bundle with a 2-connection are summarized in table 1.

5 Horizontal lifts

5.1 Pseudosurfaces

The construction scheme of a 2-bundle over an affine 2-space shows that the natural objects which can be lift in the bundle are not the surfaces but geometric entities related to the categorical structure.
Definition 17 (Pseudosurfaces). Let $\mathcal{M}$ be an affine 2-space. A pseudosurface is a smooth map $\gamma : [0,1] \to \text{Morph}(\mathcal{M})$ such that $\gamma(u)$ is constant near $u = 0$ and near $u = 1$.

By definition, all pseudosurface on a spherical affine 2-space is reduced to a path-identity in $\mathcal{M}$ ($u \mapsto \text{id}_{\gamma(u)}$).

The path on $\mathcal{M} = \text{Obj}(\mathcal{M})$ defined by $u \mapsto s(\gamma(u))$ is called the source-boundary of the pseudosurface $\gamma$, and the path $u \mapsto t(\gamma(u))$ is called the target-boundary. Let $\{[0,1] \ni u \mapsto x_i(u) \in M\}_{i=1,...,n}$ be the minimal set of smooth paths such that $\gamma(u) = x_n(u)\ldots x_1(u)$. $\text{Skel}_\gamma(u) = (x_n(u),...,x_1(u))$ is called the skeleton of the pseudosurface. We note that a skeleton can have junctions in the case where $x_i(u) = x_{i+1}(u)$ for $u \leq u_*$ (for example). A pseudosurface which has a skeleton reduced to its boundary is said elementary. By definition, all pseudosurface on an euclidean affine 2-space is elementary. It is interesting to point out some special cases of pseudosurfaces:

- A pseudosurface is said impervious if its boundary is closed : $\gamma(0) = \text{id}_{s(\gamma(0))}$ and $\gamma(1) = \text{id}_{s(\gamma(1))}$. An impervious pseudosurface is well delimited.
- A pseudosurface is said cyclic if it is impervious and if $\gamma(0) = \gamma(1)$.
- A pseudosurface is said pinched if $\forall u \in [0,1]$, $s(\gamma(u)) = s(\gamma(0))$ or/and $t(\gamma(u)) = t(\gamma(0))$.

Definition 18 (Composition laws of pseudosurfaces). Let $\gamma_1$ and $\gamma_2$ be two pseudosurfaces such that (for two parametrizations $u \mapsto \gamma_1(u)$ and $u \mapsto \gamma_2(u)$) $\text{Skel}_{\gamma_1}(1) = \text{Skel}_{\gamma_2}(0)$. The horizontal composition of these two pseudosurfaces is the pseudosurface $\gamma_1 \ast \gamma_2$ defined by the skeleton

$$\forall u \in [0,1], \quad \text{Skel}_{\gamma_1 \ast \gamma_2}(u) = \begin{cases} \text{Skel}_{\gamma_1}(2u) & \text{if } u \in [0,\frac{1}{2}] \\ \text{Skel}_{\gamma_2}(2u-1) & \text{if } u \in [\frac{1}{2},1] \end{cases}$$

Let $\gamma_1$ and $\gamma_2$ be two pseudosurfaces such that $\forall u$, $s(\gamma_1(u)) = t(\gamma_2(u))$. The vertical composition of the two pseudosurfaces is the pseudosurface $(\gamma_1 \circ \gamma_2)(u) = \gamma_1(u) \circ \gamma_2(u)$ (in the r.h.s. $\circ$ denotes the arrows composition of $\text{Morph}(\mathcal{M})$).

The pseudosurfaces define a category $\mathcal{PS}(\mathcal{M})$ with the smooth paths of $\mathcal{M}$ as objects, the pseudosurfaces as arrows and the vertical composition as arrows composition.
### 5.2 Horizontal lifts of pseudosurfaces

**Definition 19** (Horizontal lifts of an elementary pseudosurface). Let $\mathcal{P}$ be a 2-bundle over an affine 2-space $\mathcal{M}$ endowed with a 2-connection. Let $\gamma : [0, 1] \to \text{Morph}(\mathcal{M})$ be an elementary pseudosurface. A map $\tilde{\gamma} : [0, 1] \to \text{Morph}(\mathcal{P})$ is said to be a horizontal lift of $\gamma$ if $\forall u \in [0, 1]$, $\pi(\tilde{\gamma}(u)) = \gamma(u)$ and if $\gamma(u) \in \text{Morph}(\mathcal{U}^i)$ we have $X^i_\gamma(u) \in H_{\tilde{\gamma}(u)}Q^i$, $X^i_{\gamma(\tilde{\gamma})}(u) \in H_{\gamma(\tilde{\gamma}(u))}P^i$ and $X^i_{t(\tilde{\gamma})}(u) \in H_{t(\tilde{\gamma}(u))}P^i$ where $X^i_\gamma$ is the tangent vector of $\tilde{\gamma}$ viewed as a path in $Q^i$ and $X^i_{s(\tilde{\gamma})}, X^i_{t(\tilde{\gamma})} \in TP^i$ are the tangent vectors of $s(\tilde{\gamma})$ and $t(\tilde{\gamma})$ viewed as paths in $P^i$.

Let $\sigma^i \in \text{Funct}(\mathcal{U}^i, \mathcal{P})$ be the trivializing local section: $\sigma^i(x) = \phi^i(x, e_G) = \hat{\sigma}^i_p(x)$ and $\sigma^i(\tilde{\gamma}(x)) = \phi^i(\tilde{\gamma}(x), e_H, e_G) = \tilde{\sigma}^i_Q(y, x)$. Let $\gamma$ be an elementary pseudosurface completely included in $\mathcal{U}^i$ ($\forall u \in [0, 1]$, $\gamma(u) \in \varphi(U^i \times U^i_{\mathcal{R}})$). The horizontal lift of $\gamma$ passing through $\sigma^i(\gamma(0))$ is

$$
\tilde{\gamma}^i(u) = R(\mathbb{P}_\gamma e^{-\int_{(y(u), x(u))} \eta^i(y, x)})\sigma^i(\gamma(u)) = \phi^i(\gamma(u), \mathbb{P}_\gamma e^{-\int_{(y(0), x(0))} \eta^i(y, x)})
$$

$\mathbb{P}_\gamma e^{-\int_{(y(0), x(0))} \eta^i(y, x)} \in H \rtimes G$ is path-ordered exponential along the path $u \mapsto (t(\gamma(u)), s(\gamma(u))) \in U^i \times U^i_{\mathcal{R}}$ (in order to simplify the notation we have denoted $s(\gamma(u))$ by $x(u)$ and $t(\gamma(u))$ by $y(u)$). By definition of the path-ordered exponential, $\mathbb{P}_\gamma e^{-\int_{(y(0), x(0))} \eta^i(y, x)}$ is solution of

$$
\frac{d\mathbb{P}_\gamma e^{-\int_{(y(0), x(0))} \eta^i(y, x)}}{du} = -\eta^i(y(u), x(u))\mathbb{P}_\gamma e^{-\int_{(y(0), x(0))} \eta^i(y, x)}
$$

We find this result by applying the horizontal lift formula in the local $H \rtimes G$-bundle $Q^i$. The horizontalities in $P^i$ are ensured by the relations between $HQ^i$ and $HP^i$ of the definition of a 2-connection. The horizontal lift of $\gamma$ passing through $q \in \text{Morph}(\mathcal{P})$ with $\pi(q) = \gamma(0)$ is then $\tilde{\gamma}^i_q(u) = R(h, g)\tilde{\gamma}^i(u)$ where $(h, g) \in H \rtimes G$ is such that $R(h, g)\sigma^i(\gamma(0)) = q$.

$\mathbb{P}_\gamma e^{-\int_{(y(0), x(0))} \eta^i(y, x)}$ is an element of $H \rtimes G$ represented in the universal enveloping algebra of $\mathfrak{h} \in \mathfrak{g}$. It is more interesting to have an expression of the horizontal lift as a couple $(h(u), g(u))$ with $h(u) \in H$ and $g(u) \in G$. A such expression is simple in the case where $H$ is the center of $G$ ($1 \to H \to G \to G/H \to 1$ is then a central extension of groups, $t$ is just the canonical injection of $H$ in $G$ and $\alpha$ is just the conjugation $\alpha_g(h) = ghg^{-1}$). Since
\( \eta^i(y, x) = \eta^i(y, x) + A^i(x) \) with \( A^i(x) \in g \) and \( \eta^i(y, x) \in \mathfrak{h} \) we have

\[
(86) \quad \mathbb{P}_\gamma e^{-\int_{[y(0), x(0)]}^y \eta^i(y, x)} = \left( e^{-\int_{[y(0), x(0)]}^y \eta^i(y, x)} \mathbb{P}_{s(\gamma)} e^{-\int_{x(0)}^{x} A^i(x)} \right)
\]

where \( \mathbb{P}_{s(\gamma)} e^{-\int_{x(0)}^{x} A^i(x)} \in G \) is the path-ordered exponential along the path 
\( u \mapsto s(\gamma(u)) = x(u) \in \mathcal{U}^i \). \( e^{-\int_{[y(0), x(0)]}^y \eta^i(y, x)} \in H \) is written without path-ordering since \( H \) is abelian if it is the center of \( G \) (the expression is then an usual exponential). Since we consider a pseudosurface, it is interesting to view \( e^{-\int_{[y(0), x(0)]}^y \eta^i(y, x)} \) as a surface element. For this we suppose that \( \forall u \in [0, 1], x(1) \) and \( y(u) \) are linkable and \( x(u) \) and \( y(0) \) are linkable. Let \( C^2_\gamma \) be the closed path in \( U^i \times U^i \) defined by \( [0, 1] \ni u \mapsto (y(u), x(u)) \) for its first part, \( [0, 1] \ni u \mapsto (y(1 - u), x(1)) \) for its second part, and \( [0, 1] \ni u \mapsto (y(0), x(1 - u)) \) for its last part. Let \( S^2_\gamma \) be a surface in \( U^i \times U^i \) having \( C^2_\gamma \) as boundary \( \partial S^2_\gamma = C^2_\gamma \). We call \( S^2_\gamma \) a surface of the second kind supported by the pseudosurface \( \gamma \). We can decompose \( \eta^i \) as the following

\[
(87) \quad \eta^i(y, x) = \eta^i_{x\mu}(y, x) dx^\mu + \eta^i_{y\mu}(y, x) dy^\mu
\]

where \( \eta^i_{x\mu} \in \Omega^1_U \hat{\eta}^i_{x\mu}(y, x) \) and \( \eta^i_{y\mu} \in \Omega^1_U \hat{\eta}^i_{y\mu}(y, x) \). By considering the three parts of \( C^2_\gamma \) we have

\[
(88) \quad \oint_{C^2_\gamma} \eta^i = \oint_{S^2_\gamma} d(y) \eta^i = \oint_{S^2_\gamma} B^i_{n s}, \text{ and then}\n\]

\[
(89) \quad \oint_{(y(1), x(1))} \eta^i(y, x) = \oint_{S^2_\gamma} B^i_{n s}(y, x) + \int_{y(0)}^{y(1)} \eta^i_{y}(y, x) + \int_{x(0)}^{x(1)} \eta^i_{x}(y, x)
\]

Finally the horizontal lift of \( \gamma \) is associated with

\[
(90) \quad \mathbb{P}_\gamma e^{-\int_{[y(0), x(0)]}^y \eta^i(y, x)} = \left( e^{-\int_{[y(0), x(0)]}^y \eta^i_{y}(y, x)} e^{-\int_{[y(0), x(0)]}^y \eta^i_{x}(y, x)} \mathbb{P}_{s(\gamma)} e^{-\int_{x(0)}^{x} A^i(x)} \right)
\]

This last expression makes appear explicitly a surface \( S^2_\gamma \) supported by the pseudosurface and the boundaries \( s(\gamma), t(\gamma) \) of the pseudosurface. We suppose now that \( \gamma \) is impervious (and still that \( \forall u \in [0, 1], y(u) \) and \( x(1) = y(1) \) are linkable, and \( x(u) \) and \( x(0) = y(0) \) are linkable). Let \( C^2_\gamma \) be the closed path in \( U^i \) defined by \( [0, 1] \ni u \mapsto y(u) \) \( (t(\gamma)) \) for its first part and \( [0, 1] \ni u \mapsto x(1 - u) (s(\gamma)^{-1}) \) for its second part. By the property of \( \eta^i \) with
t^{\text{Lie}} we have $t^{\text{Lie}}(\eta^i_s(y,x)) = -A^i(x)$ and $t^{\text{Lie}}(\eta^i_s(y,x)) = A^i(y)$, and then

$$t \left( e^{-\int_{s(\gamma)} \eta^i(y,0,0) - \int_{t(\gamma)} \eta^i(y,x(1))} \right) = P_{\gamma} e^{-f_{\gamma(y)}} A^i$$

By invoking a non-abelian Stokes theorem \cite{29} we can write $P_{\gamma} e^{-f_{\gamma(y)}} A^i$ as an ordered exponential of $F^i + t^{\text{Lie}}(B_{sph}^i)$ along $S^1_\gamma$ (a surface in $U^i$ having $C^1_\gamma$ as boundary). But by construction $P_{\gamma} e^{-f_{\gamma(y)}} A^i \in t(H)$ and then

$$\varphi \left( P_{\gamma} e^{-f_{\gamma(y)}} A^i \right) = e_{G/H}. \text{ We can then choose } F^i = 0 \text{ on } S^1_\gamma. \text{ We have then}$$

$$t \left( e^{-\int_{s(\gamma)} \eta^i(y,0,0) - \int_{t(\gamma)} \eta^i(y,x(1))} \right) = P_{\gamma} e^{-f_{\gamma(y)}} A^i$$

We have a such drastic reduction because we have supposed that $\forall u \in [0,1]$, $y(u)$ and $x(1) = y(1)$ are linkable and $x(u)$ and $x(0) = y(0)$ are linkable. If this is not the case, $P_{\gamma} e^{-f_{\gamma(y)}} A^i \notin t(H)$ ($\eta^i(y,0,1)$ and $\eta^i(y(0),x)$ are not defined). We call $S^1_\gamma$ a surface of the first kind supported by the pseudosurface $\gamma$. Finally we have

$$P_{\gamma} e^{-\int_{[y(0),x(0)]} \eta^i(y,x)} = \left( e^{-\int_{S^2_\gamma} B_{sph}^i(y,x) - \int_{S^1_\gamma} B_{sph}^i(x)} P_{\gamma} e^{-\int_{s(\gamma)} A^i(x)} \right)$$

For the general case (where $H$ is not the center of $G$ and is not necessary abelian) the situation is more complicated. We can separate the parts of $H$ and $G$ by using the intermediate representation theorem \cite{30}:

$$P_{\gamma} e^{-\int_{[y(0),x(0)]} \eta^i(y,x)} = \left( P_{\gamma} e^{-\int_{[y(0),x(0)]} \eta^i(y,x)} P_{s(\gamma)} e^{-\int_{x(0)} A^i(x)} \right)$$

where

$$\tilde{\eta}^i(y(u),x(u)) = \alpha P_{s(y)} e^{-\int_{x(0)} A^i(\eta^i(x(u),y(u)))}$$

To make appear surface integrations for the element of $H$, we need the use of very complicated expressions issued from the non-abelian Stokes theorem \cite{29}. To avoid this difficulty we will consider an infinitesimal elementary pseudosurface. To this, we need some results of simplicial geometry \cite{31}, \cite{32}, \cite{33}. Let $\{K_n\}_{n \in \mathbb{N}}$ be a family of smooth triangulations of $U^i \times U^j_R$ (a triangulation is a triangular network covering $U^i \times U^j_R$, a triangular cell of this network is called a simplex), such that $\bigcup_{n \in \mathbb{N}} K_n = U^i \times U^j_R$. Let $(C^{\infty}(K_n, h), +, \cup, \delta)$ be the Čech differential algebra defined by:
• $C^p(K_n, \mathfrak{h})$ is the algebra of antisymmetric maps form $(K_n)^p$ to $\mathfrak{h}$ called the $p$-cochains.
• $\delta : C^p(K_n, \mathfrak{h}) \to C^{p+1}(K_n, \mathfrak{h})$ the cobord operator is $\forall \omega \in C^p(K_n, \mathfrak{h})$

$$ (\delta \omega)_{u_0...u_{p+1}} = \sum_{j=0}^{p+1} (-1)^j \omega_{u_0...\hat{u}_j...u_{p+1}} $$

$u_i \in K_n$ and $\hat{u}_j$ signifies “deprive of $u_j$”.
• $\cup : C^p(K_n, \mathfrak{h}) \times C^q(K_n, \mathfrak{h}) \to C^{p+q}(K_n, \mathfrak{h})$ the cup-product is $\forall \omega \in C^p(K_n, \mathfrak{h})$, $\forall \eta \in C^q(K_n, \mathfrak{h})$

$$ (\omega \cup \eta)_{u_0...u_{p+q}} = \frac{1}{(p+1)!(q+1)!} \sum_{\sigma \in S_{p+q+1}} (-1)^\sigma [\omega_{u_{\sigma(0)}...u_{\sigma(p)}}, \eta_{u_{\sigma(p+1)}...u_{\sigma(p+q)}}] $$

$S_{p+q+1}$ being the group of permutations and $(-1)^\sigma$ being the signature of the permutation $\sigma$.

At the inductive limit of the refinement $n \to +\infty$, the Čech differential algebra is isomorphic to the de Rham differential algebra $(\Omega^\ast(U^i \times U^j_\mathcal{R}, \mathfrak{h}), +, \wedge, d_{(2)})$. The isomorphism is induced by the de Rham map $R_n : \Omega^\ast(U^i \times U^j_\mathcal{R}, \mathfrak{h}) \to C^\ast(K_n, \mathfrak{h})$, $\forall \omega \in \Omega^p(U^i \times U^j_\mathcal{R}, \mathfrak{h})$

$$ R_n(\omega)_{u_0...u_p} = \int_{\{u_0...u_p\}} \omega $$

where $\{u_0...u_p\}$ is a $p$ dimensional submanifold of $U^i \times U^j_\mathcal{R}$ forming a simplex with $u_0, ..., u_p$ as vertices ($\{u_0u_1\}$ is an edge, $\{u_0u_1u_2\}$ is a triangular cell, $\{u_0u_1u_2u_3\}$ is a tetrahedron, etc). The reciprocal map is the Whitney map $W_n : C^\ast(K_n, \mathfrak{h}) \to \Omega^\ast(U^i \times U^j_\mathcal{R}, \mathfrak{h})$ (see 31 32 33). It is interesting to note that $\forall \omega \in \Omega^p(U^i \times U^j_\mathcal{R}, \mathfrak{h})$

$$ (\delta R_n(\omega))_{u_0...u_{p+1}} = \int_{\{u_0...u_{p+1}\}} d_{(2)}\omega \iff \delta R_n(\omega) = R_n(d_{(2)}\omega) $$

and $\forall \omega \in \Omega^p(U^i \times U^j_\mathcal{R})$, $\forall \eta \in \Omega^q(U^i \times U^j_\mathcal{R})$

$$ \lim_{n \to +\infty} W_n(R_n(\omega) \cup R_n(\eta)) = \omega \wedge \eta $$

(the limit being defined with the topology of a $L^2$-norm see 31 32 33). Let $\epsilon_n$ be “the edge length” of $K_n$ (i.e. $\forall \eta \in \Omega^1(U^i \times U^j_\mathcal{R})$, $R_n(\eta)_{u_0u_1} = \mathcal{O}(\epsilon_n)$ with $\lim_{n \to +\infty} \epsilon_n = 0$). It is interesting to note, that the Cartan structure equation $\beta = d\alpha + \alpha \wedge \alpha$ (with $\alpha \in \Omega^1(U^i \times U^j_\mathcal{R}, \mathfrak{h})$) takes the form

$$ e^{R_n(\alpha)_{u_1u_2}} e^{-R_n(\alpha)_{u_0u_2}} e^{R_n(\alpha)_{u_0u_1}} = e^{R_n(\beta)_{u_0u_1u_2}} + \mathcal{O}(\epsilon_n^3) $$
by using the Baker-Campbell-Hausdorff formula \((34)\) at the second order $e^a e^b = e^{a + b + \frac{1}{2}[a, b] + O(\epsilon^3)}$ for $a, b \in \mathfrak{g}$ and $a, b = O(\epsilon_n)$.

Let $\gamma : [0, 1] \to \text{Morph}(\mathcal{M})$ be an elementary pseudosurface such that $(y(0), x(0)), (y(1), x(1)), (y(0), x(1)) \in K_n$ with $n$ large and such that $\forall u \in [0, 1]$, $x(1)$ and $y(u)$ are linkable and $x(u)$ and $y(0)$ are linkable.

Let $C^2_\gamma$ be the closed path in $U^i \times U^i$ defined by $[0, 1] \ni u \mapsto (y(u), x(u))$ for its first part, $[0, 1] \ni u \mapsto (y(1 - u), x(1))$ for its second part, and $[0, 1] \ni u \mapsto (y(0), x(1 - u))$ for its last part. For sake of simplicity we denote $u_0 = (y(0), x(0)), u_1 = (y(1), x(1))$ and $u_2 = (y(0), x(1))$. We can assimilate $S^2_x$ to the simplex (the triangular cell) $<u_0 u_1 u_2>$ of $K_n$. Using the Baker-Campbell-Hausdorff formula at the second order we have then

$$
e^{R_n(y')} u_1 u_2 e^{-R_n(y')} u_0 u_2 e^{-R_n(A')} u_0 u_2 e^{R_n(y')} u_0 u_1
= \exp \left( \delta R_n(y') u_0 u_1 u_2 + R_n(y') \cup R_n(y') u_0 u_1 u_2
+ R_n(y') \cup R_n(A') u_0 u_1 u_2 + R_n(y') \cup R_n(y') u_0 u_1 u_2 + O(\epsilon_n^3) \right)
$$

(102)

Finally by writting that $\mathbb{P}_\gamma e^{-\int_{y(0), x(0)}^{y(1), x(1)} \delta y', x} \simeq e^{R_n(y')} u_0 u_1$, the horizontal lift for an infinitesimal elementary pseudosurface $\gamma$ is

$$
\mathbb{P}_\gamma e^{-\int_{y(0), x(0)}^{y(1), x(1)} \delta y', x} \simeq \left( e^{- \int_S S^2 \delta H_\gamma(y, x) - \int_{s(\gamma)} \eta^1(y, x)} e^{\int_{s(\gamma)} \eta^1(y, x)}, e^{\int_{s(\gamma)} A^i(x)} \right)
$$

(103)

Moreover, if $\gamma$ is impervious we have

$$
\mathbb{P}_\gamma e^{-\int_{y(0), x(0)}^{y(1), x(1)} \delta y', x} \simeq \left( e^{- \int_S S^2 \delta H_\gamma(y, x) - \int_{s(\gamma)} \eta^1(y, x)} e^{\int_{s(\gamma)} \eta^1(y, x)} \right)
$$

(104)

Let $H^\ell : \text{Morph}(\mathcal{U}^i)_{[0, 1]} \to H \rtimes G$ be the map which associates to an elementary pseudosurface the group element associated with its horizontal lift: $H^\ell(\gamma) = \mathbb{P}_\gamma e^{-\int_{y(0), x(0)}^{y(1), x(1)} \delta y', x}$. We extend $H^\ell$ as a functor from $\mathcal{P}(\mathcal{U}^i)$ to $G$ transforming the horizontal composition to the horizontal composition and the vertical composition to the vertical composition:

$$
H^\ell(\gamma_1 \ast \gamma_2) = H^\ell(\gamma_1) \cdot H^\ell(\gamma_2)
$$

(105)

$$
H^\ell(\gamma_1 \circ \gamma_2) = H^\ell(\gamma_1) \circ H^\ell(\gamma_2)
$$

(106)

“$\ast$” denotes the group law of $H \rtimes G$. This functor permits to define the horizontal lift of any pseudosurface $\gamma$ of $U^i$. Let

$$
\gamma = (\gamma_1 \circ \ldots \circ \gamma_n) \ast \ldots \ast (\gamma_{p1} \circ \ldots \circ \gamma_{pm})
$$

(107)
be a decomposition where each $\gamma_{ij}$ is an infinitesimal elementary pseudosurface. The horizontal lift of $\gamma$ is then

$$H^\ell(\gamma) = (H^\ell(\gamma_{11}) \circ \ldots \circ H^\ell(\gamma_{1n}) \ast \ldots \ast (H^\ell(\gamma_{p1}) \circ \ldots \circ H^\ell(\gamma_{pn}))$$

This decomposition is well defined because of the exchange laws: $\forall \gamma_{11}, \gamma_{12}, \gamma_{21}, \gamma_{22} \in \mathcal{PS}(U^i)$ with $\text{Skel}_{\gamma_{11}}(1) = \text{Skel}_{\gamma_{21}}(0)$, $\text{Skel}_{\gamma_{12}}(1) = \text{Skel}_{\gamma_{22}}(0)$, $s(\gamma_{11}(u)) = t(\gamma_{12}(u))$ and $s(\gamma_{21}(u)) = t(\gamma_{22}(u))$

$$\begin{equation}
(\gamma_{11} \circ \gamma_{12}) \ast (\gamma_{21} \circ \gamma_{22}) = (\gamma_{11} \ast \gamma_{21}) \circ (\gamma_{12} \ast \gamma_{22})
\end{equation}$$

and $\forall h_{11}, h_{12}, h_{22}, h_{21} \in H$, $\forall g_{12}, g_{22} \in G$

$$((h_{11}, t(h_{12})g_{12}) \circ (h_{12}, g_{22})) \ast ((h_{21}, t(h_{22})g_{22}) \circ (h_{22}, g_{22}))$$

$$= ((h_{11}, t(h_{12})g_{12}) \cdot (h_{21}, t(h_{22})g_{22})) \circ ((h_{12}, g_{12}) \cdot (h_{22}, g_{22}))$$

Now, we need to define the horizontal lifts of pseudosurfaces extending on several charts. Well defined horizontal lifts of paths and surfaces crossing several charts have been studied by Alvarez in [35]. Unfortunately, these results cannot be used directly in the present context.

Let $\gamma^i$ be an infinitesimal elementary pseudosurface of $U^i$ and $\gamma^j$ be an infinitesimal elementary pseudosurface of $U^j$ such that $\gamma^i(1) = \gamma^j(0)$. Following the usual horizontal lift formula for a path (with $\eta$) we extend $H^\ell$ as follows

$$H^\ell(\gamma^i \ast \gamma^j) = H^\ell(\gamma^i) \cdot (h_{ij}(y_*, x_*), g_{ij}(x_*)) \cdot H^\ell(\gamma^j)$$

where $x_* = s(\gamma^i(1)) = s(\gamma^j(0)) \in U^i \cap U^j$ and $y_* = t(\gamma^i(1)) = t(\gamma^j(0)) \in U^i \cap U^j$. We can note that this formula depends on the point $(y_*, x_*) \in (U^i \cap U^j)^2_R$. The formula is different for two over pseudosurfaces such that $\gamma^i \ast \gamma^j = \gamma^j \ast \gamma^i$ but with $(y_*, x_*) \neq (y_*, x_*)$. This is due to the fact that $\eta^j = q^{ij-1} \eta^j q_{ij} + q^{ij-1} d_2 \gamma^j$. Nevertheless, if the pseudosurfaces are infinitesimal, we can think that the defect $\mathbb{P}_e^{(\eta^j)}((t^{\text{Lie}}(\eta^j(x_*)) + \eta^j(y_* - \eta^j(x_*)))$ is negligible.

Let $\gamma^i$ be an infinitesimal elementary pseudosurface of $U^i$ and $\gamma^j$ be an infinitesimal elementary pseudosurface of $U^j$ such that $s(\gamma^j) = t(\gamma^i) = C_* \subset U^i \cap U^j$. The vertical composition of $H^\ell(\gamma^i)$ with $H^\ell(\gamma^j)$ cannot directly be performed since

$$t(H^\ell(\gamma^j)) = \mathbb{P}_e^{-f_c, A^j} \neq \mathbb{P}_e^{-f_c, A^j} = s(H^\ell(\gamma^j))$$

Since $A^j = g^{ij-1} A^i g^{ij} + g^{ij-1} d g^{ij} + t^\text{Lie}(\eta^j)$ we have

$$\begin{equation}
\mathbb{P}_e^{-f_c, A^j} = \mathbb{P}_e^{-f_c, A^j} \cdot (t^{\text{Lie}}(\alpha_{\eta^j}(\eta^j))) g_{ij}(x_*(0))
\end{equation}$$

with $s(\gamma^j(u)) = t(\gamma^i(u)) = x_*(u)$ ($\forall u \in [0, 1]$). Since we have

$$t \left( \mathbb{P}_e^{-f_c, A^j} \cdot (t^{\text{Lie}}(\alpha_{\eta^j}(\eta^j))) + O(c^2) \right) = \mathbb{P}_e^{-f_c, A^j} \cdot (t^{\text{Lie}}(\alpha_{\eta^j}(\eta^j))) + O(c^2)$$

$$= \mathbb{P}_e^{-f_c, A^j} \cdot (t^{\text{Lie}}(\alpha_{\eta^j}(\eta^j))) + O(c^2)$$
we set
\[
\mathcal{H}_\ell (\gamma^j \circ \gamma^i) = \mathcal{H}_\ell (\gamma^j) \circ \\
((e_{\mathcal{H}}, g^{ij}(x_*(1))^{-1}) \cdot \\
\left(\left(\mathbb{P}_e e^{-J_e \alpha_{g_{ij}(\eta^{ij})}} \mathbb{P}_e e^{-J_e A^i} \circ \mathcal{H}_\ell (\gamma^i)\right) \cdot \\
(e_{\mathcal{H}}, g^{ij}(x_*(0)))\right)
\]
(115)

Let \(\gamma^i\) be an infinitesimal elementary pseudosurface of \(U^i\), \(\gamma^j\) be an infinitesimal elementary pseudosurface of \(U^j\) and \(\gamma^k\) be an infinitesimal elementary pseudosurface of \(U^k\), such that \(\gamma^i(1) = t(\gamma^k(0))\) and \(s(\gamma^i(1)) = s(\gamma^j(0)) = t(\gamma^j(0))\) = \(x_* \in U^i \cap U^j \cap U^k\). To be coherent with the branching point \(x_*\) which is on the triple overlap, we set
\[
\mathcal{H}_\ell \left(\gamma^i \ast (\gamma^k \circ \gamma^j)\right) = \mathcal{H}_\ell (\gamma^i) \cdot (h^{ik}(y_*, x_*) h^{jk}(x_*) g^{ij}(x_*) g^{jk}(x_*)) \cdot \mathcal{H}_\ell (\gamma^k \circ \gamma^j)
\]
(116)
where \(y_* = t(\gamma^i(1)) = t(\gamma^k(0))\). Moreover we set similar formulae for the other situations with a branching point on a triple overlap.

With all these definitions, \(\mathcal{H}_\ell\) can be extended as a functor of \(\mathcal{PS}(\mathcal{M})\) to \(\mathcal{G}\). By decomposing any pseudosurface into infinitesimal elementary pseudosurfaces, we can define any horizontal lift.

6 Example: The Bloch wave operators in quantum dynamics

6.1 The Bloch wave operators

The studies of quantum dynamical systems with “large Hilbert space” (i.e. quantum systems where a large number of independent states are involved in the dynamics) are generally difficult for the theoretical viewpoint as for the numerical viewpoint. Methods involving active spaces, effective hamiltonians and wave operators are good tools to solve this problem (see [36], [37], [38]).

Let \(G_m(\mathcal{H}) = \{P \in \mathcal{B}(\mathcal{H}), P^2 = P, P^\dagger = P, \text{tr} P = m\}\) be the space of rank \(m\) orthogonal projectors of the separable Hilbert space \(\mathcal{H}\). \(\mathcal{B}(\mathcal{H})\) denotes the set of bounded operators of \(\mathcal{H}\). If \(\mathcal{H}\) is finite dimensional, i.e. \(\mathcal{H} \simeq \mathbb{C}^n\), \(G_m(\mathbb{C}^n)\) is a complex manifold called a complex grassmanian [39]. This manifold is endowed with a Kählerian structure (see [40]), and particularly
with a distance (called the Fubini-Study distance) defined by

\[ \forall P_1, P_2 \in G_m(\mathbb{C}^n), \quad \text{dist}_{FS}(P_1, P_2) = \arccos |\det Z_1^\dagger Z_2|^2 \]

where \( Z_1, Z_2 \in \mathfrak{M}_{n \times m}(\mathbb{C}) \) are the matrices of two arbitrary orthonormal basis of \( \text{Ran} \, P_1 \) and \( \text{Ran} \, P_2 \) expressed in an orthonormal basis of \( \mathbb{C}^n \). We can note that \( 0 \leq \text{dist}_{FS}(P_1, P_2) \leq \frac{\pi}{2} \). The Fubini-Study distance measures the “quantum compatibility” between the two subspaces \( \text{Ran} \, P_1 \) and \( \text{Ran} \, P_2 \) in the sense where \( \text{dist}_{FS}(P_1, P_2) = \frac{\pi}{2} \) if and only if \( \text{Ran} \, P_1^\perp \cap \text{Ran} \, P_2 \neq \{0\} \) or \( \text{Ran} \, P_1 \cap \text{Ran} \, P_2^\perp \neq \{0\} \), i.e. if there exists a state of \( \text{Ran} \, P_1 \) for which the probability of obtaining the same measures as that with a system in a state of \( \text{Ran} \, P_2 \) is zero (see [41]).

For an infinite dimensional Hilbert space, it is possible to define a manifold \( G_m(\mathcal{H}) \) endowed with a Kählerian structure by using the inductive limit technique (see [39]).

Let \( P_0, P \in G_m(\mathcal{H}) \) be such that \( \text{dist}_{FS}(P_0, P) < \frac{\pi}{2} \). We call wave operator associated with \( \text{Ran} \, P_0 \) and \( \text{Ran} \, P \) the operator \( \Omega \in \mathcal{B}(\mathcal{H}) \) defined by

\[ \Omega = P(P_0 PP_0)^{-1} \]

where \( (P_0 PP_0)^{-1} = P_0(P_0 PP_0)^{-1}P_0 \) is the inverse of \( P \) within \( \text{Ran} \, P_0 \) (it exists only if \( P \) is not too far from \( P_0 \), i.e. \( \text{dist}_{FS}(P, P_0) < \frac{\pi}{2} \)). Usually wave operators are used to solve eigenequation [36]. In that case, we solve an effective eigenequation \( H^{\text{eff}} \psi_0 = \lambda \psi_0 \) where \( H^{\text{eff}} = P_0 H \Omega \in \mathcal{L}(\text{Ran} \, P_0) \) is the effective Hamiltonian within \( \text{Ran} \, P_0 \) (\( H \in \mathcal{B}(\mathcal{H}) \) is the true self-adjoint Hamiltonian). We recover the true eigenvector associated with \( \lambda \), \( H \psi = \lambda \psi \), by \( \psi = \Omega \psi_0 \in \text{Ran} \, P \) (\( \psi_0 = P_0 \psi \)). \( \Omega \) is called a Bloch wave operator and is obtained by solving the Bloch equation

\[ [H, \Omega] \Omega = 0 \]

Since \( \Omega^2 = \Omega \), a Bloch wave operator can be viewed as a non-linear generalization of an eigenprojector (an eigenprojector satisfies \( [H, P] = 0 \) with \( P^2 = P \)). Physically, a Bloch wave operator compares the approximate eigenstates within \( \text{Ran} \, P_0 \) (which is called the active subspace) with the associated true eigenstates.

We define a weak left inverse of a wave operator: if \( \Omega = P(P_0 PP_0)^{-1} \) then \( \Omega^{-1} = P_0 P \) satisfies \( \Omega^{-1} \Omega = P_0 \).

In a same manner, in order to compare an approximate quantum dynamics within an active space \( \text{Ran} \, P_0 \) with the true dynamics, we can introduce the time-dependent wave operator [37]:

\[ \Omega(t) = P(t)(P_0 P(t)P_0)^{-1} \]
where \((P_0 P(t) P_0)^{-1}\) is still the inverse within \(\text{Ran} P_0\), and where \(t \mapsto P(t) \in G_m(\mathcal{H})\) is the solution of the Schrödinger-von Neumann equation:

\[
\dot{P}(t) = [H(t), P(t)] \quad P(0) = P_0
\]

\(H(t) \in \mathcal{B}(\mathcal{H})\) is the self-adjoint time-dependent Hamiltonian. We solve then the following effective Schrödinger equation within \(\text{Ran} P_0\): \(i \hbar \partial_t \psi_0(t) = H^{\text{eff}}(t) \psi_0(t)\), where \(H^{\text{eff}}(t) = P_0 H(t) \Omega(t) \in \mathcal{L}(\text{Ran} P_0)\) is the effective Hamiltonian. We recover the true wave function, which is the solution of \(i \hbar \partial_t \psi(t) = H(t) \psi(t)\), by \(\psi(t) = \Omega(t) \psi_0(t)\) (\(P_0 \psi(t) = \psi_0(t)\)). The time-depend wave operator can be used only if the dynamics does not escape too far from the initial subspace, i.e. \(\forall t, \text{dist}_{\mathcal{F}_S}(P(t), P_0) < \frac{\pi}{2}\). Since \(P(t) = U(t, 0) P_0 U(t, 0)^\dagger\), where \(U(t, 0) \in \mathcal{U}(\mathcal{H})\) is the evolution operator \((\hbar U(t, 0) = H(t) U(t, 0), U(0, 0) = 1; \mathcal{U}(\mathcal{H})\) denotes the set of unitary operators of \(\mathcal{H}\)), we can also write

\[
\Omega(t) = U(t, 0)(P_0 U(t, 0) P_0)^{-1}
\]

By using this expression, it is not difficult to prove that the time-dependent wave operator satisfies

\[
i \hbar \dot{\Omega}(t) = [H(t), \Omega(t)] \Omega(t) \quad \Omega(0) = P_0
\]

We can also introduce the generalized time-dependent wave operator:

\[
\Omega(t) = P(t)(P_0(t) P(t) P_0(t))^{-1}
\]

where \(t \mapsto P(t) \in G_m(\mathcal{H})\) is the solution of the Schrödinger-von Neumann equation and where \(t \mapsto P_0(t) \in G_m(\mathcal{H})\) is a \(\mathcal{C}^2\) instantaneous eigenprojector: \(\forall t, [H(t), P_0(t)] = 0\). This wave operator satisfies

\[
i \hbar \dot{\Omega}(t) = [H(t), \Omega(t)] \Omega(t) + i \hbar \Omega(t) \dot{\Omega}(t) \quad \Omega(0) = P_0(0)
\]

This wave operator can be used to treat an almost adiabatic dynamics where the dynamics does not escape too far from the instantaneous eigenspace, i.e. \(\forall t, \text{dist}_{\mathcal{F}_S}(P(t), P_0(t)) < \frac{\pi}{2}\). Let \(H^{\text{eff}}(t) = \Omega(t)^{-1} H(t) \Omega(t) \in \mathcal{L}(\text{Ran} P_0(t))\) be the effective Hamiltonian within \(\text{Ran} P_0(t)\). Let \(\{\phi_{ba}(t) \in \text{Ran} P_0(t)\}_{a=1,...,m}\) be a complete set of eigenvectors of \(H^{\text{eff}}(t)\) (for the sake of simplicity, we consider here that \(H^{\text{eff}}\) is diagonalizable), associated with the eigenvalues \(\{\lambda_{ba}^{\text{eff}}(t)\}_{a=1,...,m}\). Let \(\psi(t)\) be the true wave function which is the solution of the Schrödinger equation \(i \hbar \partial_t \psi(t) = H(t) \psi(t)\) with \(\psi(0) = \phi_{ba}(0)\). Since \(\text{dist}_{\mathcal{F}_S}(P(t), P_0(t)) < \frac{\pi}{2}\) we wan write that \(\psi(t) = \sum_{b=1}^m c_b(t) \Omega(t) \phi_{ba}(t)\). By injected this expression in the Schrödinger equation, we find that

\[
\psi(t) = \sum_{b=1}^m \left[ \mathcal{T} e^{-i \int_0^t E^{\text{eff}}(t') dt'} - \int_0^t A(t') dt' - \int_0^t \eta(t') dt' \right]_{ba} \Omega(t) \phi_{ba}(t)
\]
where $Te$ is the time ordered exponential (the Dyson series) and where the matrices $E_{\text{eff}}, A, \eta \in \mathcal{M}_{m \times m}(\mathbb{C})$ are defined by

\begin{align}
E_{\text{eff}}(t) &= \text{diag}(\lambda_{1}^\text{eff}(t), \ldots, \lambda_{m}^\text{eff}(t)) \\
A(t) &= (Z_{0}(t)\dagger Z_{0}(t))^{-1}Z_{0}(t)\dagger \partial_{t}Z_{0}(t) \\
\eta(t) &= (Z_{0}(t)\dagger Z_{0}(t))^{-1}\partial_{t}Ω(t)^{-1}Ω(t)Z_{0}(t)
\end{align}

where $Z_{0}(t) \in \mathcal{M}_{n \times m}(\mathbb{C})$ is the matrix representing $(\phi_{01}(t), \ldots, \phi_{0m}(t))$ in a fixed orthonormal basis of $\mathcal{H} \simeq \mathbb{C}^{n}$ (if $\mathcal{H}$ is infinite dimensional, $Z_{0}(t) \in (\ell^{2}(\mathbb{N}))^{\otimes m}$, where $\ell^{2}(\mathbb{N})$ denotes the square integrable sequences representing the coefficients of the decomposition of the states of $\mathcal{H}$ on a fixed orthonormal basis). $A$ and $\eta$ are the generators of two kinds of non-abelian geometric phases. The next section discusses the geometric structure in which they take place.

Remark: the geometric structure associated with usual time-dependent wave operators $P(t)P_{0}P(t)P_{0}^{-1}$ (with $\dot{P}_{0} = 0$) has been studied in [41]. The present work focuses on the generalized time-dependent wave operators ($\dot{P}_{0} \neq 0$).

### 6.2 The category of the $m$-dimensional subspaces

Before introducing the affine 2-space of the wave operators, we need to introduce an intermediate category.

We denote by $\mathcal{L}_{m}^{\infty}(\mathcal{H})$ the set of rank $m$ linear operators of $\mathcal{H}$. For an endomorphism $f \in \mathcal{L}_{m}^{\infty}(\mathcal{H})$ we consider the decomposition $\ker f \oplus \ker f^{\perp}$ where $\dim \ker f^{\perp} = \dim \text{Ran} f = m$. We introduce moreover the set

$$\mathcal{L}_{m}^{1}(\mathcal{H}) = \{ f \in \mathcal{L}_{m}^{\infty}(\mathcal{H}), \text{dist}_{FS}(\ker f^{\perp}, \text{Ran} f) < \frac{\pi}{2} \}$$

and $\forall q \in \mathbb{N}^{\ast}$ we set

$$\mathcal{L}_{m}^{q}(\mathcal{H}) = \{(f_{q}, \ldots, f_{1}) \in (\mathcal{L}_{m}^{1}(\mathcal{H}))^{q}, \text{Ran} f_{i} = \ker f_{i+1}^{\perp}\}/\chi$$

where the equivalence relation is defined by

$$(f_{q}, \ldots, f_{1}) \sim_{\chi} (f'_{q}, \ldots, f'_{1}) \iff \begin{cases}
\chi(f_{q}, \ldots, f_{1}) = \chi(f'_{q}, \ldots, f'_{1}) \\
\text{Ran} f_{i} = \text{Ran} f'_{i}, \forall i
\end{cases}$$

with $\chi(f_{q}, \ldots, f_{1}) = f_{q} \ldots f_{1}$ (the products being the operator composition).

Let $\mathcal{E}$ be the category defined by

- $\text{Obj}(\mathcal{E})$ are the $m$-dimensional vector subspaces of $\mathcal{H}$.
- $\text{Morph}(\mathcal{E}) = \bigsqcup_{q=1}^{\infty} \mathcal{L}_{m}^{q}(\mathcal{H})$ (we note that $\chi(\text{Morph}(\mathcal{E})) = \mathcal{L}_{m}^{\infty}(\mathcal{H})$).
• \( \forall E \in \text{Obj}(E), \text{id}_E = P_E \) (the orthogonal projection on \( E \)).

• \( \forall f \in \text{Morph}(E), s(f) = \ker \chi(f) \) and \( t(f) = \text{Ran} \chi(f) \).

• \( \forall f, g \in \text{Morph}(E) \) such that \( \text{Ran} \chi(f) = \ker \chi(g) \); \( g \circ f = [g_q, ..., g_1, f_p, ..., f_i]_\chi \)

where \( g = [g_q, ..., g_1]_\chi \), \( f = [f_p, ..., f_i]_\chi \), \([i]_\chi\) denoting the equivalence class associated with \( \sim_\chi \).

### 6.3 The affine 2-space of the wave operators

Let \((\mathcal{M}, \mathcal{R}, \Omega)\) be the hyperbolic affine 2-space defined by

- \( \text{Obj}(\mathcal{M}) = G_m(\mathcal{H}). \)

- \( \forall P, Q \in G_m(\mathcal{H}), \ P R Q \iff \text{dist}_{FS}(P, Q) < \frac{\pi}{2}. \)

- \( \text{Morph}(\mathcal{M}) = \{ P_q(P_{q-1}P_{q-1})^{-1}...P_1P_1 \}^{-1}, P_i \in G_m(\mathcal{H}), \text{dist}_{FS}(P_i, P_i) < \frac{\pi}{2}, q \in \mathbb{N}^+ \}\)

- \( \Omega(P_q, ..., P_1) = P_q(P_{q-1}P_{q-1})^{-1}...P_1P_1^{-1} = \sum_{q} P_q...P_1. \)

- \( s(P_q(P_{q-1}P_{q-1})^{-1}...P_1P_1^{-1}) = \text{Ran} P_1, t(P_q(P_{q-1}P_{q-1})^{-1}...P_1P_1^{-1}) = \text{Ran} P_q, \text{id}_P = P(PPP)^{-1} = P. \)

- The arrow composition is just the operator composition applied on the wave operators.

Let \( \varpi \in \text{Funct}(\mathcal{E}, \mathcal{M}) \) be the functor consisting to transform the vector spaces into their orthogonal projectors, and such that

\[
\varpi([f_q, ..., f_i]_\chi) = P_{\text{Ran} f_q}(P_{\text{Ran} f_q-1}P_{\text{Ran} f_q-1})^{-1}...P_{\text{Ran} f_i}P_{\text{Ran} f_i}P_{\text{Ran} f_i}^{-1}
\]

\( P_{\text{Ran} f_i} \) being the orthogonal projector on \( \text{Ran} f_i \).

Let \( (e_a)_{a=1, ..., n} \) be the chosen orthonormal basis of \( \mathcal{H} \). Let \( \{P_i\}_i \) be the set of the orthogonal projectors on the spaces spanned by \( m \) vectors of \( (e_a)_{a=1, ..., n} \) (\( m \leq n \)). We denote by \( I^i \) the set of the indices of the \( m \) vectors spanning \( \text{Ran} P_i \) (\( \text{Ran} P_i = \text{Span}(e_a; a \in I^i) \)). Let \( U^i \) be the open chart of \( G_m(\mathbb{C}^n) \) defined by

\[
U^i = \{ P \in G_m(\mathbb{C}^n) | \text{dist}_{FS}(P, P_i) < \frac{\pi}{2} \}
\]

\( \{U^i\}_i \) constitutes a good open cover of \( G_m(\mathbb{C}^n) \) and then \( \{U^i\}_i \) generated by \( \Omega \) constitutes a good open 2-cover of \( \mathcal{M} \). \( \forall P \in U^i \), there exists a basis \( (u_a)_{a \in I^i} \) of \( \text{Ran} P \) such that (see \[39\]):

\[
u = e_a + \sum_{b \in I^i} c_{ab} e_b \quad c_{ab} \in \mathbb{C}
\]
The map \( \xi^i : U^i \to \mathbb{C}^{m(n-m)} \) is the coordinates map of \( U^i \). \( \forall P \in U^i \) we denote by \( Z^i_0 \in \mathcal{M}_{m \times n}(\mathbb{C}) \) the matrix representing \((u_1, \ldots, u_m)\) in the basis \((e_a)_{a=1,\ldots,n}\) (we call it the coordinates matrix of \( P \)).

### 6.4 The trivial 2-bundle associated with the wave operators

Let \( \mathcal{P} \) be the category defined by

- \( \text{Obj}(\mathcal{P}) = \{ Z \in \mathcal{M}_{n \times m}(\mathbb{C}), \det(Z^\dagger Z) \neq 0 \} \). \( \text{Obj}(\mathcal{P}) \) can be identified with a complex non-compact Stiefel manifold (see [39]).
- \( \text{Morph}(\mathcal{P}) = \{ (f, Z) \in \text{Morph}(\mathcal{E}) \times \text{Obj}(\mathcal{P}); s(f) = \text{Span}(Z) \} \). (\( \text{Span}(Z) \) denotes the vector space spanned by the vectors represented by \( Z \)).
- \( s(f, Z) = Z; t(f, Z) = \chi(f)Z \) (\( \chi(f)Z \) denotes the matrix in the fixed basis \((e_a)_{a=1,\ldots,n}\) representing the action of \( \chi(f) \) on the \( m \) vectors represented by \( Z \)).
- \( \text{id}_{Z} = (P, Z) \) with \( P = Z(Z^\dagger Z)^{-1}Z^\dagger \) which is the orthogonal projector on \( \text{Span}(Z) \).
- \( (f_2, W) \circ (f_1, Z) = (f_2 \circ f_1, Z) \) with \( W = \chi(f_1)Z \).

Let \( \pi \in \text{Funct}(\mathcal{P}, \mathcal{M}) \) be the functor defined by

\[
\forall Z \in \text{Obj}(\mathcal{P}), \quad \pi(Z) = Z(Z^\dagger Z)^{-1}Z^\dagger \in G_m(\mathbb{C}^n)
\]

and

\[
\forall (f, Z) \in \text{Morph}(\mathcal{P}), \quad \pi(f, Z) = \varpi(f)
\]

\( \mathcal{P} \) constitutes a principal 2-bundle over \( \mathcal{M} \) with projection functor \( \pi \). Its structure groupoid \( \mathcal{G} \) is constituted by \( G \simeq GL(m, \mathbb{C}) \) the group of matrices representing the basis changes on \( \mathbb{C}^m \), and \( H \simeq GL(m, \mathbb{C}) \) the group of matrices representing the rank \( m \) linear operators of \( \mathcal{H} \). \( t \) is then the isomorphism between \( H \) and \( G \), and \( \alpha \) is the conjugation. We can then define the local trivialization equivalences of \( \mathcal{P} \):

\[
\forall P \in G_m(\mathbb{C}^n), g \in G, \quad \phi^i(P, g) = Z^i_0g
\]

with \( Z^i_0 \) the coordinates matrix associated with \( P \).

\[
\forall Z \in \text{Obj}(\mathcal{P}), \quad \bar{\phi}^i(Z) = (Z(Z^\dagger Z)^{-1}Z^\dagger, (Z^i_0Z_0^i)^{-1}Z^i_0Z_0^i)
\]

with \( Z^i_0 \) the coordinates matrix of \( Z(Z^\dagger Z)^{-1}Z^\dagger \). \((Z^i_0Z_0^i)^{-1}Z^i_0Z_0^i\) is the matrix of the transformation between the basis represented by \( Z^i_0 \) and the basis
\[ \forall \Omega \in \text{Morph}(\mathcal{M}), (h, g) \in H \times G, \]
\[ \phi^i(\Omega, h, g) = (Z^i_{0q}h(Z^i_{0q-1})^{-1}Z^i_{0q-1})^\dagger, \]
\[ Z^i_{0q-1}(Z^i_{0q-2})^{-1}Z^i_{0q-2}, \ldots \]
\[ \ldots, Z^i_{02}(Z^i_{01})^{-1}Z^i_{01}, Z^i_0g) \]
where \( \Omega = P_q(P_{q-1}P_qP_{q-1})^{-1}(P_1P_2P_1)^{-1} \) with \( Z^i_0 \) the coordinates matrix of \( \text{Ran } P_j \).

\[ \forall (f, Z) \in \text{Morph}(\mathcal{P}), \]
\[ \tilde{\phi}^i(f, Z) = (\varphi(f), (W^i_0^\dagger W^i_0)^{-1}W^i_0^\dagger \chi(f)Z^i_0, (Z^i_0^\dagger Z^i_0)^{-1}Z^i_0^\dagger Z) \]
where \( Z^i_0 \) is the coordinates matrix of \( P_{\ker \chi(f)} \) and \( W^i_0 \) is the coordinates matrix of \( P_{\text{Ran } \chi(f)} \). We have well \( t\tilde{\phi}^i(f, Z) = \tilde{\phi}^i(t(f, Z)) \) since

\[ (W^i_0^\dagger W^i_0)^{-1}W^i_0^\dagger fZ^i_0 = (W^i_0^\dagger W^i_0)^{-1}W^i_0^\dagger fZ \]

\( \mathcal{P} \) is a categorical generalization of the Stiefel bundle, the classifying universal bundle for the \( GL(m, \mathbb{C}) \)-principal bundles (see [39]).

By definition the \( G \)-transition functions of \( \mathcal{P} \) are such that

\[ \forall P \in U^i \cap U^j, \quad \tilde{\phi}^i(P, e_G) = (P, (Z^i_0^\dagger Z^i_0)^{-1}Z^i_0^\dagger Z^j_0) = (P, g^{ij}(P)) \]
where \( Z^i_0 \) is the coordinates matrix of \( P \). We have then

\[ g^{ij}(P) = (Z^i_0^\dagger Z^i_0)^{-1}Z^i_0^\dagger Z^j_0 \]
The \( H \)-transition functions are such that \( \forall \Omega \in \text{Morph}(\mathcal{P}) \)

\[ \tilde{\phi}^i(\Omega, e_H, e_G) = (\Omega, (W^i_0^\dagger W^i_0)^{-1}W^i_0^\dagger W^j_0(Z^i_0^\dagger Z^j_0)^{-1}Z^i_0^\dagger Z^j_0, \]
\[ (Z^i_0^\dagger Z^i_0)^{-1}Z^i_0^\dagger Z^j_0) \]
\[ \Omega, (W^i_0^\dagger W^i_0)^{-1}W^i_0^\dagger W^j_0(Z^i_0^\dagger Z^j_0)^{-1}Z^i_0^\dagger Z^j_0 \]
\[ h(Q, P) = (W^i_0^\dagger W^i_0)^{-1}W^i_0^\dagger W^j_0(Z^i_0^\dagger Z^j_0)^{-1}Z^i_0^\dagger Z^j_0 \]
The relation between the \( H \)-transition functions and the \( G \)-transition functions is well satisfied:

\[ h^{ij}(Q, P)g^{ij}(P) = g^{ij}(Q)(Z^i_0^\dagger Z^j_0)^{-1}Z^i_0^\dagger (Z^i_0^\dagger Z^j_0)^{-1}Z^i_0^\dagger Z^j_0 \]
\[ = g^{ij}(Q)(Z^i_0^\dagger Z^j_0)^{-1}Z^i_0^\dagger Z^j_0 \]
\[ = g^{ij}(Q) \]
\( \mathcal{P} \) is trivial in the sense where \( h^{ijk}(P) = e_H \) since
\[
g^{ij}(P)g^{jk}(P) = (Z_0^\dagger Z_0)^{-1}Z_0^\dagger Z_0^\dagger (Z_0^\dagger Z_0)^{-1}Z_0^\dagger Z_0
\]
\[
= (Z_0^\dagger Z_0)^{-1}Z_0^\dagger Z_0
\]
(144)

\[ g^{ik}(P) \]

6.5 The 2-connection associated with the geometric phases

The object-bundle of \( \mathcal{P} \) is the Stiefel bundle which can be endowed with its natural connection (the universal connection of the \( GL(m, \mathbb{C}) \)-principal bundles, see the Narasimhan-Ramaman theorems \[42][43\). This connection defines the following \( G \)-gauge potential:
\[
A^i(P) = (Z_0^\dagger Z_0)^{-1}Z_0^\dagger dZ_0^\dagger \in \Omega^1(G_m(\mathcal{H}), \mathfrak{g})
\]
Moreover we endow the arrow-bundle with a connection defining the following \( H \)-gauge potential:
\[
\eta^i(Q, P) = (Z_0^\dagger Z_0)^{-1}Z_0^\dagger (\Omega^{-1}d_{(2)}\Omega) Z_0^i \in \Omega^1(G_m(\mathcal{H})^2/\mathbb{R}, \mathfrak{h})
\]
with \( \Omega = Q(PQP)^{-1} \) and \( \Omega^{-1} = PQ \). Since \( \Omega Z_0^i \) is a matrix representing a basis of \( \text{Ran} \ Q \), \( \exists g \in G \) such that \( W_0^i g^{-1} = \Omega Z_0^i \). We have then
\[
A^i(Q) = g^{-1} \eta^i(Q, P) g + g^{-1} A^i(P) g + g^{-1} dg
\]
The relation between the \( G \)-gauge potential and the \( H \)-gauge potential is then well satisfied (up to a \( G \)-gauge change).

6.6 Horizontal lifts and parallel transport

Let \( t \mapsto P(t) \in G_m(\mathcal{H}) \) be a solution of the Schrödinger-von Neumann equation and \( t \mapsto P_0(t) \in G_m(\mathcal{H}) \) be an eigenprojector of the Hamiltonian. We suppose that the almost adiabatic condition is satisfied, \( \forall t, \text{dist}_{\text{FS}}(P(t), P_0(t)) < \frac{\pi}{2} \). To simplify, we suppose also that \( \forall t, P(t), Q(t) \in U^i \). The generalized time-dependent operator \( t \mapsto \Omega(t) = P(t)(P_0(t)P(t)P_0(t))^{-1} \) constitutes an elementary pseudosurface of \( \mathcal{M} \). The horizontal lift of \( \Omega \) is then
\[
\mathcal{H} \ell^i(\Omega) = \mathbb{P} \mathcal{P}^{-1} \int (P_0(t), P(t))^{(A^i + \eta^i)}
\]
(148)
where
\[
\tilde{A}^i(t) = (Z_0^\dagger(t) Z_0^i(t))^{-1} Z_0^i(t) \partial_t Z_0^i(t)
\]
and
\[ \tilde{\eta}^i(t) = (Z_0^i(t)^\dagger Z_0^i(t))^{-1} Z_0^i(t)^\dagger \Omega^{-1}(t) \dot{\Omega}(t) Z_0^i(t) \]

\( Z_0^i(t) \) is the coordinates matrix of \( \dot{P}_0(t) \). By applying the intermediate representation theorem \([30]\) on eqn. \((126)\) we have

\[ \psi(t) = \sum_{b=1}^{m} \left[ \mathbb{T} e^{-\frac{i}{\hbar} \mathcal{E}^{eff}(t) dt} e^{-\int_0^t A(t') dt'} - \int_0^t \eta(t') dt' \right]_{ba} \Omega(t) \phi_{0b}(t) \]

\[ = \sum_{b=1}^{m} \left[ \mathbb{T} e^{-\frac{i}{\hbar} \mathcal{E}^{eff}(t) dt} g^i(t) \mathbb{T} e^{-\int_0^t \tilde{A}(t') dt'} - \int_0^t \tilde{\eta}(t') dt' g^i(t)^{-1} \right]_{ba} \times \Omega(t) \phi_{0b}(t) \]

\[(149) \]

where \( Z_0(t) = Z_0^i(t) g^i(t) \) (\( Z_0(t) \) is the matrix representing the eigenvectors of \( H^{eff} \)). The geometric phases of an almost adiabatic quantum dynamics is then the horizontal lift of the pseudosurface defined by the generalized time-dependent wave operator. The formula \((126)\) can be then interpreted as being the parallel transport of \( \phi_{0a}(0) \) along the pseudosurface \( \Omega \) in the associated “vector 2-bundle” \( \mathbb{E} \rightarrow \mathcal{M} \), and modified by the conjugated dynamical phase \( \mathbb{T} e^{-\frac{i}{\hbar} \mathcal{E}^{eff}(t') dt'} \);

\[ \mathcal{E}^{eff}(t) = \mathbb{T} e^{-\int_0^t (A(t') + \eta(t')) dt'} \mathcal{E}^{eff}(t) \mathbb{T} e^{\int_0^t (A(t') + \eta(t')) dt'} \]

Finally we can note that the use of an usual time-dependent wave operator (with \( \dot{P}_0 = 0 \)) is just a particular case of the present discussion with a pinched pseudosurface.

7 Conclusion

The categorical bundle structure is extended to the case where the base space is not a trivial category but an affine 2-space. The new structure permits to define horizontal lifts of objects called the pseudosurfaces. For an impervious pseudosurface, we recover horizontal lifts of usual surfaces (surfaces of the first kind supported by the pseudosurface) previously studied by different authors \([19, 20, 21, 22, 23, 24, 25, 26, 27]\). Nevertheless the notion of pseudosurface is more general. The fact that the wave operators of the quantum dynamics can be viewed as (not impervious) pseudosurfaces augurs futur developpements of new kinds of non-abelian geometric phases for quantum systems, particularly for non-hermitian quantum systems where the wave operators seem play an important role \([13]\). Moreover the possibility to study new physical theories (as the string and brane theory) in the
framework of this generalization could be interesting since some attempts to
develop a categorical theory of quantum gravity have been proposed [44][45].
