The extraction of elastic form factors for mesons in the context of the contact interaction model is revisited in this manuscript. The dressed masses of quarks and mesons are determined through the gap and Bethe-Salpeter equations. The generic elastic scattering process $M\gamma \rightarrow M$ is studied for the meson $M$ formed of two differently flavored quarks. The charge radii of scalar, pseudoscalar, vector and axial-vector mesons are also extracted by virtue of explicit calculation of the meson elastic form factors.

Keywords: Quantum chromodynamics; mesons; elastic form factors.

DOI: https://doi.org/10.31349/SuplRevMexFis.3.0308106

1. Introduction

The correct and precise description of hadron properties from first principles is a very difficult task. Perturbative quantum chromodynamics (QCD) helps us understand with great precision the Standard Model of particle physics in the regime of asymptotic freedom. However, hadrons are manifestations of other emergent properties of QCD, namely, the dynamical chiral symmetry breaking (DCSB) and confinement. A standard method to investigate the internal structure of hadrons is by the extraction of their form factors (FF). The prediction of perturbative QCD for helicity zero meson FF [1], shows that there exists $Q_0 > \Lambda_{\text{QCD}}$, such that

$$Q^2 F_0^\pm (Q^2) > Q_0^2 \approx 16\pi \alpha_s(Q^2) f_0^2 - w_0^2 - (Q^2),$$ (1)

where $f_0^\pm$ is the meson’s leptonic decay constant, $\alpha_s(Q^2)$ is the leading-order strong running-coupling and

$$w_0^\pm (Q^2) = \frac{1}{3} \int_0^1 dx \frac{1}{x} \varphi_0^\pm (x; Q^2),$$ (2)

where $\varphi_0^\pm (x; Q^2)$ is the meson’s dressed-valence-quark parton distribution amplitude. In this work, the elastic scattering process $M\gamma \rightarrow M$ between a meson $M$ and a photon $\gamma$ is analyzed, with the purpose of extracting information on the internal structure of mesons.

We start by providing the key ingredients for the calculation of the FF of mesons in the contact interaction (CI) model. Firstly, the dressed mass of the constituent quarks is calculated in this model. Then, the solution of the Bethe-Salpeter equation (BSE) to compute the meson masses is detailed. Finally, we extract the FF of mesons and determine their charge radii in this unified scheme.

2. Contact interaction and the gap equation

To study the internal structure of mesons in the $M\gamma \rightarrow M$ process, we first need to determine the dressed mass of the quarks which constitute the probed meson. In the CI model, it is calculated through solving the gap equation for the quark propagator, given by

$$S(p, M_q)^{-1} = i\gamma \cdot p + m_q + \int \frac{d^4q}{(2\pi)^4} g^2 D_{\mu\nu}(p-q) \times \frac{\lambda^a}{2} \gamma^\mu S(q, m) \frac{\lambda^a}{2} \Gamma_\nu (q, p),$$ (3)

where $S(p, m) = (p^2 + m^2)^{-1}$ is the quark propagator, $M_q$ is the dressed quark mass, $m_q$ is its current value, $\gamma^\mu$ and $\lambda^a$ are the Dirac and Gell-Mann matrices respectively, $\Gamma_\nu$ is the quark-gluon vertex and $D_{\mu\nu}$ is the gluon propagator. In perhaps the simplest truncation scheme, we consider $\Gamma_\nu \equiv \gamma_\nu$. To solve Eq. (3) analytically, we use the CI model. Hence the gluon propagator takes the form [2],

$$g^2 D_{\mu\nu}(p-q) = \delta_{\mu\nu} \frac{1}{m_G^2},$$ (4)
with \( m_G \) being the gluon mass parameter. The solution of Eq. (3) gives dressed masses of the quarks. They are found by solving the transcendental gap equation,

\[
M_q = m_q + \frac{M_\gamma}{3\pi^2 m_G^2} C^{\mathrm{iu}}(M_q^2),
\]

(5)

where \( C^{\mathrm{iu}}(x) = \frac{1}{1 - x} \) and \( \Gamma(1 - x) \) with \( \Gamma(x) \) the upper incomplete gamma function, and \( \gamma_R \) and \( \gamma_{\mathrm{UV}} \) parameters that regularize the integral [3, 4].

3. Bethe-Salpeter equation

Meson masses are computed through the BSE. This equation, in the CI model, reads as [5],

\[
\Gamma(k; P) = -\frac{4}{3} \frac{1}{m_G^2} \int \frac{d^4 \gamma}{(2\pi)^4} \gamma^\mu \chi(q; P) \gamma^\nu,
\]

(6)

where \( \chi(q; P) = S(q + P)\Gamma(q; P)S(q) \) and \( \Gamma(q; P) \) is the Bethe-Salpeter amplitude (BSA), \( k, \) is the four momentum of the meson. Eq. (3) can be represented diagrammatically as Fig. 1.

We remark that the BSAs are necessary for the calculation of the meson mass. They encode the interaction properties between the meson and its constituent quarks. In the context of the CI, the BSA can be decomposed as,

\[
\Gamma^H(P) = A^H(P)E^H(P) + B^H(P)F^H(P),
\]

(7)

with \( H = S, \) Pseudoscalar (PS), Vector (V) and Axial-Vector (AV).

The coefficients \( A_H \) and \( B_H \) are functions of Dirac matrices, \( P, \) and the reduced mass of the constituent quarks, \( M_R = M_q + M_{\bar{q}}. \) The tensor structure used in this work is shown in Table 1.

In the case of pseudoscalar mesons the BSE can be written in terms of \( E^{\mathrm{PS}} \) and \( F^{\mathrm{PS}} \) as

\[
\left[ \begin{array}{c} E^{\mathrm{PS}}(P) \\ F^{\mathrm{PS}}(P) \end{array} \right] = \frac{4\hat{\alpha}_{\mathrm{IR}}}{3\pi} \left[ \begin{array}{cc} K_{EE}^{\mathrm{PS}} & K_{EF}^{\mathrm{PS}} \\ K_{FE}^{\mathrm{PS}} & K_{FF}^{\mathrm{PS}} \end{array} \right] \left[ \begin{array}{c} E^{\mathrm{PS}}(P) \\ F^{\mathrm{PS}}(P) \end{array} \right],
\]

(8)

### Table 1. BSA for scalar, pseudoscalar, vector and axial-vector mesons. In here, \( \gamma^\mu_t \) satisfies \( \gamma^\mu_t P^\mu = 0. \)

| BSA | \( A(P) \) | \( B(P) \) |
|-----|------------|------------|
| \( \Gamma^S \) | \( i I_D \) | \( - \) |
| \( \Gamma^{\mathrm{PS}} \) | \( i \gamma_5 \) | \( \frac{1}{2m_R} \gamma_5 (\gamma \cdot P) \) |
| \( \Gamma^V \) | \( \gamma_\mu^T \) | \( - \) |
| \( \Gamma_{AV} \) | \( \gamma_5 \gamma_\mu^T \) | \( - \) |

\[ \hat{\alpha}_{\mathrm{IR}} = \alpha_{\mathrm{IR}}/m_q^2 = 1/(4\pi m_G^2) \], with \( m_q = 500 \) MeV the mass of the gluon generated dynamically in QCD [6] and,

\[
K_{EE}^{\mathrm{PS}} = \int_0^1 d\omega \left\{ C^{\mathrm{iu}}(\omega) \right\},
\]

(9)

\[
K_{EF}^{\mathrm{PS}} = \int_0^1 d\omega ((\omega - 1)M_{\gamma} - \alpha(1 - \alpha)P^2 - \omega_1) \bar{C}_1^{\mathrm{iu}}(\omega_1),
\]

(10)

\[
K_{FE}^{\mathrm{PS}} = \int_0^1 d\omega (\alpha M_{\bar{q}} - \alpha M_q) \bar{C}_1^{\mathrm{iu}}(\omega_1),
\]

(11)

\[
K_{FF}^{\mathrm{PS}} = \frac{1}{2} \int_0^1 d\omega ((\omega - 1)M_{\gamma}^2 - M_{\bar{q}}M_{\bar{q}} - \alpha M_q^2)
\]

\[
\times \bar{C}_1^{\mathrm{iu}}(\omega_1),
\]

(12)

where \( \omega_1 = M_{\gamma}^2 - \alpha M_q^2 + \alpha(1 - \alpha)P^2 \) and \( \bar{C}_1^{\mathrm{iu}}(z) = C_1^{\mathrm{iu}}(z)/z = \Gamma(0, z \gamma_{\mathrm{UV}}) - \Gamma(0, z \gamma_{\mathrm{IR}}). \) Finally, the eigenvalue equation, Eq. (8), has a solution at \( P^2 = -m_R^2. \) In the case of vector, axial-vector and scalar mesons, respectively, the BSE read as

\[
K_V(P^2) = \frac{2\hat{\alpha}_{\mathrm{IR}}}{3\pi} \int_0^1 d\omega \left\{ L_{V}(P^2) \bar{C}_1^{\mathrm{iu}}(\omega_1) \right\},
\]

(13)

\[
K_{AV}(P^2) = \frac{2\hat{\alpha}_{\mathrm{IR}}}{3\pi} \int_0^1 d\omega \left\{ L_{V}(P^2) \bar{C}_1^{\mathrm{iu}}(\omega_1) + L_{G}(P^2) \bar{C}_1^{\mathrm{iu}}(\omega_1) \right\},
\]

(14)

\[
K_S(P^2) = \frac{4\hat{\alpha}_{\mathrm{IR}}}{3\pi} \int_0^1 d\omega \left[ L_{G}(P^2) \bar{C}_1^{\mathrm{iu}}(\omega_1) - \left( C_1^{\mathrm{iu}}(\omega_1) - \bar{C}_1^{\mathrm{iu}}(\omega_1) \right) \right],
\]

(15)

**Figure 1.** Diagrammatic representation of the BSE. Blue (solid) circles represent dressed quark propagators S, red (solid) circle is the meson BSA and the blue (solid) rectangle is the dressed-quark-antiquark scattering kernel \( K. \)
where

\[ \mathcal{L}_V(P^2) = M_q^2M_q - (1 - \alpha)M^2_{q'} \]
\[ - \alpha M_q^2 - 2\alpha(1 - \alpha)P^2, \quad (16) \]
\[ \mathcal{L}_G(P^2) = M_q^2M_q + \alpha(1 - \alpha)P^2. \quad (17) \]

The solutions of Eqs. (13)-(15) provide masses of the vector \( (m_V) \), axial-vector \( (m_{AV}) \) and scalar \( (m_S) \) mesons when

\[ 1 + (-1)^j K_j(-m_j^2) = 0, \quad (18) \]

with \( i = \{0, 1, 0\} \) for \( j = \{S, V, AV\} \), respectively.

The procedure described above provides good phenomenological results in the case of vector mesons and flavour non-singlet pseudoscalar meson ground-states [7–11]. For the parity partners, spin-orbit repulsion has to be taken into account [12–16]. In the CI, a phenomenological coupling \( g_{SO} < 1 \) is introduced as a multiplicative common factor to the kernels. The numerical values for mesons with \( J = 0^+, 1^+ \) are [17],

\[ g_{SO}^{0^+} = 0.32, \quad g_{SO}^{1^+} = 0.25. \quad (19) \]

To conclude this section, it is important to remark that the solutions of Eq. (8) and Eqs. (13)-(15) constrain the values of \( E^H \) and \( F^H \). These quantities in turn are crucial in subsequently computing the elastic FF of mesons.

4. Elastic form factors of mesons

Elastic meson FF are calculated from the triangle diagram for \( M\gamma \rightarrow M \), with a quark and an anti-quark circulating in the loop, see Fig. 2. We point out that in this article the meson is considered to be made of two differently flavoured quarks.

Considering that the photon interacts with the quark while the anti-quark is a spectator, Feynman rules permit us to write this process as,

\[ \Lambda_{(\nu)\mu}(\alpha) = 2N_cT \text{r} \left[ i\Gamma^{M}_{(\nu)}(-p_2)S_F(t + p_2, M_\eta)\Gamma_{\mu} \times S_F(t + p_1, M_\eta)\Gamma^M_{(\nu)}(p_1)S_F(t, M_\eta) \right], \quad (20) \]

where \( \Gamma_{\nu} \equiv iP_T(q^2)\gamma^\nu \) is the photon-quark dressed vertex, \( P_T(q^2) \) is the dressing function [18], and the subscript between parentheses indicates that the meson may or may not have Lorentz indices, i.e. \( \Lambda_\mu \) shall be understood for scalar and pseudoscalar mesons and \( \Lambda_{\nu\mu\alpha} \) shall be used for vector and axial-vector mesons. The dressing function is given by

\[ K_\gamma(Q^2) = \frac{1}{3\pi^2m_G} \int_0^1 d\alpha(1 - \alpha)Q^2\bar{G}_{1}(\omega), \quad (21) \]

with \( \omega = M_\eta^2 + \alpha(1 - \alpha)Q^2 \).

In the case of scalar and pseudoscalar mesons, there is only one electromagnetic FF, \( F_{em}^{S,P_S} \). On the other hand, vector and axial-vector mesons have three form factors due to their tensor structure, \( F_{V,AV}^{1,2,3} \) [19]. In terms of these FFs, the electric \( (G_E) \), magnetic \( (G_M) \) and quadrupole \( (G_Q) \) FFs are

\[ G_E = F_1^+ + \frac{2}{3}\eta G_Q, \quad G_M = -F^2, \quad (22) \]
\[ G_Q = F_1^+ + F^2 + (1 + \eta)F^3, \quad (23) \]

where \( \eta \equiv Q^2/(4m_H^2) \) and \( m_H \) is the meson mass. After detailed analytical calculations, all FF can be written as,

\[ F_1^i(Q^2) = \int_0^1 d\alpha d\beta \alpha \times \left( A_1^i \bar{G}_{1}(\omega_2) + (B_2^i - A_2^i \omega_2)\bar{G}_{2}(\omega_2) \right), \quad (24) \]

with \( i = \{S, PS, V, AV\} \) and \( j = \{em\} \) for the scalar and pseudoscalar mesons scenario and \( j = \{1, 2, 3\} \) for the vector and axial-vector mesons case. In addition, \( \bar{G}_{2}(z) = (\exp(-z \tau_{Q}(\nu)) - \exp(-z \tau_{Q}(\bar{\nu})))/(2z) \) and \( \omega_2 = \alpha M_\eta^2 + (1 - \alpha)M_\eta^2 - \alpha(1 - \alpha)M_\eta^2 + \alpha^2 \beta(1 - \beta)Q^2 \).

Naturally, the calculation of the FF also yields information of the magnetic and quadrupole moments for vector and axial-vector mesons, defined as

\[ G_M^i(Q^2 = 0) \equiv \mu_i, \quad G_Q^i(Q^2 = 0) \equiv Q'_i, \quad (25) \]

with \( i = \{V, AV\} \), and these results can be also compared with experimental observation. Note that in the case of mesons composed of differently flavored quarks, we define the meson FF, \( F_i^i \), as the sum of two contributions since the photon can interact either with the quark, \( F_i^q \), or with the anti-quark, \( F_i^{\bar{q}} \). Then [20],

\[ F_i^i(Q^2) = e_q F_i^q(Q^2) + e_{\bar{q}} F_i^{\bar{q}}(Q^2), \quad (26) \]

---

**Figure 2.** Feynman diagram for the \( M\gamma M \) vertex which permits the extraction of elastic meson FF of all mesons. Labelling of internal momenta is included in the diagram.
with $e_q$ and $e_{\bar{q}}$ the quark and anti-quark charges respectively. The procedure described up can readily be adapted for neutral meson with same flavored quarks.

Finally, once the analytic expression of the coefficients $A$ and $B$ are obtained, the comparison between the CI model and the experimental results can also be carried out through the charge radii of different mesons, computed through the relation

$$r_i^2 \equiv \left| \frac{d}{d Q^2} F_i(Q^2) \right|_{Q^2=0}^2, \ i = \{S, PS, V, AV\}. \quad (27)$$

This observable can constrain several models for mesons. The most important feature of the FF is the dependence on $Q^2$. In Ref. [2], it is pointed out that the behaviour of the pion electromagnetic FF at large $Q^2$ tends to a constant value in the CI. For the rho meson, it turns negative for $Q^2 \sim 6$ GeV. In this spirit, it would be interesting to delve into the behaviour of the FF of all kind of mesons in order to understand the predictions of the internal structure through the CI model.

5. Conclusions

In this document, the extraction of the elastic FF of scalar, pseudoscalar, vector and axial-vector mesons in the framework of the CI model has been presented in detail. The determination of the dressed quark and meson masses according to the gap and BSE helps constrain the parameters of the model. The study of the $M \gamma \rightarrow M$ process is presented in order to extract the elastic FF of mesons formed with two differently flavored quarks. Once the general expression is found, the charge radii of scalar, pseudoscalar, vector and axial-vector mesons can also be computed and compared with experimental results. Finally, interesting information such as the magnetic and quadrupole moments can also be obtained in order to establish the extent of validity of the CI model more realistically.
