Abstract. We construct a class of $3 \otimes 3$ entangled edge states with positive partial transposes using indecomposable positive linear maps. This class contains several new types of entangled edge states with respect to the range dimensions of themselves and their partial transposes.

1. Introduction

The notion of entanglement in quantum physics has been studied extensively during the last decade in connection with the quantum information theory and quantum communication theory. A density matrix $A$ in $(M_n \otimes M_m)^+$ is said to be entangled if it does not belong to $M_n^+ \otimes M_m^+$, where $M_n^+$ denotes the cone of all positive semi-definite $n \times n$ matrices over the complex fields. A density matrix is said to be separable if it belongs to $M_n^+ \otimes M_m^+$. Recall that a density matrix defines a state on the matrix algebra by the Schur or Hadamard product.

The basic question is, of course, how to distinguish entangled ones among density matrices, or equivalently among states on matrices. For a block matrix $A \in M_n \otimes M_m$, the partial transpose or block transpose $A^\tau$ of $A$ is defined by

$$
\left( \sum_{i,j=1}^m a_{ij} \otimes e_{ij} \right)^\tau = \sum_{i,j=1}^m a_{ji} \otimes e_{ij}.
$$

\textsuperscript{1}This work was partially supported by KOSEF grant R14-2003-006-01002-0.
In the early eighties, it was observed by Choi [7] that the partial transpose of every separable state is positive semi-definite. This necessary condition for separability has been also found independently by Peres [27], and is now called the PPT criterion for separability. Choi [7] also gave an example of $3 \otimes 3$ entangled state whose partial transpose is positive semi-definite. This kind of entangled state is called PPTES.

A positive linear map between matrix algebras is said to be decomposable if it is the sum of a completely positive linear map and a completely copositive linear map. Choi [6] was the first who gave an example of indecomposable positive linear map. Woronowicz [34] showed that every positive linear map from $M_2$ into $M_n$ is decomposable if and only if $n \leq 3$. He showed that there is an indecomposable positive linear map from $M_2$ into $M_4$ by exhibiting an example of $2 \otimes 4$ PPTES. Strørmer [30] also gave a necessary and sufficient condition for decomposability in terms of partial transpose, and gave an example of $3 \otimes 3$ PPTES. During the nineties, bunch of examples of PPTES have been found. See [1], [2], [8], [14], [15], [16] and [29], for examples. Among examples of PPTES, so called edge PPTES play special roles as was studied in [25].

The cone of all positive semi-definite block matrices with positive partial transposes will be denoted by $\mathcal{T}$ in this paper. The facial structures may be explained in terms of duality between the space of linear maps and the space of block matrices, as was studied in [9] which was motivated by the works of Woronowicz [34], Strørmer [30] and Itoh [18]. The cone generated by separable states will be denoted by $\mathcal{V}_1$. Then the above mentioned examples will lie in $\mathcal{T} \setminus \mathcal{V}_1$. A PPTES $A$ in $\mathcal{T} \setminus \mathcal{V}_1$ is an edge PPTES if and only if the proper face of $\mathcal{T}$ containing $A$ as an interior point does not contain a separable state.

Edge states may be classified by their range dimensions as was studied in [29]. An edge PPTES $A$ is said to be an $(s, t)$ edge state if the range dimension of $A$ is $s$, and the range dimension of $A^\tau$ is $t$. Some necessary conditions for possible combination of $(s, t)$ have been discussed in [17] and [29]. In the $3 \otimes 3$ cases, it is quite curious that every known examples of edge PPTES are $(4, 4)$ or $(7, 6)$ edge states. Here, we assume that $s \geq t$ by the symmetry. The purpose of this note is to construct another kinds of $3 \otimes 3$ edge states. More precisely, we construct $(7, 5)$, $(6, 5)$ and $(8, 5)$ edge states as well as $(7, 6)$ and $(4, 4)$ edge states. It seems to be still open if there exists a $(6, 6)$ or $(5, 5)$ edge state. This paper was motivated by the paper [29], where it was conjectured that every $3 \otimes 3$ entangled state has Schmidt number two. This is
equivalent to ask if every 2-positive linear map between $M_3$ is decomposable, by the
duality mentioned above. See [4], Corollary 4.3 and [10] in this direction.

The basic tool is the duality mentioned above. In the Section 2, we briefly recall
the basic notions of the duality, together with the results in [13], [14] which show that
every edge state may be constructed from an indecomposable positive linear map.
Our examples of edge states will be constructed in Section 3 from the indecomposable
maps considered in [4].

Throughout this paper, we will not use bra-ket notations. Every vector will be
considered as a column vector. If $x \in \mathbb{C}^m$ and $y \in \mathbb{C}^n$ then $x$ will be considered as
an $m \times 1$ matrix, and $y^*$ will be considered as a $1 \times n$ matrix, and so $xy^*$ is an $m \times n$
rank one matrix whose range is generated by $x$ and whose kernel is orthogonal to $y$.
For a vector $x$, the notation $\overline{x}$ will be used for the vector whose entries are conjugate
of the corresponding entries. The notation $\langle \cdot, \cdot \rangle$ will be used for bi-linear pairing. On
the other hand, $(\cdot | \cdot)$ will be used for the inner product, which is sesqui-linear, that
is, linear in the first variable and conjugate-linear in the second variable. For natural
numbers $m$ and $n$, we denote by $m \lor n$ and $m \land n$ the maximum and minimum of $m$
and $n$, respectively.

2. Decomposable maps and PPT entanglement

For a given finite set $V = \{V_1, V_2, \ldots, V_\nu\} \subset M_{m \times n}$ of $m \times n$ matrices, we define
linear maps $\phi_V$ and $\phi^V$ from $M_m$ into $M_n$ by the following:

$$\phi_V : X \mapsto \sum_{i=1}^\nu V_i^* X V_i, \quad X \in M_m,$$

$$\phi^V : X \mapsto \sum_{i=1}^\nu V_i^* X^t V_i, \quad X \in M_m,$$

where $X^t$ denotes the transpose of $X$. We denote by $\phi_V = \phi_{\{V\}}$ and $\phi^V = \phi^{\{V\}}$.
It is well-known [3], [24] that every completely positive (respectively completely
copositive) linear map between matrix algebras is of the form $\Phi_V$ (respectively $\Phi^V$).
We denote by $\mathbb{P}_{m \land n}$ (respectively $\mathbb{P}^{m \land n}$) the convex cone of all completely positive
(respectively completely copositive) linear maps. For a subspace $E$ of $M_{m \times n}$, we define

$$\Phi_E = \{ \phi_V \in \mathbb{P}_{m \land n} : \text{span } V \subset E \},$$

$$\Phi^E = \{ \phi^V \in \mathbb{P}^{m \land n} : \text{span } V \subset E \},$$
where span \( V \) denotes the span of the set \( V \). We have shown in [21] that the correspondence

\[
E \mapsto \Phi_E \quad \text{(respectively } E \mapsto \Phi^E)\]

gives rise to a lattice isomorphism between the lattice of all subspaces of the vector space \( M_{m \times n} \) and the lattice of all faces of the convex cones \( \mathbb{P}_{m \wedge n} \) (respectively \( \mathbb{P}^{m \wedge n} \)). A linear map in the cone

\[
\mathbb{D} := \text{conv} (\mathbb{P}_{m \wedge n}, \mathbb{P}^{m \wedge n})
\]
is said to be decomposable, where \( \text{conv} (C_1, C_2) \) denotes the convex hull of \( C_1 \) and \( C_2 \). Every decomposable map is positive, that is, sends positive semi-definite matrices into themselves, but the converse is not true. There are many examples of indecomposable positive linear maps in the literature [4], [6], [10], [11], [12], [19], [20], [26], [28], [30], [31], [32], [33]. We have shown in [23] that every face of the cone \( \mathbb{D} \) is of the form

\[
\sigma(D, E) := \text{conv} (\Phi_D, \Phi^E)
\]

for a pair \((D, E)\) of subspaces of \( M_{m \times n} \). This pair of subspaces is uniquely determined under the assumption

\[
(1) \quad \sigma(D, E) \cap \mathbb{P}_{m \wedge n} = \Phi_D, \quad \sigma(D, E) \cap \mathbb{P}^{m \wedge n} = \Phi^E.
\]

We say that a pair \((D, E)\) is a decomposition pair if the set \( \text{conv} (\Phi_D, \Phi^E) \) is a face of \( \mathbb{D} \) with the condition (1). Faces of the cone \( \mathbb{D} \) and decomposition pairs correspond each other in this way. Whenever we use the notation \( \sigma(D, E) \), we assume that \((D, E)\) is a decomposition pair. It is very hard to determine all decomposition pairs. See [3], [22] for the simplest case of \( m = n = 2 \).

Now, we turn our attention to the block matrices, and identify an \( m \times n \) matrix \( z \in M_{m \times n} \) and a vector \( \tilde{z} \in \mathbb{C}^n \otimes \mathbb{C}^m \) as follows: For \( z = [z_{ik}] \in M_{m \times n} \), define

\[
z_i = \sum_{k=1}^{n} z_{ik} e_k \in \mathbb{C}^n, \quad i = 1, 2, \ldots, m,
\]

\[
\tilde{z} = \sum_{i=1}^{m} z_i \otimes e_i \in \mathbb{C}^n \otimes \mathbb{C}^m.
\]

Then \( z \mapsto \tilde{z} \) defines an inner product isomorphism from \( M_{m \times n} \) onto \( \mathbb{C}^n \otimes \mathbb{C}^m \). We also note that \( \tilde{z} \tilde{z}^* \) is a positive semi-definite matrix in \( M_n \otimes M_m \) of rank one. We consider the convex cones

\[
\mathbb{V}_s = \text{conv} \{ \tilde{z} \tilde{z}^* : \text{rank } z \leq s \},
\]

\[
\mathbb{V}^s = \text{conv} \{ (\tilde{z} \tilde{z}^*)^r : \text{rank } z \leq s \}.
\]
for \( s = 1, 2, \ldots, m \wedge n \). By the relation
\[
\tilde{x}y^* \tilde{y}^* = (\bar{y} \otimes x)(\bar{x} \otimes y)^* = \bar{y} \bar{y}^* \otimes xx^*, \quad x \in \mathbb{C}^m, \ y \in \mathbb{C}^n;
\]
we have
\[
\mathbb{V}_1 = M_n^+ \otimes M_m^+.
\]
Therefore, a density matrix in \( M_n \otimes M_m \) is separable if and only if it belongs to the cone \( \mathbb{V}_1 \). If \( z = xy^* \) is a rank one matrix with column vectors \( x \in \mathbb{C}^m, y \in \mathbb{C}^n \) then \( (zz^*)^T = ww^* \) is positive semi-definite with \( w = \bar{xy}^* \) by a direct simple calculation. Therefore, we see \([7], [27]\) that every separable state belongs to the convex cone
\[
T := \mathbb{V}_{m \wedge n} \cap \mathbb{V}^{m \wedge n} = \{ A \in (M_n \otimes M_m)^+ : A^T \in (M_n \otimes M_m)^+ \}.
\]
A block matrix in the cone \( T \) is said to be of positive partial transpose.

It is well known that every face of \( \mathbb{V}_{m \wedge n} = (M_n \otimes M_m)^+ \) and \( \mathbb{V}^{m \wedge n} \) is of the form
\[
\Psi_D = \{ A \in (M_n \otimes M_m)^+ : \mathcal{R}A \subset \bar{D} \},
\]
\[
\Psi_E = \{ A \in M_n \otimes M_m : A^T \in \Psi_E \},
\]
respectively, where \( \mathcal{R}A \) is the range space of \( A \) and \( \bar{D} = \{ \bar{z} \in \mathbb{C}^n \otimes \mathbb{C}^m : z \in D \} \). It is also easy to see that every face of \( T \) is of the form
\[
\tau(D, E) := \Psi_D \cap \Psi_E
\]
for a pair \((D, E)\) of subspaces of \( M_{m \times n} \), as was explained in \([13]\). This pair is uniquely determined under the assumption
\[
(2) \quad \text{int} \tau(D, E) \subset \text{int} \Psi_D, \quad \text{int} \tau(D, E) \subset \text{int} \Psi_E,
\]
where \( \text{int} C \) denote the relative interior of the convex set \( C \) with respect to hyperplane generated by \( C \). We say that a pair \((D, E)\) of subspaces is an intersection pair if it satisfies the assumption \((2)\), and \( \tau(D, E) \neq \emptyset \). We also assume the condition \((2)\) whenever we use the notation \( \tau(D, E) \).

Note that the convex cone \( \mathfrak{D} \) and \( T \) are sitting in the vector space \( \mathcal{L}(M_m, M_n) \) of all linear maps from \( M_m \) into \( M_n \) and the vector space \( M_n \otimes M_m \) of all block matrices. In \([9]\), we have considered the bi-linear pairing between the spaces \( \mathcal{L}(M_m, M_n) \) and \( M_n \otimes M_m \), given by
\[
\langle A, \phi \rangle = \text{Tr} \left[ \left( \sum_{i,j=1}^{m} \phi(e_{ij}) \otimes e_{ij} \right) A^t \right] = \sum_{i,j=1}^{m} \langle \phi(e_{ij}), a_{ij} \rangle,
\]
for \( A = \sum_{i,j=1}^{m} a_{ij} \otimes e_{ij} \in M_n \otimes M_m \) and \( \phi \in \mathcal{L}(M_m, M_n) \), where the bi-linear form in the right-hand side is given by \( \langle X, Y \rangle = \text{Tr} (YX^t) \) for \( X, Y \in M_n \). The main result
of [9] tells us that two cones $D$ and $T$ are dual each other in the following sense:

\[ \phi \in D \iff \langle A, \phi \rangle \geq 0 \text{ for every } A \in T, \]
\[ A \in T \iff \langle A, \phi \rangle \geq 0 \text{ for every } \phi \in D. \]

It was also shown in [9] that the cone $P_s$ (respectively $P^*$) consisting of $s$-positive (respectively $s$-copositive) linear maps is dual to the cone $V_s$ (respectively $V^*$) in the above sense. See also [29]. Some faces of the cone $D$ arise from this duality, and is of the form

\[ \tau(D, E)' := \{ \phi \in D : \langle A, \phi \rangle = 0 \text{ for every } A \in \tau(D, E) \} \]

for a face $\tau(D, E)$ of $T$. If $A$ is an interior point of $\tau(D, E)$ then we have

\[ \tau(D, E)' = A' := \{ \phi \in D : \langle A, \phi \rangle = 0 \}. \]

It is easy to see that

\[ \tau(D, E)' = \sigma(D^\perp, E^\perp). \]

It should be noted that not every face arises in this way even in the simplest case of $m = n = 2$. See [3], [22]. Nevertheless, every face of the cone $T$ arises from this duality. More precisely, it was shown in [13] that every face of the cone $T$ is of the form

\[ \sigma(D, E)' := \{ A \in T : \langle A, \phi \rangle = 0 \text{ for every } \phi \in \sigma(D, E) \} = \tau(D^\perp, E^\perp) \]

for a face $\sigma(D, E)$ of the cone $D$. The following is implicit in [13]. We state here for the clearance.

**Proposition 2.1.** A pair $(D, E)$ of subspaces of $M_{m \times n}$ is an intersection pair if and only if there exists $A \in T$ such that $\mathcal{R}A = \tilde{D}$ and $\mathcal{R}A^\tau = \tilde{E}$. If this is the case then we have

\[ \text{int } \tau(D, E) = \{ A \in T : \mathcal{R}A = \tilde{D}, \mathcal{R}A^\tau = \tilde{E} \}. \]

**Proof.** Let $(D, E)$ be an intersection pair and take $A \in \text{int } \tau(D, E)$. Then $A' = \tau(D, E)' = \sigma(D^\perp, E^\perp)$, and we have $\mathcal{R}A = \tilde{D}$ and $\mathcal{R}A^\tau = \tilde{E}$ by [13] Lemma 1. For the converse, assume that there is $A \in T$ such that $\mathcal{R}A = \tilde{D}$ and $\mathcal{R}A^\tau = \tilde{E}$. Take the intersection pair $(D_1, E_1)$ such that $A \in \text{int } \tau(D_1, E_1)$ Then we have $\mathcal{R}A = \tilde{D}_1$ and $\mathcal{R}A^\tau = \tilde{E}_1$, and so $D = D_1$ and $E = E_1$. The last statement has been already proved. $\Box$

**Corollary 2.2.** If $(D_1, E_1)$ and $(D_2, E_2)$ are intersection pairs then $(D_1 \lor D_2, E_1 \lor E_2)$ is also an intersection pair.
Proof. Take $A_i \in \mathbb{T}$ with $\mathcal{R} A_i = \tilde{D}_i$ and $\mathcal{R} A_i^\tau = \tilde{E}_i$ for $i = 1, 2$. Then we have

$$A_1 + A_2 \in \mathbb{T}, \quad \mathcal{R}(A_1 + A_2) = \tilde{D}_1 \lor \tilde{D}_2, \quad \mathcal{R}(A_1 + A_2)^\tau = \tilde{E}_1 \lor \tilde{E}_2.$$ 

Therefore, we see that $(D_1 \lor D_2, E_1 \lor E_2)$ is an intersection pair. \(\square\)

Now, we have two cones $\mathbb{D} \subset \mathbb{P}_1$ in the space $\mathcal{L}(M_m, M_n)$ and another two cones $\mathbb{V}_1 \subset \mathbb{T}$ in the space $M_n \otimes M_m$. Recall that $\mathbb{P}_1$ denotes the cone of all positive linear maps. The pairs $(\mathbb{D}, \mathbb{T})$ and $(\mathbb{P}_1, \mathbb{V}_1)$ are dual each other, as was explained before. Let $\sigma(D, E)$ be a proper face of the cone $\mathbb{D}$. Then we have the following two cases:

$$\text{int } \sigma(D, E) \subset \text{int } \mathbb{P}_1 \quad \text{or} \quad \sigma(D, E) \subset \partial \mathbb{P}_1,$$

since $\sigma(D, E)$ is a convex subset of the cone $\mathbb{P}_1$, where $\partial C := C \setminus \text{int } C$ denotes the boundary of the convex set $C$. We have shown in [13], [14] that

$$\text{(4)} \quad \text{int } \sigma(D, E) \subset \text{int } \mathbb{P}_1 \iff \sigma(D, E)' \cap \mathbb{V}_1 = \{0\}.$$

Every element $A \in \mathbb{T}$ determines a unique face $\tau(D, E)$ whose interior contains $A$. Then a density block matrix $A \in \mathbb{T}$ is an (entangled) edge state if and only if $\tau(D, E) \cap \mathbb{V}_1 = \{0\}$. Therefore, we conclude the following:

(1) If $\sigma(D, E)$ is a face of $\mathbb{D}$ with $\text{int } \sigma(D, E) \subset \text{int } \mathbb{P}_1$ then every nonzero element in the dual face $\sigma(D, E)'$ gives rise to an entangled edge state up to constant multiplications,

(2) Every edge state arises in this way.

The second claim follows from the fact that every face of the cone $\mathbb{T}$ arises from the duality, as was explained before.

3. Construction of $3 \otimes 3$ PPT entangled edge states

We begin with the decomposable positive linear map $\phi : M_3 \rightarrow M_3$ defined by

$$\phi = \phi_{e_{11}-e_{22}} + \phi_{e_{22}-e_{33}} + \phi_{e_{33}-e_{11}} + \phi_{\mu e_{12}-\lambda e_{21}} + \phi_{\mu e_{23}-\lambda e_{32}} + \phi_{\mu e_{31}-\lambda e_{13}},$$

which lies in $\partial \mathbb{D} \cap \text{int } \mathbb{P}_1$ as was shown in [14], where

$$\lambda \mu = 1, \quad \lambda > 0, \quad \lambda \neq 1.$$

We try to determine the dual face $\tau(D, E) = \{\phi\}'$. This map was originated from indecomposable positive linear maps considered in [1]. We note that $D$ is the 7-dimensional space given by

$$D = \text{span } \{e_{12}, e_{21}, e_{23}, e_{32}, e_{31}, e_{13}, e_{11} + e_{22} + e_{33}\},$$
and $E$ is the 6-dimensional space given by

$$E = \text{span} \{ \lambda e_{12} + \mu e_{21}, \lambda e_{23} + \mu e_{32}, \lambda e_{31} + \mu e_{13}, e_{11}, e_{22}, e_{33} \}.$$ 

Therefore, every matrix $x_i \in E$ is of the form

$$x_i = \rho \circ \sigma_i$$

where

$$\rho = \begin{pmatrix} 1 & \lambda & \mu \\ \mu & 1 & \lambda \\ \lambda & \mu & 1 \end{pmatrix}, \quad \sigma_i = \begin{pmatrix} \xi_i & \alpha_i & \gamma_i \\ \alpha_i & \eta_i & \beta_i \\ \gamma_i & \beta_i & \zeta_i \end{pmatrix},$$

and $\rho \circ \sigma_i$ denotes the Hadamard product of $\rho$ and $\sigma_i$.

It follows that if $X^r = \sum_i \tilde{x}_i \tilde{x}_i^* \in \mathbb{V}_3 \cap \mathbb{V}_3$ belongs to $\tau(D, E)$ then

$$X^r = \sum (\tilde{\rho} \tilde{\rho}^*) \circ (\tilde{\sigma}_i \tilde{\sigma}_i^*) = (\tilde{\rho} \tilde{\rho}^*) \circ Y$$

with

$$\tilde{\rho} \tilde{\rho}^* = \begin{pmatrix} 1 & \lambda & \mu & \mu & 1 & \lambda & \lambda & \mu & 1 \\ \lambda & \lambda^2 & 1 & 1 & \lambda & \lambda^2 & \lambda & 1 & \lambda \\ \mu & 1 & \mu^2 & \mu & 1 & 1 & \mu^2 & \mu \\ 1 & \lambda & \mu & \mu & 1 & \lambda & \lambda & \mu & 1 \\ \lambda & \lambda^2 & 1 & 1 & \lambda & \lambda^2 & \lambda & 1 & \lambda \\ \mu & 1 & \mu^2 & \mu & 1 & 1 & \mu^2 & \mu \\ \lambda & \lambda & \mu & \mu & 1 & \lambda & \lambda & \mu & 1 \end{pmatrix},$$

and $Y = \sum \tilde{\sigma}_i \tilde{\sigma}_i^*$ is given by

$$\begin{pmatrix} (\xi | \xi) & (\xi | \alpha) & (\xi | \gamma) & (\xi | \alpha) & (\xi | \eta) & (\xi | \beta) & (\xi | \gamma) & (\xi | \beta) & (\xi | \zeta) \\ (\alpha | \xi) & (\alpha | \alpha) & (\alpha | \gamma) & (\alpha | \alpha) & (\alpha | \eta) & (\alpha | \beta) & (\alpha | \gamma) & (\alpha | \beta) & (\alpha | \zeta) \\ (\gamma | \xi) & (\gamma | \alpha) & (\gamma | \gamma) & (\gamma | \alpha) & (\gamma | \eta) & (\gamma | \beta) & (\gamma | \gamma) & (\gamma | \beta) & (\gamma | \zeta) \\ (\alpha | \xi) & (\alpha | \alpha) & (\alpha | \gamma) & (\alpha | \alpha) & (\alpha | \eta) & (\alpha | \beta) & (\alpha | \gamma) & (\alpha | \beta) & (\alpha | \zeta) \\ (\eta | \xi) & (\eta | \alpha) & (\eta | \gamma) & (\eta | \alpha) & (\eta | \eta) & (\eta | \beta) & (\eta | \gamma) & (\eta | \beta) & (\eta | \zeta) \\ (\beta | \xi) & (\beta | \alpha) & (\beta | \gamma) & (\beta | \alpha) & (\beta | \eta) & (\beta | \beta) & (\beta | \gamma) & (\beta | \beta) & (\beta | \zeta) \\ (\gamma | \xi) & (\gamma | \alpha) & (\gamma | \gamma) & (\gamma | \alpha) & (\gamma | \eta) & (\gamma | \beta) & (\gamma | \gamma) & (\gamma | \beta) & (\gamma | \zeta) \\ (\beta | \xi) & (\beta | \alpha) & (\beta | \gamma) & (\beta | \alpha) & (\beta | \eta) & (\beta | \beta) & (\beta | \gamma) & (\beta | \beta) & (\beta | \zeta) \\ (\zeta | \xi) & (\zeta | \alpha) & (\zeta | \gamma) & (\zeta | \alpha) & (\zeta | \eta) & (\zeta | \beta) & (\zeta | \gamma) & (\zeta | \beta) & (\zeta | \zeta) \end{pmatrix}.$$
if we denote by $\xi, \eta, \zeta, \alpha, \beta$ and $\gamma$ the vectors whose entries are $\xi_i, \eta_i, \zeta_i, \alpha_i, \beta_i$ and $\gamma_i$, respectively. So, $X = (X^T)^\top$ is of the form

$$
\begin{pmatrix}
(\xi|\xi) & \lambda(\xi|\alpha) & \mu(\xi|\gamma) & \mu(\alpha|\xi) & (\alpha|\alpha) & \mu^2(\alpha|\gamma) & \lambda(\gamma|\xi) & \lambda^2(\gamma|\alpha) & (\gamma|\gamma) \\
\lambda(\alpha|\xi) & \lambda^2(\alpha|\alpha) & \mu(\alpha|\xi) & (\alpha|\alpha) & \mu(\alpha|\alpha) & \mu^2(\alpha|\gamma) & \lambda(\gamma|\xi) & \lambda^2(\gamma|\alpha) & (\gamma|\gamma) \\
\mu(\gamma|\xi) & (\gamma|\alpha) & \mu^2(\gamma|\gamma) & \lambda(\beta|\xi) & \lambda^2(\beta|\beta) & \lambda(\beta|\beta) & \lambda(\beta|\alpha) & \lambda(\beta|\alpha) & (\beta|\beta) \\
\mu(\xi|\alpha) & (\xi|\eta) & \lambda(\xi|\beta) & \mu^2(\alpha|\alpha) & \mu(\alpha|\eta) & (\alpha|\beta) & (\alpha|\alpha) & \mu(\gamma|\eta) & \lambda^2(\gamma|\beta) \\
(\alpha|\alpha) & \lambda(\alpha|\eta) & \lambda^2(\alpha|\beta) & \lambda(\eta|\alpha) & \lambda(\eta|\eta) & \lambda(\eta|\beta) & \mu^2(\beta|\alpha) & \mu(\beta|\eta) & (\beta|\beta) \\
\mu^2(\gamma|\alpha) & \mu(\gamma|\eta) & \lambda(\beta|\beta) & \lambda(\beta|\eta) & \lambda(\beta|\beta) & \lambda^2(\beta|\beta) & \mu(\gamma|\alpha) & \lambda(\gamma|\eta) & \lambda(\gamma|\beta) \\
\lambda(\xi|\gamma) & \lambda(\xi|\beta) & (\xi|\gamma) & (\alpha|\gamma) & \mu^2(\alpha|\beta) & \mu(\alpha|\gamma) & \lambda^2(\gamma|\gamma) & (\gamma|\beta) & \lambda(\gamma|\gamma) \\
\lambda^2(\alpha|\gamma) & (\alpha|\beta) & \lambda(\alpha|\gamma) & \lambda(\eta|\beta) & \mu^2(\beta|\gamma) & \mu(\beta|\gamma) & (\beta|\gamma) & (\beta|\beta) & \lambda(\beta|\beta) \\
(\gamma|\gamma) & \mu^2(\gamma|\beta) & \mu(\gamma|\beta) & \lambda(\beta|\gamma) & \lambda(\beta|\beta) & \lambda(\gamma|\beta) & (\gamma|\beta) & \lambda(\gamma|\beta) & (\gamma|\gamma)
\end{pmatrix}
$$

Now, we consider the condition $X \in (\Phi_D)^\top$ to see that

$$
\langle Y, \vec{\rho}^* \circ \phi^V \rangle = \langle \vec{\rho}^* \circ Y, \phi^V \rangle = \langle X^T, \phi^V \rangle = \langle X, \phi_V \rangle = 0
$$

for any $V \in D^\perp$. Note that any matrix $V$ in $D^\perp$ is of the form

$$
V = \begin{pmatrix}
a_1 & \cdots & \cdots \\
. & a_2 & \cdots \\
. & . & a_3
\end{pmatrix}, \quad a_1 + a_2 + a_3 = 0,
$$

and

$$
\vec{\rho}^* \circ \phi^V = \begin{pmatrix}
|a_1|^2 & \cdots & \cdots \\
. & . & \bar{a}_2 a_1 \\
. & \bar{a}_3 a_1 & \cdots
\end{pmatrix} \cdot \begin{pmatrix}
|a_2|^2 & \cdots & \cdots \\
. & . & \bar{a}_3 a_2 \\
. & \bar{a}_3 a_3 & \cdots
\end{pmatrix} \cdot \begin{pmatrix}
|a_3|^2 & \cdots & \cdots \\
. & . & \bar{a}_3 a_3 \\
. & \bar{a}_3 a_3 & \cdots
\end{pmatrix}
$$

Therefore, it follows that

$$
\begin{pmatrix}
(\xi|\xi) & (\alpha|\alpha) & (\gamma|\gamma) \\
(\alpha|\alpha) & (\eta|\eta) & (\beta|\beta) \\
(\gamma|\gamma) & (\beta|\beta) & (\zeta|\zeta)
\end{pmatrix} \cdot \begin{pmatrix}
|a_1|^2 & \bar{a}_2 a_1 & \bar{a}_3 a_1 \\
\bar{a}_1 a_2 & |a_2|^2 & \bar{a}_3 a_2 \\
\bar{a}_1 a_3 & \bar{a}_2 a_3 & |a_3|^2
\end{pmatrix} = 0
$$

whenever $a_1 + a_2 + a_3 = 0$, where $A \circ B = \sum a_{ij} b_{ij}$ by an abuse of notation. Taking $(a_1, a_2, a_3) = (1, -1, 0)$, we have $\|\xi\|^2 + \|\eta\|^2 = 2\|\alpha\|^2$. But the positivity of the $2 \times 2$ submatrix of $X$ with the 1, 5 columns and rows tells us that $\|\xi\| = \|\eta\| = \|\alpha\|$. 

Similarly, we have

\[ \|\xi\| = \|\eta\| = \|\zeta\| = \|\alpha\| = \|\beta\| = \|\gamma\| = 1 \]

by assuming that \(\|\xi\| = 1\). Hence, \(X\) is of the form

\[
\begin{pmatrix}
1 & \lambda(\xi|\alpha) & \mu(\xi|\gamma) & \mu(\alpha|\xi) & 1 & \mu^2(\alpha|\gamma) & \lambda(\gamma|\xi) & \lambda^2(\gamma|\alpha) & 1 \\
\lambda(\alpha|\xi) & \lambda^2(\xi|\alpha) & (\alpha|\gamma) & (\eta|\xi) & \lambda(\eta|\alpha) & \mu(\eta|\gamma) & \mu(\alpha|\gamma) & (\beta|\gamma) & (\zeta|\xi) & \lambda(\zeta|\alpha) & \mu(\xi|\gamma) \\
\mu(\gamma|\xi) & (\gamma|\alpha) & \mu^2 & \lambda(\beta|\xi) & \lambda^2(\beta|\alpha) & (\beta|\gamma) & (\zeta|\xi) & \lambda(\zeta|\alpha) & \mu(\xi|\gamma) \\
\mu(\xi|\alpha) & (\xi|\eta) & \lambda(\xi|\beta) & \mu(\alpha|\eta) & 1 & \lambda(\eta|\beta) & \mu^2(\beta|\alpha) & \mu(\beta|\eta) & 1 \\
1 & \lambda(\alpha|\eta) & \lambda^2(\alpha|\beta) & \lambda(\alpha|\beta) & 1 & \lambda(\eta|\beta) & \mu^2(\beta|\alpha) & \mu(\beta|\eta) & 1 \\
\mu^2(\gamma|\alpha) & \mu(\gamma|\eta) & (\gamma|\beta) & (\beta|\alpha) & \lambda(\beta|\eta) & \lambda^2 & \mu(\zeta|\alpha) & (\zeta|\eta) & \lambda(\zeta|\beta) \\
\lambda(\xi|\gamma) & \mu(\xi|\beta) & (\xi|\zeta) & (\alpha|\gamma) & \mu^2(\alpha|\beta) & \mu(\alpha|\zeta) & \lambda^2 & (\gamma|\beta) & \lambda(\gamma|\zeta) \\
\lambda^2(\alpha|\gamma) & (\alpha|\beta) & \lambda(\alpha|\beta) & \lambda(\alpha|\beta) & 1 & \lambda(\beta|\zeta) & \lambda^2 & \mu(\beta|\zeta) & 1 \\
1 & \mu^2(\gamma|\beta) & \mu(\gamma|\zeta) & \lambda^2(\beta|\gamma) & 1 & \lambda(\beta|\zeta) & \lambda(\gamma|\zeta) & \mu(\zeta|\beta) & 1 \\
\end{pmatrix}
\]

If we take vectors so that \(\text{span}\{\xi, \eta, \zeta\} \perp \text{span}\{\alpha, \beta, \gamma\}\) with mutually orthonormal vectors \(\alpha, \beta, \gamma\) then we have

\[
X = \begin{pmatrix}
1 & \cdot & \cdot & \cdot & 1 & \cdot & \cdot & \cdot & 1 \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
1 & \cdot & \cdot & \cdot & 1 & \cdot & \cdot & \cdot & 1 \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
1 & \cdot & \cdot & \cdot & 1 & \cdot & \cdot & \cdot & 1 \\
\end{pmatrix}
\]

and

\[
X^\tau = \begin{pmatrix}
1 & \cdot & \cdot & \cdot & (\xi|\eta) & \cdot & \cdot & \cdot & (\xi|\zeta) \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
1 & \cdot & \cdot & \cdot & (\eta|\xi) & \cdot & \cdot & \cdot & (\eta|\zeta) \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
(\zeta|\xi) & \cdot & \cdot & \cdot & (\zeta|\eta) & \cdot & \cdot & \cdot & 1 \\
\end{pmatrix}
\]
We note that the rank of \( X \) is equal to
\[
1 + \text{rank} \left( \begin{pmatrix} \langle \xi | \xi \rangle & \langle \xi | \eta \rangle \\ \langle \eta | \xi \rangle & \langle \eta | \eta \rangle \end{pmatrix} \right) + \text{rank} \left( \begin{pmatrix} \langle \eta | \eta \rangle & \langle \eta | \zeta \rangle \\ \langle \zeta | \eta \rangle & \langle \zeta | \zeta \rangle \end{pmatrix} \right) + \text{rank} \left( \begin{pmatrix} \langle \zeta | \zeta \rangle & \langle \zeta | \xi \rangle \\ \langle \xi | \zeta \rangle & \langle \xi | \xi \rangle \end{pmatrix} \right)
\]
and the rank of \( X^\tau \) is equal to
\[
3 + \text{rank} \left( \begin{pmatrix} \langle \xi | \xi \rangle & \langle \xi | \eta \rangle & \langle \xi | \zeta \rangle \\ \langle \eta | \xi \rangle & \langle \eta | \eta \rangle & \langle \eta | \zeta \rangle \\ \langle \zeta | \xi \rangle & \langle \zeta | \eta \rangle & \langle \zeta | \zeta \rangle \end{pmatrix} \right)
\]
Recall that the rank of the \( n \times n \) matrix \( [(\xi_i | \xi_j)]_{i,j=1}^n \) is the dimension of the space \( \text{span} \{\xi_1, \ldots, \xi_n\} \). If we take mutually independent vectors \( \xi, \eta, \zeta \) then we get a \((7, 6)\) edge state. If we take vectors so that \( \text{dim} \text{span} \{\xi, \eta, \zeta\} = 2 \) and none of two vectors are linearly dependent then we may get a \((7, 5)\) edge state. If we take vectors so that \( \text{dim} \text{span} \{\xi, \eta, \zeta\} = 2 \) and one pair of two vectors are linearly dependent then we have a \((6, 5)\) edge state. Finally, if we take vectors with \( \xi = \eta = \zeta \) then we have a \((4, 4)\) edge state as was given in the paper [14]. For more explicit examples, we put \( \xi = e_1, \eta = e_2 \) in \( \mathbb{C}^3 \). We get one parameter family of \((7, 6)\) edge states (respectively \((7, 5)\) and \((6, 5)\) edge states) if we put
\[
\zeta = e_3, \quad \text{respectively} \quad \zeta = \frac{1}{\sqrt{2}} (e_1 + e_2) \quad \text{and} \quad \zeta = e_1
\]
in the matrix (5).

In order to get another edge states such as \((8, 5)\) edge states, we discard the condition \( X \in (\Phi_{D,\perp})' \). We define vectors \( \xi, \eta, \zeta \in \mathbb{C}^5 \) by
\[
\xi = \sqrt{t} e_1, \quad \eta = \sqrt{t} e_2, \quad \zeta = \sqrt{\frac{1}{t(t+1)}} (\xi + \eta)
\]
for \( t > 1 \). We also take mutually orthonormal vectors \( \alpha, \beta, \gamma \in \mathbb{C}^5 \) in \( \mathbb{C} \) so that
\[
\text{span} \{\xi, \eta, \zeta\} \perp \text{span} \{\alpha, \beta, \gamma\}.
\]
Then we have

$$X = \begin{pmatrix}
    t & \cdots & 1 & \cdots & \cdots & \cdots & \cdots & 1 \\
    \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
    \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
    \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
    \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
    \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
    1 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & 1 \\
    \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots
\end{pmatrix}$$

and

$$X^\tau = \begin{pmatrix}
    t & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
    \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
    \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
    \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
    \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
    \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
    1 & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
    \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots & \cdots
\end{pmatrix}$$

First of all, two matrices

$$\begin{pmatrix}
    t & 1 & 1 \\
    1 & t & 1 \\
    1 & 1 & \frac{2}{t+1}
\end{pmatrix} \quad \begin{pmatrix}
    \lambda^2 & \sqrt{\frac{t}{t+1}} \\
    \frac{\sqrt{t}}{t+1} & \mu^2
\end{pmatrix}, \quad t > 1$$

are positive semi-definite with rank two. It follows that $X$ belongs to $\mathbb{T}$. We note that $\mathcal{R}X$ is an 8-dimensional space spanned by

$$te_{11} + e_{22} + e_{33}, \quad e_{11} + te_{22} + e_{33}, \quad e_{12}, \quad e_{21}, \quad e_{23}, \quad e_{32}, \quad e_{31}, \quad e_{13}$$

and $\mathcal{R}X^\tau$ is a 5-dimensional space spanned by

$$te_{11} + \sqrt{\frac{t}{t+1}}e_{33}, \quad te_{22} + \sqrt{\frac{t}{t+1}}e_{33}, \quad \lambda e_{12} + \mu e_{21}, \quad \lambda e_{23} + \mu e_{32}, \quad \lambda e_{31} + \mu e_{13}.$$
Now, we proceed to show that $X$ is an edge state. It is easy to see that $\mathcal{R}X^\tau$ has following six rank one matrices

$$
\begin{pmatrix}
(t^2 + t)^\frac{1}{4} & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\end{pmatrix}
\begin{pmatrix}
\cdot & \cdot & \cdot \\
\cdot & (t^2 + t)^\frac{1}{4} & \lambda \\
\cdot & \mu & (t^2 + t)^{-\frac{1}{4}} \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\end{pmatrix}
\begin{pmatrix}
i & \lambda & \cdot \\
\cdot & \cdot & \cdot \\
\mu & -i & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\end{pmatrix}
$$

up to scalar multiplication. We note that four matrices in the above list have real entries. If a rank one matrix $xy^* \in \mathcal{R}X^\tau$ is one of them then $xy^* = \overline{xy}^*$. If $xy^* \in \mathcal{R}X^\tau$ is one of the following matrices

$$
\begin{pmatrix}
i e_{11} - ie_{22} + \lambda e_{12} + \mu e_{21}, & -ie_{11} + ie_{22} + \lambda e_{12} + \mu e_{21}, \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\end{pmatrix}
$$

with complex entries, then $\overline{xy}^*$ should be

$$
\begin{pmatrix}
i e_{11} + ie_{22} + \lambda e_{12} - \mu e_{21}, & -ie_{11} - ie_{22} + \lambda e_{12} - \mu e_{21}, \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot \\
\end{pmatrix}
$$

respectively. In both cases, we can show that $\overline{xy}^*$ does not belong to $\mathcal{R}X$ which is spanned by matrices in $\mathcal{R}$. Consequently, there is no rank one matrix $xy^* \in \mathcal{R}X^\tau$ with $\overline{xy}^* \in \mathcal{R}X$. This gives us a two parameter family of $(8, 5)$ edge states.
