Abstract—Novel coronavirus has caused a global pandemic which leads to acute respiratory disorder in humans. In this study, analysis of the transmission of communicable COVID19 disease in India is done. The machine learning model presents the comparison of India with other countries during initial phase of virus spread in India. After that its comparison with initial hard-hit countries is also done. Finally, we also performed time series analysis for prediction using prophet for the next seven days showing confirmed, recovered and deaths that will happen.

Keywords—COVID-19, Time series analysis, Prophet, machine learning

I. INTRODUCTION AND RELATED WORK

The novel coronavirus is an ongoing global pandemic which is caused due to acute respiratory syndrome coronavirus 2 (SARS-CoV-2) [1]. It started in December 2019 originated from Wuhan, China [4][6][8]. World health organization (WHO) proclaimed it as a public health emergency of international concerns in early January 2020 and a pandemic in early March 2020 [7][8]. In the month of March COVID-19 pandemic spread across 190 countries and infected 4.2 lakh people where around 16,500 were killed of them. In India, as many as 562 COVID-19 cases were reported till 23rd March 2020. Of those, 37 recovered and 10 died. On March 24, 2020, the prime minister of India Narendra Modi declared a complete 21-day lockdown to combat the quickly spread of the contagious virus. This period was used to boost the healthcare infrastructure. On the other hand, cases of infections were rapidly rising in Germany, Italy, Spain, France, United Kingdom and the United States. Furthermore, led to the massive impact on the global economy and stock markets which can be seen till date. The severe outbreak of COVID-19 turned out to be a major international crisis which has adversely influenced the important aspects of daily life. Then Ministry of Civil Aviation decided to restrict the domestic or international flights in India till 21 day’s lockdown period. Whereas, in highly affected areas people started to stock up on essential goods leading to shortage of essential stuff.

On 25th March, in the afternoon India reported its 9th death due to COVID-19. Fresh cases from states like Manipur, Bihar, Gujrat and Madhya Pradesh were reported by the union ministry of health and family welfare (MoHFW). The coronavirus outbreak continued to spread quickly in tightly knit across all over the country. However, the question that Indians tried to answer was “Will India be able to tackle this pandemic or are they going to witness another Italy, South Korea, Wuhan or even worse”. As the coronavirus cases are increasing day by day, so exponential growth will be observed during its graphical representation. This is because of the replication property of the virus which doubles with every day that passes. Every country is trying to achieve a sigmoid pattern which tells us that even if the country is not able to find a cure for the virus they have boosted their healthcare facilities so that the number of deaths could be less.

Many researchers have conducted research in the field of prediction and forecasting of virus and their spread in case of epidemics and pandemics. Andrea et.al [6] formulated a mathematical expression to predict the H1N1 influenza pandemic spreading. It was found that the pathogen transmissibility, mobility features, transportation network, demographic profile and mixed virus patterns were the deciding factors. Furthermore, result classification was done based on history of travel. Stephen et.al [7] produced a mathematical model to predict disease outbreak with the use of population-mobility data, actual census and land-use. Results were presented by the bipartite graph which maps the total no of visitors, number of locations visited and number of contacts. Then Randi et.al [8] presented the graphical representation based on eigenvector centralization index for the quickly spread of the infectious disease in a primate social network. Moreover, it was based on the interaction between an individual and a group. This model attained 72.6% accuracy. Anjan et.al [9] developed a machine learning model for the prediction for the mortality of heart diseases with the use of Naive Bayesian Classifier. In addition, advanced encryption techniques were also adopted to secure the patient’s data records. Classification accuracy of 84.07% and 98.2% for the patient’s data security was achieved. Olivera et.al [10] designed the Bayesian Monte Carlo probabilistic theory to predict the quickly spread of the infectious diseases. However, this model has a drawback of prior selection and posterior
probabilities. Caroline et.al [11] presented a mathematical model for the prediction of infectious diseases. In this study, spread of the influenza transmission between birds and human were analyzed. Pragmatic form of validation was done to check the accuracy of the mathematical model. Run et.al [12] did the COVID19 disease transmission analysis and as a result predicted the scale of the pandemic, recovery rate along with fatality rate. Song et. al [13] utilized machine learning and statistical methods of which time series was also a part. In the past it was mainly implemented in the area of infectious diseases to predict the monthly incidence of influenza in China. Lee et al. [14] developed a machine learning based time-series model with the collection of weekly time-series flu-related tweet counts which was further utilized to assess the real-time spread of influenza. This model was able to predict the scale of fast spreading of the novel corona virus across India and different countries in the earlier stages. In the proposed work visualizations were done with the use of python high level application programming interface (API) libraries for varied scenarios to derive precise inferences. This model also helped in the prediction of the spread of corona virus using prophet for the next 7 days.

The remainder of this paper was structured as follows. In Section I methodology for model was described in detail. Section III provides the experimental analysis and discussion. Conclusions and future study directions were concluded in section IV.

II. METHODOLOGY

In this section detailed description of proposed method is provided. Initially data set was obtained from John Hopkins Centre of Systems Science and Engineering and Ministry of Health and Family Welfare. Then four tasks were performed as follows: analysis of present condition in India, similar trend to Italy, South Korea and Wuhan, worldwide data exploration and predicting worldwide cases using prophet. Fig. 1. represents the data flow diagram of the machine learning model.

A. Datasets

This research work utilized publically available datasets [15] [16]. The datasets have entries from 30th January 2020 to 25th March 2020. A brief description about them is mentioned in Table 1.

| Dataset Name                  | Entries | Attributes                                      |
|-------------------------------|---------|-------------------------------------------------|
| Covid complete.csv            | 19220   | Province/State, Country/Region, Latitude, Longitude, Confirmed, Death and Recovered. |
| Covid cases in India.xlsx      | 25 states | S.No., Name of State/UT, Total Confirmed cases (Indian National), Total confirmed cases (Foreign National), Cured and Death | |
| IndianCoordinates.xlsx        | 36 states/UT | Name of State/UT, Latitude and Longitude | |

B. Analysis of Present Condition in India

For the analysis of present condition in India we start from very beginning when coronavirus first patient come to India. A time line was prepared for that for increasing number of patients when they crossed the 100, 300 and 500 mark. For finding the total number of cases we combined the Indian and Foreign nationals together to find out total cases (confirmed) and highlighted the states with maximum patients with color codes using python commands.

Total cases = Indian national + Foreign national

To find out the total active cases were moved the total number of cases with number of death and cured patents.

Total Active = Total cases – (Death cases + Cured cases)

Visualization of spread was done geographically using special library named folium in python to show total cases on Indian map. For getting the confirmed and recovered cases per state we created a plot to get the total cases and cured cases per state. Lastly for finding rise in coronavirus cases in India we used plotly library to make interactive graph for finding the trend of increasing cases in India (cumulative) and coronavirus cases on daily basis.

C. Similar Trend to Italy, South Korea and Wuhan

It was observed that initially hard-hit countries at that time were Italy, South Korea and China (Wuhan). Therefore, comparison was done with India. For this purpose, first we found the cumulative cases in each country for which we used plotly. express which was a high level API for creating figures to check which country was closed to achieve the sigmoid pattern. Then we made comparison between the countries based on inferences drawn from trend in cumulative cases. Wuhan was left out because of the results we got in section III. Lastly, we found the trend after crossing the 100 patients mark for comparison of India with other major hit countries like Italy and South Korea.

D. Worldwide Data Exploration

We combined attributes from different datasets to make data of country with date and state name having confirmed, recovered and death cases. As the data has multiple entries with same country name but with different entries. After performing the prior function, we separated the data based on date, latitude, longitude, confirmed, recovered and death cases. Then created
a worldwide case plot with confirmed, recovered and death cases.

E. Predicting Future Worldwide Cases using Prophet

Prophet was used for time series analysis. First, we found out the next seven days for prediction then predicted values of confirmed, recovered and death cases were found out for those days. We plot the predicted values and subplots to check for the trend, similarity and comparisons of our results.

III. RESULTS AND DISCUSSION

From our study of analysis of condition in India Prime Minister of India Narendra Modi speech on 24th March 2020 was a good decision at right time to boost the health care resources in his speech he mentioned the following points:

- Proclaimed a nationwide lockdown for three-week starting midnight Next day he explained that it was mandatory step for controlling the Covid-19 increasing infection cycle.
- Public was appealed to not panic buying stuffs because people began crowding markets to stock up before the midnight deadline.
- The government issued a circular in which it was mentioned that essential services will remain open, as before and all essential commodities and medicines would be available. Banks, ATMs, petrol pumps, hospitals and grocery shops will continue to function.
- All transportation services such as roadways, air and rail were suspended until April 14.

A. Results from Analysis of Present Condition in India

As the background gradient was used therefore the results have highlighted data for the most number of cases for every attribute in data as shown in Fig. 2. The results show that Kerala had the greatest number of patients. The visualization tells about the other important details:

- Manipur and Mizoram reported their first case.
- Kerala has crossed Maharashtra in terms of highest number of confirmed cases.
- Haryana and Telangana had the highest count of confirmed Foreign National count.
- Till 25th of March, 9 people were died in India.
- Kerala, Maharashtra and Karnataka were the currently top three states with maximum number of confirmed cases.

From Fig. 3 it was observed that Kerala was the most affected state in initial phase having less resources with total 105 active cases followed by Maharashtra which had 99 active cases. Whereas, the North Indian region had less number of cases.

Fig. 4 illustrates the visualization spread geographically in India. The result of visualizations was pretty clear which showed the total number of cases at every state. The bigger the circle the greater number of cases present in that region. The top left part of graphs has zoom in and zoom out options.

Fig. 5 shows the confirmed vs recovered cases in India. It was found that net percentage of affected people are less in Kerala than in Maharashtra. Also, it showed that Uttar Pradesh and Haryana healthcare services did well with small amount of 35 and 27 people infected in their states respectively.

---

---
For finding the increasing number of coronavirus cases, a scatter graph with liner and marker sort of visualization and bar graph for Indian scenario was created which showed India in early hit tackled the situation well as after 22nd March they started achieving the sigmoid pattern until the number of patients were low as represented in Fig. 6 and Fig. 7. The visualization has a hover and zoom effect as a particular section was highlighted. It was zoomed to draw more inferences. The zoomable option was available for even the timestamps between the dates.

B. Results from Similar Trend to Italy, South Korea and Wuhan

It was observed that similar trend found in Wuhan, Italy and South Korea inferences from the visualizations. Analysis was described below:

- Fig. 8 showed that the confirmed cases in India raised exponentially with no fixed pattern.
- Fig. 9 provided the information that the confirmed cases in Italy raised exponentially with certain fixed pattern.
- Fig. 10 clearly illustrated that the confirmed cases in South Korea rose gradually.
- From Fig. 11 and Fig. 12 it was observed that there were only 3 confirmed cases in Wuhan in last week. The COVID-19 was almost controlled. The key reason behind the success of stopping the spread of this virus was that baidu’s came up with thermal imaging cameras and it was deployed everywhere possible which helped in picking out people from streets whose temperature was high straight to the hospitals for treatment.

Also, the latest updates from Wuhan came on that day which made our inferences stronger as described below:

- China on Tuesday announced to lift the three-month lockdown on more than 56 million people living in the central province of Hubei.
- Bus services began in Wuhan for the first time since January 23 as a bus departed from its terminus at Hankou railway station at 5:25 am on Wednesday.
- The prolonged lockdown of Hubei’s capital Wuhan will end on April 8, lifting the mass quarantine over the city with a population of over 11 million.
Fig. 8. Confirmed cases in India.

Fig. 9. Confirmed cases in Italy.

Fig. 10. Confirmed cases in South Korea.

Fig. 11. Confirmed cases in Wuhan.

Fig. 12. Confirmed cases in Wuhan close to achieve sigmoid pattern.

Fig. 13. Total confirmed cases (cumulative) for India, Italy and South Korea.

Fig. 14. Trend for India, Italy and South Korea after 100 cases.

Fig. 13 shows the plotting of Italy, India and South Korea scenario. South Korea already started achieving the sigmoid pattern because of theory regressive testing they placed testing booths with proper safety to get people tested. Whereas India and Italy were still on a rise with patients. Wuhan as already close to achieved the sigmoid pattern was left out in this comparison. With the increase in number of cases the graph becomes bluer. The legend on right side of the graph helped in depicting the total cases in countries.

The reason for India testing so little according to CNN Report [16] was due to the less spread of disease among people. As early “evidence” health authorities took 826 samples collected from patients suffering from acute respiratory disease from 50 government hospitals across India between 1st and 15th March which tested negative for coronavirus. Also, hospitals did not report any spike in admissions of respiratory distress cases. India was tested below scale due to the fear of its under-resourced and uneven public health system could be swamped by the patients. But according to the PM announcements it was clear that India was buying time to stock up on testing kits and add isolation and hospital beds [17][18].

Even India had 8 doctors per 10,000 people as compared to 41 in Italy and 71 in Korea in Italy and 71 in Korea. There was one state-run hospital for more than 55,000 people. (Private hospitals were out of reach for most individuals). Another problem was that India had a poor culture of testing and most
of the people with flu symptoms avoid to consult doctors and instead try home remedies or go to pharmacies. There was a scarcity of isolation beds, trained nursing staff, medics, ventilators and intensive care beds.

C. Results of Worldwide Data Exploration

Fig. 15 showed the exploring of the worldwide data. There were 336,004k people which were confirmed of the deadly corona virus from which 98,334k recovered and 14,643k died. Whereas from Fig. 16 it was concluded that between February 12th 2020 and February 13th 2020 there was an increase of confirmed cases in just one day which was abnormal. From our study we found that on 12th February 2020 the main body responsible for researching about coronavirus came up with new method of counting patients which were infected with the virus but on 13th February they realized that the method was wrong and changed it. But till then the cumulative graph for the world scenario for confirmed patients was already altered because of that mistake.

![Fig. 15. Worldwide NCOVID-19 cases for confirmed cases.](image)

![Fig. 16. Increase in confirmed cases between 12th and 13th February.](image)

D. Results of Predicting Future Worldwide Cases using Prophet

The predicted value for confirmed cases on 26th March 2020 came out to be 3,55,136 and for 30th March it came out to be 4,18,529. All predicted values for confirmed cases are mentioned in Table III. The death cases also came down near Wednesday because the number of confirmed cases were predicted to be less at that day which showed the consistency of the graphs as shown in Fig. 20. The forecast for recovered cases was presented in Fig. 21 which showed the most coinciding graph even in exponential increase of predicted and actual cases there was an amazing cohesiveness. The predicted value for recovered cases on 26th March 2020 came out to be 1,03,001 and for 30th March it came out to be 1,13,244. All predicted values for death cases are mentioned in Table IV. The recovered components are plotted in Fig. 22. From the subplots the recovered cases were seen more in Sundays and Mondays because the most number of identified cases according to model were also on Sundays and Mondays. It takes a hit till Friday because of less case and rises on Saturday again. The predicted values for confirmed, death and recovered patients was mentioned in Table 2– 4 respectively.

| Date        | Predicted value | Lower limit | Upper limit |
|-------------|-----------------|-------------|-------------|
| 2020-03-26  | 355336.872975   | 334384.109371 | 375726.515251 |
| 2020-03-27  | 372235.336939   | 349712.320279 | 391835.450565 |
| 2020-03-28  | 388674.961443   | 367308.789183 | 411777.125876 |
| 2020-03-29  | 405307.954676   | 381419.927783 | 428149.690375 |
| 2020-03-30  | 418529.648467   | 395683.667642 | 443064.760034 |

| Date        | Predicted value | Lower limit | Upper limit |
|-------------|-----------------|-------------|-------------|
| 2020-03-26  | 15411.877522    | 14483.880532 | 16355.741169 |
| 2020-03-27  | 16199.617603    | 15223.621567 | 17106.213775 |
| 2020-03-28  | 17006.904589    | 16017.036648 | 17958.214719 |
| 2020-03-29  | 17831.505383    | 16831.699633 | 18852.858632 |
| 2020-03-30  | 18490.986176    | 17455.813093 | 19549.969302 |

| Date        | Predicted value | Lower limit | Upper limit |
|-------------|-----------------|-------------|-------------|
| 2020-03-26  | 103001.351979   | 101349.595952 | 104789.401191 |
| 2020-03-27  | 105338.025206   | 103466.650449 | 107416.338645 |
| 2020-03-28  | 108256.310913   | 106204.627791 | 110231.644632 |
| 2020-03-29  | 111119.296134   | 108721.510751 | 113799.330776 |
| 2020-03-30  | 113244.961701   | 110536.366609 | 116213.952425 |

If we look at the world’s data and its forecast, it is clear to say that India might face one of its worst days if strict measures are not taken against COVID-19. If we look at the data, the number of cases in India is rising but not like in Italy, Wuhan and South Korea. From proposed research work we can say that the number was less because of low awareness and less tests being conducted in India. Currently India is a deadly and risky zone as there are very few COVID-19 test centers in India as compared to its population.

PM Modi announced Janta Curfew in India on 22nd March. From 24th March there is a complete lockdown the entire country. Definitely it was for our own good.
IV. CONCLUSIONS

For proper visualization and to draw accurate inferences it is proved that the proposed model fits the best. The analysis of present condition in India can be performed for any country based on datasets provided of that country. From finding total cases considering the foreign and country national people to finding active cases. Visualizations on maps is the best way to recognize the disease spreads in a country in the results. Covering every state comparison for cases to determine the performance of that state to finding the pattern in raising cases for a particular country is achieved in the results. A global comparison is necessary when we talk about pandemics which
is achieved though the results finding similar trends to other countries followed by exploring the data worldwide. In case of stopping the disease from spreading a proper technique can only be implemented and thought of when we know the coming forecast due to that particular disease which is also achieved in the results. At last only suggestions to India for coming days is to implement regressive testing, use thermal imaging cameras on public places and impose heavy fines on those who break laws which was done by China and other countries.

This model can be used by any country or government organization to non-government organizations who want to know the impact of a virus in worldwide scenario and prepare before to combat it. Results obtained by the model can be used as a reference in finding out the mistakes on country as well as global level.

Future work will be directed towards the analysis on large worldwide datasets and then performing comparison of other countries with India using machine learning models. Further comparing with time series models.
