Received 24 September, 2013

Abstract. Let $G$ be a finite group. The character degree graph of $G$, which is denoted by $\Gamma(G)$, is the graph whose vertices are the prime divisors of the character degrees of the group $G$ and two vertices $p_1$ and $p_2$ are joined by an edge if $p_1 p_2$ divides some character degree of $G$. In this paper we prove that if $G$ is a simple group of order less that 6000, then $G$ is uniquely determined by its character degree graph and its order. Also by an example we show that this result is not true for all simple groups.

2010 Mathematics Subject Classification: 20C15; 20D05; 20D60

Keywords: character degree graph, character degrees, order, simple group

1. INTRODUCTION AND PRELIMINARY RESULTS

Let $G$ be a finite group, Irr($G$) be the set of irreducible characters of $G$, and denote by $\text{cd}(G)$, the set of irreducible character degrees of $G$.

There are several graphs attached to the set of character degrees of a finite group that have been studied (see [3, 5]). Results on these graphs are often useful to prove results that provide structural information of the group from some property of the set of character degrees. The graph that has been most commonly studied is the graph $\Gamma(G)$ whose vertices are the prime divisors of the character degrees of the group $G$ and two vertices are joined by an edge if the product of the primes divides some character degree of $G$. This graph is called character degree graph and was introduced in [5]. Later this graph has been widely studied (see [4, 6]).

A finite group $G$ is called a $K_3$-group if $|G|$ has exactly three distinct prime divisors. Recently Chen et. al. in [7] proved that these groups are uniquely determined by their orders and one or both of their largest and second largest irreducible character degrees. It is proved that $A_5$, $L_2(7)$, $L_2(17)$, $L_3(3)$ and $U_4(2)$ can be uniquely determined by their orders and the largest degrees of their irreducible characters. Also it is proved that $A_6$ is characterized by its order and the second largest degree of

The first author was in part supported by grants from IPM (No 91050116 and No 92050120).
its irreducible characters. Finally it is proved that $L_2(8)$ and $U_3(3)$ are characterizable by their orders and the largest and the second largest degrees of their irreducible characters.

The goal of this paper is to introduce a new characterization for the simple groups $S$ such that $|S| < 6000$. In fact we prove the following result:

Let $S$ be a simple group such that $|S| < 6000$. If $G$ is a finite group such that $|G| = |S|$ and $\Gamma(G) = \Gamma(S)$, then $G \cong S$.

We note that this result is not true for all simple groups. In fact we give a solvable group of order 6048 such that its order and its character degree graph are the same as $U_3(3)$ and so the simple group of order 6048 is not characterized by its degree graph and its order.

If $N \trianglelefteq G$ and $\theta \in \text{Irr}(N)$, then the inertia group of $\theta$ in $G$ is $I_G(\theta) = \{g \in G \mid \theta^g = \theta\}$. If the character $\chi = \sum_{i=1}^{k} e_i \chi_i$, where for each $1 \leq i \leq k$, $\chi_i \in \text{Irr}(G)$ and $e_i$ is a natural number, then each $\chi_i$ is called an irreducible constituent of $\chi$.

Lemma 1 ((Ito’s Theorem) [2, Theorem 6.15]). Let $A \trianglelefteq G$ be abelian. Then $\chi(1)$ divides $|G : A|$, for all $\chi \in \text{Irr}(G)$.

Lemma 2 ([2, Theorems 6.2, 6.8, 11.29]). Let $N \trianglelefteq G$ and let $\chi \in \text{Irr}(G)$. Let $\theta$ be an irreducible constituent of $\chi_N$ and suppose $\theta_1 = \theta, \ldots, \theta_t$ are the distinct conjugates of $\theta$ in $G$. Then $\chi_N = e \sum_{i=1}^{t} \theta_i$, where $e = [\chi_N, \theta]$ and $t = |G : I_G(\theta)|$. Also $\theta(1) \mid \chi(1)$ and $\chi(1)/\theta(1) \mid |G : N|$.

Lemma 3 ([7, Lemma]). Let $G$ be a nonsolvable group. Then $G$ has a normal series $1 \trianglelefteq H \trianglelefteq K \trianglelefteq G$ such that $K/H$ is a direct product of isomorphic nonabelian simple groups and $|G/K| \mid |\text{Out}(K/H)|$.

Lemma 4 ((Palfy’s Theorem) [4, Theorem 4.1]). Let $\rho(G)$ be the set of all prime divisors of the character degrees of $G$. Let $G$ be a solvable group and $\pi \subseteq \rho(G)$. If $|\pi| \geq 3$, then there exist primes $p, q \in \pi$ and a degree $a \in \text{cd}(G)$ so that $pq$ divides $a$. In other words, any three primes in $\rho(G)$ must have an edge in $\Gamma(G)$ that is incident to two of those primes.

If $n$ is an integer and $r$ is a prime number, then we write $r^a \parallel n$, when $r^a \mid n$ but $r^{a+1} \nmid n$. Also if $r$ is a prime number we denote by $\text{Syl}_r(G)$, the set of Sylow $r$-subgroups of $G$ and we denote by $n_r(G)$, the number of elements of $\text{Syl}_r(G)$. If $H$ is a characteristic subgroup of $G$, we write $H \text{ ch } G$. All other notations are standard and we refer to [1].

2. Main Results

Theorem 1. If $G$ is a finite group of order 60 such that $\Gamma(G) = \Gamma(A_5)$, then $G \cong A_5$.

Proof. We know that $\text{cd}(A_5) = \{1, 3, 4, 5\}$. Therefore $\Gamma(G)$ is a graph with vertex set $\{2, 3, 5\}$ and there is no edge in $\Gamma(G)$. So there exists $\chi \in \text{Irr}(G)$, such that
5 | \chi(1). Also \chi(1)^2 < |G| = 60, implies that \chi(1) = 5. On the other hand, the order
and the character degree graph of G show that 5 is the largest character degree of G.
Therefore G \cong A_5, by [7].

\textbf{Theorem 2.} Let G be a finite group of order 168 and \Gamma(G) = \Gamma(L_2(7)). Then
G \cong L_2(7).

\textbf{Proof.} By [1], We know that cd(L_2(7)) = \{1, 3, 6, 7, 8\}. Therefore \Gamma(G) is a graph
with vertex set \{2, 3, 7\} and there exists an edge between 2 and 3. Similarly to the
proof of Theorem 1 there exists \chi \in \text{Irr}(G) such that \chi(1) = 7. Also there exists
\beta \in \text{Irr}(G) such that 6 | \beta(1). Therefore \beta(1) = 2^\alpha 3, for some \alpha > 0. Then |G| = 168
shows that \beta(1) = 6 or \beta(1) = 12. If \beta(1) = 12, then 1 + \beta(1)^2 + \chi(1)^2 > |G|, which
is a contradiction.

If O_7(G) \neq 1, then O_7(G) is an abelian normal subgroup of order 7 and we get a
contradiction by Ito’s theorem, since \chi(1) = 7. Similarly it follows that O_3(G) = 1.

Now we prove that G is a nonsolvable group. On the contrary let G be a solvable
group. Let M be a normal minimal subgroup of G. By the above discussion M
is a 2-elementary abelian subgroup of G. Also |M| \neq 8, by Ito’s theorem, since
\beta(1) = 6. Hence |M| = 2^k, where 1 \leq k \leq 2. Hence if Q/M \in Syl_7(G/M), then
Q/M \triangleleft G/M. Also if P \in Syl_7(Q), then P ch Q, which implies that P \triangleleft G, and
so O_7(G) \neq 1, which is a contradiction.

Therefore G is nonsolvable and so G has a normal series 1 \leq H \leq K \leq G such
that K/H is a direct product of isomorphic nonabelian simple groups and |G/K| =
|\text{Out}(K/H)|. By the classification of finite simple groups and [1], it follows that
K/H is isomorphic to L_2(7) and so H = 1 and G = K. Therefore G \cong L_2(7).

\textbf{Theorem 3.} Let G be a finite group such that \{|G| = |A_6| = 2^3 3^2 5 and \Gamma(G) =
\Gamma(A_6). Then G \cong A_6.

\textbf{Proof.} By [1], We know that cd(A_6) = \{1, 5, 8, 9, 10\}. Therefore \Gamma(G) is a graph
with vertex set \{2, 3, 5\} and there is an edge between 2 and 5. Similarly to the proof
of Theorem 2 we conclude that G has an irreducible character \chi such that \chi(1) = 10.
Also by Ito’s theorem it follows that O_5(G) = 1.

Let G be a solvable group and M be a normal minimal subgroup of G. Then M
is a p-elementary abelian subgroup, where p = 2 or p = 3. Now we consider two
cases:
\textbf{Case 1.} Let M be a 3-group. Then |M| = 3 or |M| = 9. If |M| = 9, then since 3 is
a vertex of \Gamma(G), we get a contradiction by Ito’s theorem. Therefore |M| = 3. Let
H/M be a Hall subgroup of G/M of order 2^3 5. Then |G/M : H/M| = 3 and so
(G/M)/(L/M) \cong S_3, where L/M = \text{Core}_G(H/M). Therefore 5 | |L/M| and
|L/M| \leq 40, which implies that Q/M \triangleleft L/M, where Q/M \in Syl_3(L/M). Hence
Q \triangleleft G and |Q| = 15. Therefore O_3(G) \neq 1, which is a contradiction.

\textbf{Case 2.} Let M be a 2-group. Since \chi(1) = 10, we get that |M| = 2 or |M| = 4.

(2.1) Let |M| = 4. Then |G/M| = 2 \times 3^2 \times 5.
Let \( H/M \) be a Hall subgroup of \( G/M \) of order \( 3^25 \), which is a normal subgroup of \( G/M \). Also \( Q/M \triangleleft H/M \), where \( Q/M \in \text{Syl}_5(H/M) \), and so \( Q/M \triangleleft G/M \). Therefore \( Q \triangleleft G \) and \( |Q| = 20 \). If \( P \in \text{Syl}_5(Q) \), then \( P \triangleleft G \), which implies that \( O_5(G) \neq 1 \) and this is a contradiction.

(2.2) Therefore \(|M| = 2 \) and \(|G/M| = 2^23^25^2 \). Let \( H/M \) be a Hall subgroup of \( G/M \) of order \( 3^25 \). Then \( |G/M : H/M| = 4 \), and so if \( L/M = \text{Core}_{G/M}(H/M) \), then \((G/M)/(L/M) \triangleleft S_4 \), which implies that \( 5 \) \( |L/M| \). Also \(|L/M||H/M| = 3^25 \). Hence if \( Q/M \in \text{Syl}_5(L/M) \), then similarly to the above, \( Q/M \triangleleft G/M \) and so \( Q \triangleleft G \). Then \( |Q| = 10 \) and if \( P \in \text{Syl}_5(Q) \), then \( P \triangleleft G \), which implies that \( O_5(G) \neq 1 \), and this is a contradiction.

Therefore \( G \) is nonsolvable and so \( G \) has a normal series \( 1 \leq H \leq K \leq G \) such that \( K/H \) is a direct product of isomorphic nonabelian simple groups and \( |G/K| \) \( |\text{Out}(K/H)| \). By the classification of finite simple groups and [1], it follows that \( K/H \) is isomorphic to \( A_5 \) or \( A_6 \).

(i) Let \( K/H \cong A_5 \). Then \( |H| \cdot |G/K| = 6 \) and \( |G/K| \geq 2 \).

(a) Let \( |G/K| = 1 \). Then \( |H| = 6 \). Now consider two cases:

(a.1) Let \( H \cong S_3 \).

Then \( H \triangleleft G \) and so \( C_G(H) \triangleleft N_G(H) = G \). Also \( H \cap C_G(H) = 1 \). Therefore \( G \cong H \times C_G(H) \). Also \( C_G(H) \cong G/H \cong A_5 \) and hence \( G \cong S_3 \times A_5 \). Now \( G \) has an irreducible character of degree 6, which is a contradiction, since 2 and 3 are nonadjacent in \( \Gamma(G) \).

(a.2) Let \( H \cong Z_6 \).

Then there exists \( \theta \in \text{Irr}(H) \) such that \( e = [\chi_H, \theta] \neq 0 \), where \( \chi(1) = 10 \). Hence \( 10 = et \), where \( t = |G : I_G(\theta)| \). We know that \( t \) \( |\text{Aut}(H)| \). If \( t = 1 \), then \( e = 10 \), and so \( [\chi_H, \chi_H] = e^2t = 100 < |G : H| = 60 \), which is a contradiction. Therefore \( t = 2 \) and \( e = 5 \). Since \( H \subseteq I_G(\theta) \), it follows that \( G/H \cong A_5 \) has a subgroup \( I_G(\theta)/H \) such that \( |G/H : I_G(\theta)/H| = 2 \), and this is a contradiction.

(b) Let \( |G/K| = 2 \). Then \( G/H \cong S_3 \) and we get a contradiction, since \( S_3 \) has an irreducible character of degree 6.

(ii) Therefore \( K/H \cong A_6 \) and so \( H = 1 \) and \( G \cong A_6 \).

**Theorem 4.** Let \( G \) be a finite group such that \( |G| = |L_3(3)| = 2^43^313 \) and \( \Gamma(G) = \Gamma(L_3(3)) \). Then \( G \cong L_3(3) \).

**Proof.** By [1], We know that \( \Gamma(G) \) is a complete graph on the vertex set \{2, 3, 13\}. Then there exists \( \chi \in \text{Irr}(G) \), such that \( \chi(1) = 39 \). So by Ito’s theorem we get that \( O_{13}(G) = 1 \).

Let \( G \) be a solvable group. Let \( M \) be a normal minimal subgroup of \( G \). Then \( M \) is a \( p \)-elementary abelian subgroup where \( p = 2 \) or \( p = 3 \). Since there exists \( \beta \in \text{Irr}(G) \) such that \( 6 \mid \beta(1) \), it follows that \( |M| \neq 3^3 \) and \( |M| \neq 2^4 \).

(i) Let \( M \) be a 3-group. Then \( |M| = 3^k \), where \( 1 \leq k \leq 2 \). Then \( |G/M| = 2^43^{3-k}13 \). Let \( H/M \) be a Hall subgroup of \( G/M \) of order \( 2^k13 \). Then \( |G/M : H/M| = 3^{3-k} \) and so \( G/H_G \triangleleft S_9 \) which implies that \( 13 \mid |H_G| \). Let \( Q/M \in
Syl$_{13}(H_G/M)$. Then $Q/M \vartriangleleft G/M$ and so $Q \vartriangleleft G$. If $P \in \text{Syl}_{13}(Q)$, then $P \vartriangleleft G$, which implies that $O_{13}(G) \neq 1$, a contradiction. Therefore $G = M$. By the classification of finite simple groups and [1], it follows that $G$ is a direct product of isomorphic nonabelian simple groups and $j(G) = \{2,3,7,17\}$. Therefore one of the following occurs: $(e',t') = (13,3)$ or $(39,1)$. But in each case we have

$$507 = 13^2 3 \leq e^2 t' \leq |H:M| = 3^3 13,$$

which is a contradiction. Therefore $G$ has a normal series $1 \leq H \leq K \leq G$ such that $K/H$ is a direct product of isomorphic nonabelian simple groups and $|G/K|\mid |\text{Out}(K/H)|$. By the classification of finite simple groups and [1], it follows that $K/H$ is isomorphic to $L_3(3)$. Hence $G \cong L_3(3)$. \hfill $\Box$

**Theorem 5.** Let $q = 8$ or 16. Let $G$ be a finite group such that $|G| = |L_2(q)|$ and $\Gamma(G) = \Gamma(L_2(q))$. Then $G \cong L_2(q)$.

**Proof.**

**Case 1.** Let $q = 8$.

We know that $\text{cd}(L_2(8)) = \{1, 7, 8, 9\}$. Therefore $\Gamma(G)$ is a graph with vertex set $\{2,3,7\}$ and there is no edge in $\Gamma(G)$. So by Lemma 4 we get that $G$ is a nonsolvable group. Therefore $G$ has a normal series $1 \leq H \leq K \leq G$ such that $K/H$ is a direct product of isomorphic nonabelian simple groups and $|G/K|\mid |\text{Out}(K/H)|$. By the classification of finite simple groups and [1], it follows that $K/H$ is isomorphic to $L_2(7)$ or $L_2(8)$. Since $6 \in \text{cd}(L_2(7))$, we get that $K/H \cong L_2(8)$ and so $G \cong L_2(8)$.

**Case 2.** Let $q = 16$.

Similarly to Case 1, by Lemma 4 we get that $G$ is nonsolvable and we get that $G$ has a normal series $1 \leq H \leq K \leq G$ such that $K/H \cong A_5$ or $L_2(16)$. If $K/H \cong A_5$, then $|H| \cdot |G/K| = 2^2 17$ and $|G/K|\mid 2$. Let $P \in \text{Syl}_{17}(H)$. Then $P \vartriangleleft H$, which implies that $O_{17}(G) \neq 1$. Now we get a contradiction by Ito’s theorem since 17 is a vertex of $\Gamma(G)$. Therefore $K/H \cong L_2(16)$ and so $G \cong L_2(16)$. \hfill $\Box$

**Theorem 6.** Let $G$ be a finite group such that $|G| = |A_7| = 2^3 3^2 5 \times 7$ and $\Gamma(G) = \Gamma(A_7)$. Then $G \cong A_7$. 
Proof. The character degree graph of $A_7$ is a complete graph on the vertex set \{2, 3, 5, 7\}. Also there exists $\chi \in \text{Irr}(G)$, such that $21 \mid \chi(1)$.

Let $G$ be a solvable group. Then let $H$ be a Hall subgroup of $G$ of order $2^3 3^2 7$. Then $|G : H| = 5$ and so $G/H \cong S_5$. The order of a solvable subgroup of $S_5$ which is divisible by 5 is a divisor of 20. Let $\theta \in \text{Irr}(H)$ such that $[\chi_{H_G}, \theta] \neq 0$. Then $\chi(1) = et\theta(1)$ and $e$ and $t$ are divisors of $|G : H_G|$, which implies that $e \mid 20$ and $t \mid 20$. Therefore $21 \mid \theta(1)$ and since $\theta(1)^2 < |H_G|$, it follows that $|H_G| = 504$ and so $H = H_G \triangleleft G$. On the other hand, there exists $\eta \in \text{Irr}(G)$ such that $\eta(1) = 35$. Let $\varphi \in \text{Irr}(H)$ such that $[\eta_H, \varphi] \neq 0$. Then $35 = \chi(1) = et\varphi(1)$, where $\varphi(1) \mid |H|$ and $et \mid |G : H| = 5$. Therefore $\theta(1) = 7$ and $et = 5$. Since $[\eta_H, \eta_H] = e^2t \leq |G : H|$, it follows that $e = 1$ and $t = 5$. Hence $H$ has 5 irreducible characters of degree 7. Therefore $1 + 21^2 + 5 \times 7^2 \leq |H| = 504$, which is a contradiction. So $G$ is a nonsolvable group and by Lemma 3, $G$ has a normal series $1 \trianglelefteq H \trianglelefteq K \trianglelefteq G$ such that $K/H$ is a direct product of isomorphic nonabelian simple groups and $|G : K| = |\text{Out}(K/H)|$. By the classification of finite simple groups and [1], it follows that $K/H$ is isomorphic to $A_5$, $A_6$, $A_7$, $L_2(7)$ or $L_2(8)$.

If $K/H \cong A_5$ or $A_6$, then $7 \mid |H|$ and since $|H| \mid 42$, we get that $O_7(G) \neq 1$. Now by Ito’s theorem we get a contradiction, since 7 is a vertex of $\Gamma(G)$.

If $K/H \cong L_2(7)$ or $L_2(8)$, then $5 \mid |H|$ and $|H| \mid 15$, which implies that $O_5(G) \neq 1$ and we get a contradiction by Ito’s theorem.

Finally $K/H \cong A_7$ and so $G \cong A_7$.

\[\square\]

Theorem 7. Let $p \in \{11, 13, 17, 19\}$. If $G$ is a finite group such that $|G| = |L_2(p)|$ and $\Gamma(G) = \Gamma(L_2(p))$. Then $G \cong L_2(p)$.

Proof. Since $p^2 \nmid |G|$, and $p$ is a vertex in the character degree graph of $G$, by Ito’s theorem it follows that $O_p(G) = 1$.

Case 1. Let $p = 11$. Then $|G| = 2^2 \times 3 \times 5 \times 11$.

If $G$ is solvable, let $H$ be a Hall subgroup of $G$ of order $2^2 \times 5 \times 11$. Then $G/H \cong S_5$. Hence $11 \nmid |H_G|$. Now if $P \in \text{Syl}_{11}(G)$, then $P \triangleleft G$, which implies that $O_{11}(G) \neq 1$ and this is a contradiction. Therefore $G$ has a normal series $1 \trianglelefteq H \trianglelefteq K \trianglelefteq G$ such that $K/H$ is isomorphic to $A_5$ or $L_2(11)$. If $K/H \cong A_5$, then $|H|/|G/K| = 11$ and $|G/K| \mid 2$. Then $|H| = 11$ and so $O_{11}(G) \neq 1$, which is a contradiction. Therefore $K/H \cong L_2(11)$ and so $G \cong L_2(11)$.

Case 2. Let $p = 13$. Then if $G$ is a solvable group, let $H$ be a Hall subgroup of $G$ of index 7. Then $13 \mid |H_G|$ and similarly to above $O_{13}(G) \neq 1$, which is a contradiction. Now similarly to above we get that $G \cong L_2(13)$.

Case 3. Let $p = 17$. Then if $G$ is a solvable group, let $H$ be a Hall subgroup of $G$ of index 9. Then $17 \mid |H_G|$ and similarly to the above $O_{17}(G) \neq 1$, which is a contradiction. Now similarly to the above we get that $G \cong L_2(17)$.

Case 4. If $p = 19$, then similarly we get the result.

\[\square\]
Remark 1. The first simple group of order greater than 6000 is $U_3(3)$ of order 6048. In the sequel we show that this group is not characterizable by its character degree graph and its order. We know that the character degrees of $U_3(3)$ are $\{1, 6, 7, 14, 21, 27, 28, 32\}$. So $\Gamma(U_3(3))$ is a complete graph on the three vertices 2, 3 and 7. Now we construct a solvable group $G$ with $|G| = 2^5 3^3 \times 7$ and $\Gamma(G) = \Gamma(U_3(3))$. Let $H$ be the Frobenius group of order $56 = 8 \times 7 = 2^3 \times 7$, and observe that $\text{cd}(H) = \{1, 7\}$. Let $P$ be an extraspecial group of order $3^3$ and exponent 3. It is not difficult to see that $P$ has an automorphism $\sigma$ of order 2 that does not centralize the center of $P$. Let $K$ be the semi-direct product of $\langle \sigma \rangle$ acting on $P$. It is not difficult to see that $|K| = 2 \times 3^3$ and $\text{cd}(K) = \{1, 2, 6\}$. Let $Z$ be a cyclic group of order 2, and take $G = H \rtimes K \rtimes Z$. Then $|G| = 2^5 3^3 \times 7$ and $\text{cd}(G) = \{1, 2, 6, 7, 14, 42\}$. Thus, $\Gamma(G)$ is a complete graph on three vertices.
