Paraconsistent logic and query answering in inconsistent databases

C. A. Middelburg

ABSTRACT
This paper concerns the paraconsistent logic $\text{LPQ} \supset F$ and an application of it in the area of relational database theory. The notions of a relational database, a query applicable to a relational database, and a consistent answer to a query with respect to a possibly inconsistent relational database are considered from the perspective of this logic. This perspective enables among other things the definition of a consistent answer to a query with respect to a possibly inconsistent database without resort to database repairs. In an earlier paper, $\text{LPQ} \supset F$ is presented with a sequent-style natural deduction proof system. In this paper, a sequent calculus proof system is presented instead because such proof systems are generally considered more suitable as the basis of proof search procedures than natural deduction proof systems and proof search procedures can serve as the core of algorithms for computing consistent answers to queries.

Relational database; inconsistent database; consistent query answering; paraconsistent logic; sequent calculus

1. Introduction

In the area of relational database theory, often the view is taken in which a database is a theory of first-order classical logic, a query is a formula of first-order classical logic, and query answering amounts to proving in first-order classical logic that a formula is a logical consequence of a theory. In Reiter (1984), the term proof-theoretic view is introduced for this view and various arguments in favour of this view are given. In work on query answering in inconsistent databases based on this view, resort to (consistent) repairs of inconsistent databases is considered unavoidable to come to a notion of a consistent answer to a possibly inconsistent database (see e.g. Arenas et al., 1999). The reason for this is that in classical logic every formula is a logical consequence of an inconsistent theory.

In Bry (1997), the resort to repairs is avoided by switching from first-order classical logic to first-order minimal logic, a logic in which not every formula is a logical consequence of an inconsistent theory. By some shortcomings in Bry (1997), there has been no follow-up of this work. A main shortcoming is that a semantics with respect to which the presented proof system is sound and complete is not given. By that, it remains unclear how the work fits the existing (concrete or abstract) views on what is
a database. Actually, there exists a Kripke semantics of the propositional fragment (see e.g. Colacito et al., 2017), but that semantics seems difficult to relate the existing views on what is a database.

This paper considers consistent query answering from the perspective of LPQ ⊃, F, another first-order logic in which not every formula is a logical consequence of an inconsistent theory. A sequent calculus proof system of LPQ ⊃, F and a three-valued semantics with respect to which the proof system is sound and complete are given. The notions of a relational database, a query applicable to a relational database, and an answer to a query with respect to a relational database are defined in the setting of LPQ ⊃, F. The definitions concerned are based on those given in Reiter (1984). Two notions of a consistent answer to a query with respect to a possibly inconsistent relational database are introduced. One of them is reminiscent of the notion of a consistent answer from Bry (1997) and the other is essentially the same as the notion of a consistent answer from Arenas et al. (1999).

Proof search procedures can serve as the core of algorithms for computing consistent answers to queries. Sequent calculus proof systems are generally considered more suitable as the basis of proof search procedures than Hilbert proof systems and natural deduction proof systems (for the main reasons, see e.g. Negri & von Plato, 2001). That is why a sequent calculus proof system of LPQ ⊃, F is presented in this paper. The proof system of first-order minimal logic presented in Bry (1997) is a natural deduction proof system. Natural deduction proof systems can of course also be used as the basis of proof search procedures, but much less is known about how this can be done. The lack of any remark about proof search procedures for first-order minimal logic is sometimes considered a shortcoming in Bry (1997) as well.

A logic is called a paraconsistent logic if in the logic not every formula is a logical consequence of an inconsistent theory. Priest (1979) proposed the paraconsistent propositional logic LP (Logic of Paradox) and its first-order extension LPQ. LPQ ⊃, F is LPQ enriched with a falsity constant and an implication connective for which the standard deduction theorem holds. LPQ ⊃, F is essentially the same as J∗3 = (D’Ottaviano, 1985) and LP ° (Picollo, 2020). In Middelburg (2020), a sequent-style natural deduction proof system for LPQ ⊃, F is presented. Several main properties of the logical consequence relation and the logical equivalence relation of LPQ ⊃, F are also treated in that paper.

In LPQ ⊃, F, for every inconsistent theory Γ in which the falsity constant F does not occur, for every formula A that does not have function symbols, predicate symbols or free variables in common with Γ, A is a logical consequence of Γ only if A is a logical consequence of the empty theory. In minimal logic, for every inconsistent theory Γ, for every formula A, ¬A is a logical consequence of Γ. Therefore, LPQ ⊃, F is considered a genuine paraconsistent logic and minimal logic is not considered a genuine paraconsistent logic (cf. Odintsov, 2007). Moreover, the properties of LPQ ⊃, F treated in Middelburg (2020) indicate among other things that the logical consequence relation and the logical equivalence relation of LPQ ⊃, F are very close to those of classical logic. That is why the choice has been made to consider in this paper query answering in inconsistent databases from the perspective of LPQ ⊃, F.

The structure of this paper is as follows. First, the language of LPQ ⊃, F, a sequent calculus proof system of LPQ ⊃, F, and a three-valued semantics of LPQ ⊃, F are presented
(Sections 2–4). Next, relational databases and query answering in possibly inconsistent relational databases are considered from the perspective of LPQ\(\supset, F\) (Sections 5 and 6). After that, examples of query answering are given and some remaining remarks about consistent query answering are made ((Sections 7 and 8). Finally, some concluding remarks are made (Section 9).

2. The language of LPQ\(\supset, F\)

This section concerns the language of the first-order paraconsistent logic LPQ\(\supset, F\). First the notion of a signature is introduced and then the terms and formulas of LPQ\(\supset, F\) are defined relative to a signature. Moreover, some relevant notational conventions and abbreviations are presented and some remarks about free variables and substitution are made. In coming sections, many other notions relevant to LPQ\(\supset, F\) are also defined relative to a signature.

Signatures

It is assumed that the following has been given: (a) a countably infinite set \(Var\) of variables, (b) for each \(n \in \mathbb{N}\), a countably infinite set \(Func_n\) of function symbols of arity \(n\), and, (c) for each \(n \in \mathbb{N}\), a countably infinite set \(Pred_n\) of predicate symbols of arity \(n\). It is also assumed that all these sets and the set \(\{=, \neg, \wedge, \vee, \supset, \forall, \exists\}\) are mutually disjoint.

Function symbols of arity 0 are also known as constant symbols and predicate symbols of arity 0 are also known as proposition symbols.

A signature \(\Sigma\) is a subset of \(\bigcup\{Func_n \mid n \in \mathbb{N}\} \cup \bigcup\{Pred_n \mid n \in \mathbb{N}\}\). We write \(Func_n(\Sigma)\) and \(Pred_n(\Sigma)\), where \(\Sigma\) is a signature and \(n \in \mathbb{N}\), for the sets \(\Sigma \cap Func_n\) and \(\Sigma \cap Pred_n\), respectively.

Below the language of LPQ\(\supset, F\) will be defined relative to a signature \(\Sigma\). This language will be called the language of LPQ\(\supset, F\) over \(\Sigma\) or shortly the language of LPQ\(\supset, F\) (\(\Sigma\)). The corresponding proof system and logical consequence relation will be called the proof system of LPQ\(\supset, F\) (\(\Sigma\)) and the logical consequence relation of LPQ\(\supset, F\) (\(\Sigma\)).

Terms and formulas

The language of LPQ\(\supset, F\) (\(\Sigma\)) consists of terms and formulas. They are constructed according to the formation rules given below.

The set of all terms of LPQ\(\supset, F\) (\(\Sigma\)), written \(\text{Term}(\Sigma)\), is inductively defined by the following formation rules:

1. if \(x \in Var\), then \(x \in \text{Term}(\Sigma)\);
2. if \(c \in Func_0(\Sigma)\), then \(c \in \text{Term}(\Sigma)\);
3. if \(f \in Func_{n+1}(\Sigma)\) and \(t_1, \ldots, t_{n+1} \in \text{Term}(\Sigma)\), then \(f(t_1, \ldots, t_{n+1}) \in \text{Term}(\Sigma)\).

The set of all closed terms of LPQ\(\supset, F\) (\(\Sigma\)) is the subset of \(\text{Term}(\Sigma)\) that can be formed by applying formation rules 2 and 3 only.

The set of all formulas of LPQ\(\supset, F\) (\(\Sigma\)), written \(\text{Form}(\Sigma)\), is inductively defined by the following formation rules:
(1) $F \in \text{Form}(\Sigma)$;
(2) if $p \in \text{Pred}_0(\Sigma)$, then $p \in \text{Form}(\Sigma)$;
(3) if $P \in \text{Pred}_{n+1}(\Sigma)$ and $t_1, \ldots, t_{n+1} \in \text{Term}(\Sigma)$, then $P(t_1, \ldots, t_{n+1}) \in \text{Form}(\Sigma)$;
(4) if $t_1, t_2 \in \text{Term}(\Sigma)$, then $t_1 \equiv t_2 \in \text{Form}(\Sigma)$;
(5) if $A \in \text{Form}(\Sigma)$, then $\neg A \in \text{Form}(\Sigma)$;
(6) if $A_1, A_2 \in \text{Form}(\Sigma)$, then $A_1 \land A_2, A_1 \lor A_2, A_1 \supset A_2 \in \text{Form}(\Sigma)$;
(7) if $x \in \text{Var}$ and $A \in \text{Form}(\Sigma)$, then $\forall x \cdot A, \exists x \cdot A \in \text{Form}(\Sigma)$.

The set of all atomic formulas of LPQ$^{\geq F}(\Sigma)$ is the subset of $\text{Form}(\Sigma)$ that can be formed by applying formation rules 1–4 only.

For the connectives $\neg$, $\land$, $\lor$, and $\supset$ and the quantifiers $\forall$ and $\exists$, the classical truth-conditions and falsehood-conditions are retained. Except for implications, a formula is classified as both-true-and-false exactly when it cannot be classified as true or false by the classical truth-conditions and falsehood-conditions.

We write $e_1 \equiv e_2$, where $e_1$ and $e_2$ are terms from $\text{Term}(\Sigma)$ or formulas from $\text{Form}(\Sigma)$, to indicate that $e_1$ is syntactically equal to $e_2$.

Notational conventions and abbreviations
The following will sometimes be used without mentioning (with or without decoration): $x$ as a meta-variable ranging over all variables from $\text{Var}$, $t$ as a meta-variable ranging over all terms from $\text{Term}(\Sigma)$, $A$ as a meta-variable ranging over all formulas from $\text{Form}(\Sigma)$, and $\Gamma$ as a meta-variable ranging over all finite sets of formulas from $\text{Form}(\Sigma)$.

The string representation of terms and formulas suggested by the formation rules given above can lead to syntactic ambiguities. Parentheses are used to avoid such ambiguities. The need to use parentheses is reduced by ranking the precedence of the logical connectives $\neg$, $\land$, $\lor$, $\supset$. The enumeration presents this order from the highest precedence to the lowest precedence. Moreover, the scope of the quantifiers extends as far as possible to the right and $\forall x_1 \cdot \cdots \cdot \forall x_n \cdot A$ is usually written as $\forall x_1, \ldots, x_n \cdot A$.

The following abbreviation is used: $T$ stands for $\neg F$.

Free variables and substitution
Free variables of a term or formula and substitution for variables in a term or formula are defined in the usual way.

Let $x$ be a variable from $\text{Var}$, $t$ be a term from $\text{Term}(\Sigma)$, and $e$ be a term from $\text{Term}(\Sigma)$ or a formula from $\text{Form}(\Sigma)$. Then we write $[x := t]e$ for the result of substituting the term $t$ for the free occurrences of the variable $x$ in $e$, avoiding (by means of renaming of bound variables) free variables becoming bound in $t$.

3. A proof system of LPQ$^{\geq F}(\Sigma)$
In this section, a sequent calculus proof system of LPQ$^{\geq F}(\Sigma)$ is presented. This means that the inference rules have sequents as premises and conclusions. First, the notion of a sequent is introduced. Then, the inference rules of the proof system of LPQ$^{\geq F}(\Sigma)$ are presented. After that, the notion of a derivation of a sequent from a set of sequents
and the notion of a proof of a sequent are introduced. An extension of the proof system of \( \text{LPQ}^{\Sigma} \) which can serve as a proof system for first-order classical logic is also described.

**Sequents**
In \( \text{LPQ}^{\Sigma} \), a sequent is an expression of the form \( \Gamma \Rightarrow \Delta \), where \( \Gamma \) and \( \Delta \) are finite sets of formulas from \( \text{Form}(\Sigma) \). We write \( \Gamma, \Gamma' \) for \( \Gamma \cup \Gamma' \) and \( A \), where \( A \) is a formula from \( \text{Form}(\Sigma) \), for \( \{ A \} \) on both sides of a sequent. Moreover, we write \( \Rightarrow \Delta \) instead of \( \emptyset \Rightarrow \Delta \).

Informally speaking, a sequent \( \Gamma \Rightarrow \Delta \) expresses that, if every formula from \( \Gamma \) is not false, at least one formula from \( \Delta \) is not false.

**Rules of inference**
The sequent calculus proof system of \( \text{LPQ}^{\Sigma} \) consists of the inference rules given in Table 1. In this table, \( x \) and \( y \) are meta-variables ranging over all variables from \( \text{Var} \), \( t \), \( t_1 \), and \( t_2 \) are meta-variables ranging over all terms from \( \text{Term}(\Sigma) \), \( A \), \( A_1 \), and \( A_2 \) are meta-variables ranging over all formulas from \( \text{Form}(\Sigma) \), and \( \Gamma \), \( \Gamma' \), \( \Delta \), and \( \Delta' \) are meta-variables ranging over all finite sets of formulas from \( \text{Form}(\Sigma) \).

**Derivations and proofs**
In \( \text{LPQ}^{\Sigma} \), a derivation of a sequent \( \Gamma \Rightarrow \Delta \) from a finite set of sequents \( \mathcal{H} \) is a finite sequence \( \langle s_1, \ldots, s_n \rangle \) of sequents such that \( s_n \) equals \( \Gamma \Rightarrow \Delta \) and, for each \( i \in \{1, \ldots, n\} \), one of the following conditions holds:

- \( s_i \in \mathcal{H} \);
- \( s_i \) is the conclusion of an instance of some inference rule from the proof system of \( \text{LPQ}^{\Sigma} \) whose premises are among \( s_1, \ldots, s_{i-1} \).

A proof of a sequent \( \Gamma \Rightarrow \Delta \) is a derivation of \( \Gamma \Rightarrow \Delta \) from the empty set of sequents. A sequent \( \Gamma \Rightarrow \Delta \) is said to be provable if there exists a proof of \( \Gamma \Rightarrow \Delta \).

An inference rule that does not belong to the inference rules of some proof system is called a derived inference rule if there exists a derivation of the conclusion from the premises, using the inference rules of that proof system, for each instance of the rule.

Let the set \( \Gamma_e \) of equality axioms be the subset of \( \text{Form}(\Sigma) \) consisting of the following formulas:

- \( \forall x \cdot x = x \);  
- \( c = c \) for every \( c \in \text{Func}_0(\Sigma) \);  
- \( \forall x_1, y_1, \ldots, x_{n+1}, y_{n+1} \cdot x_1 = y_1 \land \ldots \land x_{n+1} = y_{n+1} \supset f(x_1, \ldots, x_{n+1}) = f(y_1, \ldots, y_{n+1}) \) for every \( f \in \text{Func}_{n+1}(\Sigma) \), for every \( n \in \mathbb{N} \);  
- \( p \supset p \) for every \( p \in \text{Pred}_0(\Sigma) \);  
- \( \forall x_1, y_1, \ldots, x_{n+1}, y_{n+1} \cdot x_1 = y_1 \land \ldots \land x_{n+1} = y_{n+1} \land P(x_1, \ldots, x_{n+1}) \supset P(y_1, \ldots, y_{n+1}) \) for every \( n \in \mathbb{N} \).
We use the name CL here to denote a version of classical logic that has the same logical constants, connectives, and quantifiers as LPQ^\Sigma_F.

### Table 1. Sequent calculus proof system of LPQ^\Sigma_F (\Sigma).

| Rule | Premises | Conclusion |
|------|----------|------------|
| Id   | A, \Gamma \Rightarrow \Delta, A | A, \Gamma \Rightarrow \Delta, A |
| F-L  | F, \Gamma \Rightarrow \Delta | F, \Gamma \Rightarrow \Delta |
| ∧-L  | A_1, A_2, \Gamma \Rightarrow \Delta | A_1 \land A_2, \Gamma \Rightarrow \Delta |
| ∨-L  | A_1 \Rightarrow \Delta, A_2, \Gamma \Rightarrow \Delta | A_1 \lor A_2, \Gamma \Rightarrow \Delta |
| ⊃-L  | \Gamma \Rightarrow \Delta, A_1 \lor A_2, \Gamma \Rightarrow \Delta | \Gamma \Rightarrow \Delta, A_1 \lor A_2 |
| ∀-L  | \forall x \cdot A, \Gamma \Rightarrow \Delta | \forall x \cdot A, \Gamma \Rightarrow \Delta |
| ∃-L  | \exists x \cdot A, \Gamma \Rightarrow \Delta | \exists x \cdot A, \Gamma \Rightarrow \Delta |
| ¬-L  | A, \Gamma \Rightarrow \Delta | \neg A, \Gamma \Rightarrow \Delta |
| ¬∧-L | \neg (A_1 \land A_2), \Gamma \Rightarrow \Delta | \neg (A_1 \land A_2), \Gamma \Rightarrow \Delta |
| ¬∨-L | \neg (A_1 \lor A_2), \Gamma \Rightarrow \Delta | \neg (A_1 \lor A_2), \Gamma \Rightarrow \Delta |
| ¬⊃-L | \neg (A_1 \Rightarrow A_2), \Gamma \Rightarrow \Delta | \neg (A_1 \Rightarrow A_2), \Gamma \Rightarrow \Delta |
| ¬∀-L | \neg \forall x \cdot A, \Gamma \Rightarrow \Delta | \neg \forall x \cdot A, \Gamma \Rightarrow \Delta |
| ¬∃-L | \neg \exists x \cdot A, \Gamma \Rightarrow \Delta | \neg \exists x \cdot A, \Gamma \Rightarrow \Delta |
| =-Refl | t = t, \Gamma \Rightarrow \Delta | t = t, \Gamma \Rightarrow \Delta |
| =-Repl | [x := t]A, \Gamma \Rightarrow \Delta | [x := t]A, \Gamma \Rightarrow \Delta |
| Cut | \Gamma \Rightarrow \Delta, A, \Gamma' \Rightarrow \Delta' | \Gamma, \Gamma' \Rightarrow \Delta, \Delta' |
| ¬-R  | \Gamma \Rightarrow \Delta, \neg A | \Gamma \Rightarrow \Delta, \neg A |
| ∀-R  | \Gamma \Rightarrow \Delta, A_1, \Gamma \Rightarrow \Delta, A_2 | \Gamma \Rightarrow \Delta, A_1 \lor A_2 |
| ∃-R  | \Gamma \Rightarrow \Delta, [x := y]A | \Gamma \Rightarrow \Delta, [x := y]A |
| ¬F-R | \Gamma \Rightarrow \Delta, \neg F | \Gamma \Rightarrow \Delta, \neg F |
| ¬¬-R | \Gamma \Rightarrow \Delta, A | \Gamma \Rightarrow \Delta, A |
| ¬¬¬-R | \Gamma \Rightarrow \Delta, \neg A_1, \neg A_2 | \Gamma \Rightarrow \Delta, \neg (A_1 \land A_2) |
| ¬¬¬¬-R | \Gamma \Rightarrow \Delta, \neg A_1, \neg A_2 | \Gamma \Rightarrow \Delta, \neg (A_1 \lor A_2) |
| ¬¬¬¬¬-R | \Gamma \Rightarrow \Delta, \neg A_1, \neg A_2 | \Gamma \Rightarrow \Delta, \neg (A_1 \lor A_2) |
| ¬¬¬¬¬¬-R | \Gamma \Rightarrow \Delta, \neg (A_1 \lor A_2) | \Gamma \Rightarrow \Delta, \neg (A_1 \lor A_2) |
| ¬¬¬¬¬¬¬¬-R | \Gamma \Rightarrow \Delta, \neg (A_1 \lor A_2) | \Gamma \Rightarrow \Delta, \neg (A_1 \lor A_2) |

† restriction: y is not free in \(\Gamma\), y is not free in \(\Delta\), y is not free in A unless \(x \equiv y\).

Then the sequent \(\Gamma \Rightarrow \Delta\) is provable iff \(\Gamma \Rightarrow \Delta\) is provable without using the inference rules =-Refl and =-Repl. This can easily be proved in the same way as Proposition 7.4 from Takeuti (1975) is proved.

In Middelburg (2020), a proof system of LPQ^\Sigma_F formulated as a sequent-style natural deduction system is given.

### A proof system of CL(\Sigma)

We use the name CL here to denote a version of classical logic that has the same logical constants, connectives, and quantifiers as LPQ^\Sigma_F.
In CL, the same assumptions about symbols are made as in LPQ$^{\Sigma,F}$. The languages of CL$^{(\Sigma)}$ and LPQ$^{\Sigma,F}$ are the same. A sound and complete sequent calculus proof system of CL$^{(\Sigma)}$ can be obtained by adding the following inference rule to the sequent calculus proof system of LPQ$^{\Sigma,F}$:

\[ \Gamma \Rightarrow \Delta, A \quad \Gamma \Rightarrow \Delta, \neg A \]

4. Truth and the logical consequence relation of LPQ$^{\Sigma,F}$

The proof system of LPQ$^{\Sigma,F}$ is based on the logical consequence relation of LPQ$^{\Sigma,F}$ defined in this section: a sequent $\Gamma \Rightarrow \Delta$ is provable iff the logical consequence relation holds between $\Gamma$ and $\Delta$. The logical consequence relation is defined in terms of the valuation of formulas of LPQ$^{\Sigma,F}$. The valuation of formulas of LPQ$^{\Sigma,F}$ is defined relative to a structure and an assignment. First, the notion of a structure and the notion of an assignment are introduced. Next, the valuation of formulas of LPQ$^{\Sigma,F}$ and the logical consequence relation of LPQ$^{\Sigma,F}$ are defined.

Structures

The valuation of terms and formulas from $\text{Form}(\Sigma)$ is defined relative to a structures which consist of a non-empty domain of individuals and an interpretation of every symbol in the signature $\Sigma$ and the equality symbol. The domain of truth values consists of three values: $t$ (true), $f$ (false), and $b$ (both true and false).

A structure $A$ of LPQ$^{\Sigma,F}$ consists of:

- a set $\mathcal{U}^A$, the domain of $A$, such that $\mathcal{U}^A \neq \emptyset$ and $\mathcal{U}^A \cap \{t, f, b\} = \emptyset$;
- for each $c \in \text{Func}_0(\Sigma)$, an element $c^A \in \mathcal{U}^A$;
- for each $n \in \mathbb{N}$, for each $f \in \text{Func}_{n+1}(\Sigma)$, a function $f^A : \mathcal{U}^{A^{n+1}} \rightarrow \mathcal{U}^A$;
- for each $p \in \text{Pred}_0(\Sigma)$, an element $p^A \in \{t, f, b\}$;
- for each $n \in \mathbb{N}$, for each $P \in \text{Pred}_{n+1}(\Sigma)$, a function $P^A : \mathcal{U}^{A^{n+1}} \rightarrow \{t, f, b\}$;
- a function $=^A : \mathcal{U}^{A^2} \rightarrow \{t, f, b\}$ such that, for all $d_1, d_2 \in \mathcal{U}^A$, $=^A(d_1, d_2) \in \{t, b\}$ iff $d_1 = d_2$.

Assignments

An assignment in a structure $A$ of LPQ$^{\Sigma,F}$ assigns elements from $\mathcal{U}^A$ to the variables from $\mathcal{V}ar$. The valuation of terms and formulas from $\text{Form}(\Sigma)$ in $A$ is defined relative to an assignment $\alpha$ in $A$.

Let $A$ be a structure of LPQ$^{\Sigma,F}$. Then an assignment in $A$ is a function $\alpha : \mathcal{V}ar \rightarrow \mathcal{U}^A$. For every assignment $\alpha$ in $A$, variable $x \in \mathcal{V}ar$, and element $d \in \mathcal{U}^A$, we write $\alpha(x \rightarrow d)$ for the assignment $\alpha'$ in $A$ such that $\alpha'(x) = d$ and $\alpha'(y) = \alpha(y)$ if $y \neq x$. 
Table 2. Valuation of terms and formulas of LPQ$^{\Sigma,F}$ ($\Sigma$).

| Term                | Valuation |
|---------------------|-----------|
| $\alpha(x)$         | $\alpha(x)$, |
| $c^A$               | $c^A$    |
| $f^A(t_1, \ldots, t_{n+1})$ | $f^A(t_1, \ldots, t_{n+1})$ |
| $F^A$               | $f^A$    |
| $P^A(t_1, \ldots, t_{n+1})$ | $P^A(t_1, \ldots, t_{n+1})$ |
| $\neg A^A$          | $\neg A^A$ |
| $A_1 \land A_2^A$   | $\begin{cases} t & \text{if } [A_1]^A = t \text{ and } [A_2]^A = t \\ f & \text{if } [A_1]^A = f \text{ or } [A_2]^A = f \\ b & \text{otherwise} \end{cases}$ |
| $A_1 \lor A_2^A$    | $\begin{cases} t & \text{if } [A_1]^A = t \text{ or } [A_2]^A = t \\ f & \text{if } [A_1]^A = f \text{ or } [A_2]^A = f \\ b & \text{otherwise} \end{cases}$ |
| $A_1 \rightarrow A_2^A$ | $\begin{cases} t & \text{if } [A_1]^A = f \text{ or } [A_2]^A = t \\ f & \text{if } [A_1]^A \neq f \text{ or } [A_2]^A = f \\ b & \text{otherwise} \end{cases}$ |
| $\forall x \cdot A^A$ | $\begin{cases} t & \text{if, for all } d \in U^A, [A]^A_{\alpha(x \leftarrow d)} = t \\ f & \text{if, for some } d \in U^A, [A]^A_{\alpha(x \leftarrow d)} = f \\ b & \text{otherwise} \end{cases}$ |
| $\exists x \cdot A^A$ | $\begin{cases} t & \text{if, for some } d \in U^A, [A]^A_{\alpha(x \leftarrow d)} = t \\ f & \text{if, for all } d \in U^A, [A]^A_{\alpha(x \leftarrow d)} = f \\ b & \text{otherwise} \end{cases}$ |

**Valuations and models**

The valuation of the terms from $\text{Term}(\Sigma)$ is given by a function mapping term $t$, structure $A$ and assignment $\alpha$ in $A$ to the element of $U^A$ that is the value of $t$ in $A$ under assignment $\alpha$. Similarly, the valuation of the formulas from $\text{Form}(\Sigma)$ is given by a function mapping formula $A$, structure $A$ and assignment $\alpha$ in $A$ to the element of $\{t, f, b\}$ that is the truth value of $A$ in $A$ under assignment $\alpha$. We write $[t]^A$ and $[A]^A$ for these valuations.

The valuation functions for the terms from $\text{Term}(\Sigma)$ and the formulas from $\text{Form}(\Sigma)$ are inductively defined in Table 2. In this table, $x$ is a meta-variable ranging over all variables from $\text{Var}$, $c$ is a meta-variable ranging over all function symbols from $\text{Func}_0(\Sigma)$, $f$ is a meta-variable ranging over all function symbols from $\text{Func}_{n+1}(\Sigma)$ (where $n$ is understood from the context), $p$ is a meta-variable ranging over all predicate symbols from $\text{Pred}_0(\Sigma)$, $P$ is a meta-variable ranging over all predicate symbols from $\text{Pred}_{n+1}(\Sigma)$ (where $n$ is understood from the context), $t_1, \ldots, t_{n+1}$ are meta-variables ranging over all terms from $\text{Term}(\Sigma)$, and $A$, $A_1$, and $A_2$ are meta-variables ranging over all formulas from $\text{Form}(\Sigma)$.

The following theorem is a decidability result concerning the valuation of formulas in structures with a finite domain.
Theorem 4.1: Let $A$ be a structure of $LPQ^{>^F} (\Sigma)$ such that $\mathcal{U}^A$ is finite, and let $\alpha$ be an assignment in $A$. Then it is decidable whether, for a given $A \in \text{Form}(\Sigma)$, $[A]^A_\alpha \in \{t, b\}$.

Proof: This is easy to prove by induction on the structure of $A$. ■

Let $\Gamma$ be a finite set of formulas from $\text{Form}(\Sigma)$. Then a model of $\Gamma$ is a structure $A$ of $LPQ^{>^F} (\Sigma)$ such that, for all assignments $\alpha$ in $A$, for all $A \in \Gamma$, $[A]^A_\alpha \in \{t, b\}$.

Logical consequence

Let $\Gamma$ and $\Delta$ be finite sets of formulas from $\text{Form}(\Sigma)$. Then $\Delta$ is a logical consequence of $\Gamma$, written $\Gamma \vdash \Delta$, iff for all structures $A$ of $LPQ^{>^F} (\Sigma)$, for all assignments $\alpha$ in $A$, $[A]^A_\alpha = f$ for some $A \in \Gamma$ or $[A']^A_\alpha \in \{t, b\}$ for some $A' \in \Delta$.

The sequent calculus proof system of $LPQ^{>^F} (\Sigma)$ presented in Section 3 is sound and complete with respect to logical consequence as defined above.

Theorem 4.2: Let $\Gamma$ and $\Delta$ be finite sets of formulas from $\text{Form}(\Sigma)$. Then $\Gamma \Rightarrow \Delta$ is provable in the sequent calculus proof system of $LPQ^{>^F} (\Sigma)$ iff $\Gamma \vdash \Delta$.

Proof: In the proof of this theorem use is made of the fact that a sound and complete sequent calculus proof system for $LP^o$, a logic similar to $LPQ^{>^F}$, is available in Picollo (2020). The differences between the two logics are:

- the $\neg$-R rule and the $=\text{Repl}$ rule from the proof system of $LPQ^{>^F}$ differ from the corresponding rules from the proof system of $LP^o$, but in either proof system the rules from the other proof system are both derived inference rules;
- the logical symbols of $LP^o$ include the consistency connective ° and the logical symbols of $LPQ^{>^F}$ do not include this logical symbol, but formulas with it as outermost operator can be defined as abbreviations of formulas in $LPQ^{>^F}$ as follows: $\diamond A$ stands for $(A \supset F) \lor (\neg A \supset F)$;
- the logical symbols of $LPQ^{>^F}$ include $F$, $\supset$, $\land$, and $\forall$ and the logical symbols of $LP^o$ do not include these logical symbols, but formulas with them as outermost operator can be defined as abbreviations of formulas in $LP^o$ as follows: F stands for $A \land \neg A \land \diamond A$ where $A$ is an arbitrary atomic formula, $A_1 \supset A_2$ stands for $(\neg A_1 \land \diamond A_1) \lor A_2$, $A_1 \land A_2$ stands for $\neg(\neg A_1 \lor \neg A_2)$, and $\forall x \cdot A$ stands for $\neg \exists x \cdot \neg A$.

For each formula of one of the two logics which is defined above as an abbreviation of a formula in the other logic, the valuation of the former formula in the former logic is the same as the valuation of the latter formula in the latter logic. Moreover, the first difference mentioned above has no effect on the sequents that can be proved. Therefore, the sequent calculus proof system of $LPQ^{>^F}$ is sound and complete if, for each logical symbol missing in one of the logics, the inference rules for that symbol in the proof system of the other logic become derived inference rules in the proof system of the former logic when the formulas with that symbol as outermost operator are taken for abbreviations of formulas as defined above. It is a routine matter to prove this. ■

A non-standard, indirect proof of soundness and completeness is outlined above. This proof outline clarifies why $LPQ^{>^F}$ is called ‘essentially the same as’ $LP^o$ in Section 1.
Moreover, it follows from this proof outline that the cut elimination property of LP° carries over to LPQ⊃F.

There are two minor differences between LPQ⊃F and LP° that are not mentioned in the proof outline above. The first difference is that a predicate symbol is interpreted in structures of LP° as what is sometimes called a paraconsistent relation (see e.g. Bagai & Sunderraman, 1995) and in structures of LPQ⊃F as what may be called the characteristic function of such a relation. However, this difference is nullified in the valuation of formulas of the form P(t₁, . . . , tn+1). The second difference is that in LP° signatures are restricted to signatures /Σ₁ for which Func₀(/Σ₁) = ∅. By consulting the soundness and completeness proofs in Picollo (2020), it becomes immediately clear that, as expected, this restriction can be removed without effect on the soundness and completeness.

**Abbreviations**

From Section 5 onwards, we use ◦A and A₁ → A₂ as abbreviations for formulas in LPQ⊃F. These abbreviations are defined as follows: ◦A stands for (A ⊃ F) ∨ (¬A ⊃ F) and A₁ → A₂ stands for (A₁ ⊃ A₂) ∧ (¬A₂ ⊃ ¬A₁). It follows from these definitions that:

\[
\llbracket ◦A \rrbracket^A_α = \begin{cases} 
  t & \text{if } \llbracket A \rrbracket^A_α = t \text{ or } \llbracket A \rrbracket^A_α = f \\
  f & \text{otherwise,}
\end{cases}
\]

\[
\llbracket A₁ → A₂ \rrbracket^A_α = \begin{cases} 
  t & \text{if } \llbracket A₁ \rrbracket^A_α = f \text{ or } \llbracket A₂ \rrbracket^A_α = t \\
  b & \text{if } \llbracket A₁ \rrbracket^A_α = b \text{ and } \llbracket A₂ \rrbracket^A_α = b \\
  f & \text{otherwise,}
\end{cases}
\]

5. Relational databases viewed through LPQ⊃F

In this section, relational databases are considered from the perspective of LPQ⊃F. A relational database can be considered from a logical point of view in two different ways: either as a model of a logical theory (the model-theoretic view) or as a logical theory (the proof-theoretic view). Here, the second viewpoint is taken. In the definition of the notion of a relational database, use is made of the notions of a relational language and a relational theory. The latter two notions are defined first. The definitions given in this section are based on those given in Reiter (1984). However, types are ignored for the sake of simplicity (cf. Gallaire et al., 1984; Vardi, 1986).

**Relational languages**

The pair (Σ, Form(Σ)), where Σ is a signature, is called the language of LPQ⊃F(Σ). If Σ satisfies particular conditions, then the language of LPQ⊃F(Σ) is considered a relational language.

Let Σ be a signature. Then the language R = (Σ, Form(Σ)) of LPQ⊃F(Σ) is a relational language iff it satisfies the following conditions:

- Func₀(Σ) is non-empty and finite;
- \( \bigcup \{ Func_{n+1}(Σ) \mid n ∈ \mathbb{N} \} \) is empty;
Below, we will introduce the notion of a relational theory. In the definition of a relational theory, use is made of a number of auxiliary notions. These auxiliary notions are defined first.

Let \( R = (\Sigma, \mathcal{F}orm(\Sigma)) \) be a relational language. Then an atomic fact for \( R \) is a formula from \( \mathcal{F}orm(\Sigma) \) of the form \( P(c_1, \ldots, c_{n+1}) \), where \( P \in \mathcal{P}red_{n+1}(\Sigma) \) and \( c_1, \ldots, c_{n+1} \in \mathcal{F}unc_0(\Sigma) \).

The equality consistency axiom is the formula
\[
\forall x, x' \cdot (x = x').
\]

Let \( R = (\Sigma, \mathcal{F}orm(\Sigma)) \) be a relational language and let \( c_1, \ldots, c_n \) be all members of \( \mathcal{F}unc_0(\Sigma) \). Then the domain closure axiom for \( R \) is the formula
\[
\forall x (x = c_1 \lor \ldots \lor x = c_n)
\]
and the unique name axiom set for \( R \) is the set of formulas
\[
\{ \neg (c_i = c_j) \mid 1 \leq i < j \leq n \}.
\]

Let \( R = (\Sigma, \mathcal{F}orm(\Sigma)) \) be a relational language, let \( \Lambda \subseteq \mathcal{F}orm(\Sigma) \) be a finite set of atomic facts for \( R \), and let \( P \in \mathcal{P}red_{n+1}(\Sigma) \) \((n \in \mathbb{N})\). Suppose that there exist formulas in \( \Lambda \) in which \( P \) occurs and let \( P(c_1^1, \ldots, c_{n+1}^1), \ldots, P(c_1^n, \ldots, c_{n+1}^n) \) be all formulas from \( \Lambda \) in which \( P \) occurs. Then the \( P \)-completion axiom for \( \Lambda \) is the formula
\[
\forall x_1, \ldots, x_{n+1} \cdot P(x_1, \ldots, x_{n+1}) \rightarrow
x_1 = c_1^1 \land \ldots \land x_{n+1} = c_{n+1}^1 \lor \ldots \lor x_1 = c_1^n \land \ldots \land x_{n+1} = c_{n+1}^n.
\]
Suppose that there does not exist a formula in \( \Lambda \) in which \( P \) occurs. Then the \( P \)-completion axiom for \( \Lambda \) is the formula
\[
\forall x_1, \ldots, x_{n+1} \cdot P(x_1, \ldots, x_{n+1}) \rightarrow F.
\]

Let \( R = (\Sigma, \mathcal{F}orm(\Sigma)) \) be a relational language. Then the relational structure axioms for \( R \), written \( RSA(R) \), is the set of all formulas \( A \in \mathcal{F}orm(\Sigma) \) for which one of the following holds:

- \( A \) is the equality consistency axiom;
- \( A \) is the domain closure axiom for \( R \);
- \( A \) is an element of the unique name axiom set for \( R \).

Let \( R = (\Sigma, \mathcal{F}orm(\Sigma)) \) be a relational language, and let \( \Lambda \subseteq \mathcal{F}orm(\Sigma) \) be a finite set of atomic facts for \( R \). Then the relational theory for \( R \) with basis \( \Lambda \), written \( RT(R, \Lambda) \), is the set of all formulas \( A \in \mathcal{F}orm(\Sigma) \) for which one of the following holds:

- \( \mathcal{P}red_0(\Sigma) \) is empty;
- \( \bigcup \{ \mathcal{P}red_{n+1}(\Sigma) \mid n \in \mathbb{N} \} \) is finite.
A set $\Theta \subseteq \text{Form}(\Sigma)$ is called a relational theory for $R$ if $\Theta = RT(R, \Lambda)$ for some finite set $\Lambda \subseteq \text{Form}(\Sigma)$ of atomic facts for $R$. The elements of this unique $\Lambda$ are called the atomic facts of $\Theta$.

The following theorem is a decidability result concerning provability of sequents $\Gamma \Rightarrow A$ where $\Gamma$ includes the relational structure axioms for some relational language.

**Theorem 5.1:** Let $R = (\Sigma, \text{Form}(\Sigma))$ be a relational language, and let $\Gamma$ be a finite subset of $\text{Form}(\Sigma)$ such that $\text{RSA}(\Sigma) \subseteq \Gamma$. Then it is decidable whether, for a given $A \in \text{Form}(\Sigma)$, $\Gamma \Rightarrow A$ is provable.

**Proof:** Because $\text{RSA}(\Sigma) \subseteq \Gamma$, it is sufficient to consider only structures that are models of $\text{RSA}(\Sigma)$. The domains of these structures have the same finite cardinality. Because in addition there are finitely many predicate symbols in $\Sigma$, there exist moreover only finitely many of these structures.

Clearly, it is sufficient to consider only the restrictions of assignments to the set of all variables that occur free in $\Gamma \cup \{A\}$. Because the set of all variables that occur free in $\Gamma \cup \{A\}$ is finite and the domain of the structures to be considered is finite, there exist only finitely many such restrictions and those restrictions are finite.

It follows easily from the above-mentioned finiteness properties and Theorems 4.1 and 4.2 that it is decidable whether, for a formula $A \in \text{Form}(\Sigma)$, $\Gamma \Rightarrow A$ is provable. ■

**Relational databases**

Having defined the notions of an relational language and a relational theory, we are ready to define the notion of a relational database in the setting of LPQ$^{\mathcal{O},\mathcal{F}}$.

A relational database $DB$ is a triple $(R, \Theta, \Xi)$, where:

- $R = (\Sigma, \text{Form}(\Sigma))$ is a relational language;
- $\Theta$ is a relational theory for $R$;
- $\Xi$ is a finite subset of $\text{Form}(\Sigma)$.

$\Theta$ is called the relational theory of $DB$ and $\Xi$ is called the set of integrity constraints of $DB$.

The set $\Xi$ of integrity constraints of a relational database $DB = (R, \Theta, \Xi)$ can be seen as a set of assumptions about the relational theory of the relational database $\Theta$. If the relational theory agrees with these assumptions, then the relational database is called consistent. This is made precise in the following definition.

Let $R = (\Sigma, \text{Form}(\Sigma))$ be a relational language, and let $DB = (R, \Theta, \Xi)$ be a relational database. Then $DB$ is consistent iff, for each $A \in \text{Form}(\Sigma)$ such that $A$ is an atomic fact for $R$ or $A$ is of the form $\neg A'$ where $A'$ is an atomic fact for $R$:

$\Theta \Rightarrow A$ is provable only if $\Theta, \Xi \Rightarrow \circ A$ is provable.
Notice that, if DB is not consistent, \( \Theta, \Xi \Rightarrow A' \) is provable with the sequent calculus proof system of CL(\( \Sigma \)) for all \( A' \in \Form(\Sigma) \). However, the sequent calculus proof system of LPQ\(^{\Sigma,F}(\Sigma) \) rules out such an explosion.

**Models of relational theories**

The models of relational theories for a relational language \( R = (\Sigma, \Form(\Sigma)) \) are structures of LPQ\(^{\Sigma,F}(\Sigma) \) of a special kind.

Let \( R = (\Sigma, \Form(\Sigma)) \) be a relational language. Then a relational structure for \( R \) is a structure \( A \) of LPQ\(^{\Sigma,F}(\Sigma) \) such that:

1. for all \( d_1, d_2 \in U_A, \equiv_A(d_1, d_2) \in \{t, f\} \);
2. for all \( d \in U_A \), there exists a \( c \in \Func_0(\Sigma) \) such that \( \equiv_A(d, c_A) = t \);
3. for all \( c_1, c_2 \in \Func_0(\Sigma) \), \( \equiv_A(c_1^A, c_2^A) = t \) only if \( c_1 \equiv c_2 \).

We have the following lemma.

**Lemma 5.2:** Let \( R = (\Sigma, \Form(\Sigma)) \) be a relational language, and let \( A \) and \( A' \) be relational structures for \( R \). Then there exists a unique bijection \( \beta \) from \( U_A \) to \( U_A' \) such that, for all \( c \in \Func_0(\Sigma) \), \( \beta(c_A) = c_A' \).

**Proof:** This follows immediately from the definition of a relational structure for \( R \). ■

Let \( R = (\Sigma, \Form(\Sigma)) \) be a relational language, and let \( \Theta \) be a relational theory for \( R \). It immediately follows immediately from the definition of a relational structure for \( R \) that each model of RSA(\( R \)) is a relational structure for \( R \). Because RSA(\( R \)) \( \subseteq \Theta \), each model of \( \Theta \) is a relational structure for \( R \) as well. Despite \( \Theta \)'s predicate completion axioms, \( \Theta \) does not have a unique model up to isomorphism. However, identification of \( t \) and \( b \) in the models of \( \Theta \) yields uniqueness up to isomorphism.

Let \( R = (\Sigma, \Form(\Sigma)) \) be a relational language, and let \( A \) be a relational structure for \( R \). Then \( \nabla A \) is the relational structure \( A' \) for \( R \) such that:

1. \( U_{A'} = U_A \);
2. for each \( c \in \Func_0(\Sigma) \), \( c_A' = c_A \);
3. for each \( n \in \mathbb{N} \), for each \( P \in \Pred_{n+1}(\Sigma) \), for each \( d_1, \ldots, d_{n+1} \in U_A' \), \( P_{A'}(d_1, \ldots, d_{n+1}) = \begin{cases} t & \text{if } P_A(d_1, \ldots, d_{n+1}) \in \{t, b\} \\ f & \text{otherwise} \end{cases} \);
4. for each \( d_1, d_2 \in U_A' \), \( \equiv_A'(d_1, d_2) = \equiv_A(d_1, d_2) \).

We have the following lemma.

**Lemma 5.3:** Let \( R = (\Sigma, \Form(\Sigma)) \) be a relational language, let \( \Theta \) be a relational theory for \( R \), and let \( A \) be a relational structure for \( R \). Then \( A \) is a model of \( \Theta \) only if \( \nabla A \) is a model of \( \Theta \).

**Proof:** This follows immediately from the definition of \( \nabla \). ■
Let \( R = (\Sigma, \text{Form}(\Sigma)) \) be a relational language, let \( \Theta \) be a relational theory for \( R \), and let \( A \) be a model of \( \Theta \). Then \( \nabla A \), i.e., \( A \) with \( t \) and \( b \) identified, is in essence a relational database as originally introduced by Codd (1970).

**Theorem 5.4:** Let \( R = (\Sigma, \text{Form}(\Sigma)) \) be a relational language, let \( \Theta \) be a relational theory for \( R \), and let \( A \) be a model of \( \Theta \). Then \( \nabla A \), i.e., \( A \) with \( t \) and \( b \) identified, is in essence a relational database as originally introduced by Codd (1970).

**Proof:** By Lemma 5.3, \( \nabla A \) and \( \nabla A' \) are also models of \( \Theta \). Moreover, because \( RSA(R) \subseteq \Theta \), \( \nabla A \) and \( \nabla A' \) are relational structures for \( R \). It follows, by Lemma 5.2, that there exists a unique bijection \( \beta \) from \( U_{\nabla A} \) to \( U_{\nabla A'} \) such that, for all \( c \in \text{Func}_0(\Sigma) \), \( \beta(c^{\nabla A}) = c^{\nabla A'} \).

Let \( P \in \text{Pred}_{n+1}(\Sigma) \) \( (n \in \mathbb{N}) \). Then, because \( \Theta \) includes the \( P \)-completion axiom for the set of all atomic facts for \( R \) included in \( \Theta \), \( P^{\nabla A} \) and \( P^{\nabla A'} \) are the same up to the above-mentioned bijection. Hence, \( \nabla A \) and \( \nabla A' \) are isomorphic relational structures for \( R \).

\[ \Box \]

**Theorem 5.5:** Let \( R = (\Sigma, \text{Form}(\Sigma)) \) be a relational language, and let \( A \) be a relational structure for \( R \). Then there exists a relational theory \( \Theta \) for \( R \) such that \( A \) is a model of \( \Theta \).

**Proof:** Let \( \Lambda \) be the set of all atomic facts for \( R \) of which \( A \) is a model. Then it is easy to see that, for all \( P \in \bigcup \{ \text{Pred}_{n+1}(\Sigma) \mid n \in \mathbb{N} \} \), \( A \) is a model of the \( P \)-completion axiom for \( \Lambda \). Moreover, it follows immediately from the definition of a relational structure for \( R \) that \( A \) is a model of \( RSA(R) \). Hence, \( A \) is a model of the relational theory \( RT(R, \Lambda) \) of \( R \).

\[ \Box \]

6. **Query answering viewed through \( \text{LPQ}^{\supset,F} \)**

In this section, queries applicable to a relational database and their answers are considered from the perspective of \( \text{LPQ}^{\supset,F} \). As a matter of fact, the queries introduced below are closely related to the relational-calculus-oriented queries originally introduced by Codd (1972).

**Queries**

As to be expected in the current setting, a query applicable to a relational database involves a formula of \( \text{LPQ}^{\supset,F} \).

Let \( R = (\Sigma, \text{Form}(\Sigma)) \) be a relational language. Then a **query for \( R \)** is an expression of the form \( (x_1, \ldots, x_n) \bullet A \), where:

- \( x_1, \ldots, x_n \in \text{Var} \);
- \( A \in \text{Form}(\Sigma) \) and all variables that are free in \( A \) are among \( x_1, \ldots, x_n \).

Let \( DB = (R, \Theta, \Sigma) \) be a relational database. Then a query is **applicable to \( DB \)** iff it is a query for \( R \).

**Answers**

Answering a query with respect to a consistent relational database amounts to looking for closed instances of the formula concerned that are logical consequences of
a relational theory. The main issue concerning query answering is how to deal with inconsistent relational databases.

Let \( R = (\Sigma, \mathcal{F}(\Sigma)) \) be a relational language, let \( DB = (R, \Theta, \Xi) \) be a relational database, and let \((x_1, \ldots, x_n) \cdot A\) be a query that is applicable to \( DB \). Then an answer to \((x_1, \ldots, x_n) \cdot A\) with respect to \( DB \) is a \((c_1, \ldots, c_n) \in \mathcal{F}_{\text{unc}}(\Sigma)^n\) for which \( \Theta \Rightarrow [x_1 := c_1] \ldots [x_n := c_n]A \) is provable.

The above definition of an answer to a query with respect to a database does not take into account the integrity constraints of the database concerned.

### Consistent answers

The definition of a consistent answer given below is based on the following:

- the observation that the formula that corresponds to an answer, being a logical consequence of the relational theory of the database, is also a logical consequence of atomic facts and negations of atomic facts that are logical consequences of that relational theory and the relevant relational structure axioms;
- the idea that in the case of a consistent answer there must be such a set of formulas that does not contain an atomic fact or a negation of an atomic fact that causes the database to be inconsistent.

Let \( R = (\Sigma, \mathcal{F}(\Sigma)) \) be a relational language. Then a semi-atomic fact for \( R \) is a formula from \( \mathcal{F}(\Sigma) \) of the form \( P(c_1, \ldots, c_{n+1}) \) or the form \( \neg P(c_1, \ldots, c_{n+1}) \), where \( P \in \text{Pred}_{n+1}(\Sigma) \) and \( c_1, \ldots, c_{n+1} \in \mathcal{F}_{\text{unc}}(\Sigma) \).

Let \( R = (\Sigma, \mathcal{F}(\Sigma)) \) be a relational language, let \( DB = (R, \Theta, \Xi) \) be a relational database, and let \((x_1, \ldots, x_n) \cdot A\) be a query that is applicable to \( DB \). Then a consistent answer to \((x_1, \ldots, x_n) \cdot A\) with respect to \( DB \) is a \((c_1, \ldots, c_n) \in \mathcal{F}_{\text{unc}}(\Sigma)^n\) for which there exists a \( \Phi \subseteq \{A' | A' \text{ is a semi-atomic fact for } R\} \) such that:

- for all \( A' \in \Phi \), \( \Theta \Rightarrow A' \) is provable and \( \Theta, \Xi \Rightarrow \circ A' \) is provable;
- \( \Phi, RSA(R) \Rightarrow [x_1 := c_1] \ldots [x_n := c_n]A \) is provable.

The above definition of a consistent answer to a query with respect to a database is reminiscent of the definition of a consistent answer to a query with respect to a database given in Bry (1997). It simply accepts that a database is inconsistent and excludes the source or sources of the inconsistency from being used in computing consistent query answers.

### Strongly consistent answers

The definition of a strongly consistent answer given below is not so tolerant of inconsistency and makes use of consistent repairs of the database. The idea is that an answer is strongly consistent if it is an answer with respect to all minimally repaired versions of the original database.

Let \( R = (\Sigma, \mathcal{F}(\Sigma)) \) be a relational language, and let \( \Lambda \subseteq \mathcal{F}(\Sigma) \) be a finite set of atomic facts for \( R \). Then, following Arenas et al. (1999), the binary relation \( \preceq_\Lambda \) on the
set of all finite sets of atomic facts for $R$ is defined by:

$$\Lambda' \leq_{\Lambda} \Lambda'' \iff (\Lambda \setminus \Lambda') \cup (\Lambda' \setminus \Lambda) \subseteq (\Lambda \setminus \Lambda'') \cup (\Lambda'' \setminus \Lambda).$$

Intuitively, $\Lambda' \leq_{\Lambda} \Lambda''$ indicates that the extent to which $\Lambda'$ differs from $\Lambda$ is less than the extent to which $\Lambda''$ differs from $\Lambda$.

Let $R = (\Sigma, \text{Form}(\Sigma))$ be a relational language, let $\Lambda \subseteq \text{Form}(\Sigma)$ be a finite set of atomic facts for $R$, and let $\Xi$ be a finite subset of $\text{Form}(\Sigma)$. Then $\Lambda$ is consistent with $\Xi$ iff for all semi-atomic facts $A$ for $R$, $RT(R, \Lambda) \Rightarrow A$ is provable. The set $\text{Con}(\Xi)$ for the set of all finite sets of atomic facts for $R$ that are consistent with $\Xi$.

Decidability
The following theorem concerns the decidability of being an answer to a query.

**Theorem 6.1:** Let $R = (\Sigma, \text{Form}(\Sigma))$ be a relational language, let $DB = (R, \emptyset, \Xi)$ be a relational database, and let $(x_1, \ldots, x_n) \cdot A$ be a query applicable to $DB$. Then it is decidable whether, for a given $(c_1, \ldots, c_n) \in \text{Func}_0(\Sigma)^n$:

- $(c_1, \ldots, c_n)$ is an answer to $(x_1, \ldots, x_n) \cdot A$ with respect to $DB$;
- $(c_1, \ldots, c_n)$ is a consistent answer to $(x_1, \ldots, x_n) \cdot A$ with respect to $DB$;
- $(c_1, \ldots, c_n)$ is a strongly consistent answer to $(x_1, \ldots, x_n) \cdot A$ with respect to $DB$.

**Proof:** Each of these decidability results follows immediately from Theorem 5.1 and the definition of the kind of answer concerned. \[\square\]

As a corollary of Theorem 6.1, we have that the set of answers to a query, the set of consistent answers to a query, and the set of strongly consistent answers to a query are computable.

**7. Examples of query answering**
For a given database and query applicable to that database, the set of all answers, the set of all consistent answers, and the set of all strongly consistent answers may be different. The examples of query answering given below illustrate this. The examples are
kept extremely simple so that readers that are not initiated in the sequent calculus proof system of LPQ\(^{\ominus,\top}\) can understand the remarks made about the provability of sequents.

**Example 1**
Consider the relational database whose relational language, say \(R\), has constant symbols \(a\) and \(b\) and unary predicate symbols \(P\) and \(Q\), whose relational theory is the relational theory of which \(P(a), P(b),\) and \(Q(a)\) are the atomic facts, and whose only integrity constraint is \(\forall x \cdot \neg(P(x) \land Q(x))\). Moreover, consider the query \(x \cdot P(x)\).

The sets of semi-atomic formulas that are logical consequences of the relational theory but do not cause the database to be inconsistent are \(\{P(b), \neg Q(b)\}\) and all its subsets. We have:

- \(P(b), \neg Q(b), RSA(R) \Rightarrow P(a)\) is not provable;
- \(P(b), \neg Q(b), RSA(R) \Rightarrow P(b)\) is provable.

Hence, the set of consistent answers is \(\{b\}\).

The repairs of \(\{P(a), P(b), Q(a)\}\) are \(\{P(a), P(b)\}\) and \(\{P(b), Q(a)\}\). We have:

- \(RT(R, \{P(b), Q(a)\}) \Rightarrow P(a)\) is not provable;
- \(RT(R, \{P(a), P(b)\}) \Rightarrow P(b)\) is provable;
- \(RT(R, \{P(b), Q(a)\}) \Rightarrow P(b)\) is provable.

Hence, the set of strongly consistent answers is \(\{b\}\).

In this example, the set of all answers differs from the set of all consistent answers and the set of all strongly consistent answers, but the set of all consistent answers and the set of all strongly consistent answers are the same. The repairs of the database are obtained by deletion of atomic facts.

**Example 2**
Consider the relational database whose relational language, say \(R\), has constant symbols \(a, b,\) and \(c\) and unary predicate symbols \(P\) and \(Q\), whose relational theory is the relational theory of which \(P(a), P(b), Q(a),\) and \(Q(c)\) are the atomic facts, and whose only integrity constraint is \(\forall x \cdot P(x) \Rightarrow Q(x)\). Moreover, consider the query \(x \cdot P(x)\).

The set of semi-atomic formulas that are logical consequences of the relational theory but do not cause the database to be inconsistent are \(\{P(a), \neg P(c), [2]Q(a), \neg Q(b), Q(c)\}\) and all its subsets. We have:

- \(P(a), \neg P(c), Q(a), \neg Q(b), Q(c), RSA(R) \Rightarrow P(a)\) is provable;
- \(P(a), \neg P(c), Q(a), \neg Q(b), Q(c), RSA(R) \Rightarrow P(b)\) is not provable.

Hence, the set of consistent answers is \(\{a\}\).
The repairs of \(\{P(a), P(b), Q(a), Q(c)\}\) are \(\{P(a), P(b), Q(a), Q(b), Q(c)\}\) and \(\{P(a), Q(a), Q(c)\}\). We have:

- \(RT(\{P(a), P(b), Q(a), Q(b), Q(c)\}) \Rightarrow P(a)\) is provable;
- \(RT(\{P(a), Q(a), Q(c)\}) \Rightarrow P(a)\) is provable;
- \(RT(\{P(a), Q(a), Q(c)\}) \Rightarrow P(b)\) is not provable.

Hence, the set of strongly consistent answers is \(\{a\}\).

In this example, like in the previous example, the set of all answers differs from the set of all consistent answers and the set of all strongly consistent answers, but the set of all consistent answers and the set of all strongly consistent answers are the same. Unlike in the previous example, one of the repairs of the database is obtained by deletion of an atomic fact and the other is obtained by addition of an atomic fact.

**Example 3**

Consider the relational database whose relational language, say \(R\), has constant symbols \(a, b, c, d, e, f, g\) and ternary predicate symbol \(P\), whose relational theory is the relational theory of which \(P(a, b, c), P(a, c, d), P(a, c, e), \) and \(P(b, f, g)\) are the atomic facts, and whose only integrity constraint is \(∀x, y, z, y', z' \cdot (P(x, y, z) ∧ P(x, y', z')) \Rightarrow [2]y = y'\). Moreover, consider the query \(y \cdot ∃x, z \cdot P(x, y, z)\). Clearly, the set of answers is \(\{b, c, f\}\).

The sets of semi-atomic formulas that are logical consequences of the relational theory but do not cause the database to be inconsistent include \(\{P(a, b, c), P(b, f, g)\}\) and \(\{P(a, c, d), P(a, c, e), P(b, f, g)\}\). We have:

- \(P(a, b, c), P(b, f, g), RSA(R) \Rightarrow ∃x, z \cdot P(x, b, z)\) is provable;
- \(P(a, c, d), P(a, c, e), P(b, f, g), RSA(R) \Rightarrow ∃x, z \cdot P(x, c, z)\) is provable;
- \(P(a, b, c), P(b, f, g), RSA(R) \Rightarrow ∃x, z \cdot P(x, f, z)\) is provable.

Because \(a, d, e, \) and \(g\) are not answers, they cannot be consistent answers. Hence, the set of consistent answers is \(\{b, c, f\}\).

The repairs of \(\{P(a, b, c), P(a, c, d), P(a, c, e), P(b, f, g)\}\) are \(\{P(a, b, c), P(b, f, g)\}\), and \(\{P(a, c, d), P(a, c, e), P(b, f, g)\}\). We have:

- \(RT(\{P(a, c, d), P(a, c, e), P(b, f, g)\}) \Rightarrow P(x, b, z)\) is not provable;
- \(RT(\{P(a, b, c), P(b, f, g)\}) \Rightarrow P(x, c, z)\) is not provable;
- \(RT(\{P(a, c, d), P(a, c, e), P(b, f, g)\}) \Rightarrow P(x, f, z)\) is provable;
- \(RT(\{P(a, b, c), P(b, f, g)\}) \Rightarrow P(x, f, z)\) is provable.

Because \(a, d, e, \) and \(g\) are not answers, they cannot be strongly consistent answers. Hence, the set of strongly consistent answers is \(\{f\}\).

In this example, unlike in the previous two examples, the set of all answers and the set of all consistent answers are the same, but the set of all consistent answers differs from the set of all strongly consistent answers. Like in the first example, the repairs of this database are obtained by deletion of atomic facts.
8. Some remarks about consistent query answering

The definition of a consistent answer to a query with respect to a database given in Section 6 simply accepts that a database is inconsistent and excludes the source or sources of inconsistency from being used in computing consistent query answers. Several considerations underlying this definition are mentioned in the next two paragraphs.

Seeing the extensional nature of the atomic facts of a database and the intensional nature of its integrity constraints, it is natural to consider atomic facts in a database that causes inconsistency with its integrity constraints suspect and consequently not to use them in computing answers to a query with respect to the database. The plain choice not to use the source or sources of inconsistency in computing consistent query answers does not result in additional choices to be made.

The only accepted alternative to deal with an inconsistent database is to base the answers on consistent databases, obtained by deletion and/or addition and/or alteration of atomic facts from the inconsistent database, that differ to a minimal extent from the inconsistent database. This alternative requires rather artificial choices to be made concerning, among other things, the kinds of changes (deletions, additions, alterations) that may be made to the original database and what is taken as the extent to which two databases differ.

The definition of a consistent answer to a query with respect to a database given in Section 6 is reminiscent of the definition of a consistent answer to a query with respect to a database given in Bry (1997). That paper is, to my knowledge, the first paper in which consistent query answering in inconsistent databases is considered. The definition of consistent query answer given in that paper is based on provability in a natural deduction proof system of first-order minimal logic, a paraconsistent logic that is much less close to classical logic than LPQ$^{\supset,F}$. What is missing in Bry (1997) is a semantics with respect to which the presented proof system is sound and complete. This leaves it somewhat unclear how the logical versions of the relevant notions (relational database, query, etc.) defined in that paper are related to their standard version. The Kripke semantics of the propositional fragment of minimal logic that can be found in various publications leaves this unclear as well.

The definition of a strongly consistent answer to a query with respect to a database given in Section 6 is essentially the same as the definition of a consistent answer to a query with respect to a database given in Arenas et al. (1999). It is, to my knowledge, the first definition of a consistent answer based on the idea that an answer is consistent if it is an answer with respect to all minimally repaired versions of the original database. Different views of what is a minimally repaired version of a database are plausible. Views that differ from the original one have been considered in e.g. Lopatenko and Bertossi (2006), Greco and Molinaro (2011), ten Cate et al. (2015), Calautti et al. (2018), and Bertossi (2019).

The view taken in Arenas et al. (1999) is that only deletions and additions of atomic facts may be made to the original database and that the extent to which a repaired version differs from the original database is the symmetric difference of the set of atomic facts in the repaired version and the set of atomic facts in the original database. Most other views differ from this view by considering other allowed kinds of changes. For
example, the case that only deletions of atomic facts may be made and the case that
only additions of atomic facts may be made are considered in ten Cate et al. (2015)
and the case that only alterations of atomic facts may be made is considered in Greco
and Molinaro (2011). The view taken in Lopatenko and Bertossi (2006) differs from the
view taken in Arenas et al. (1999) by taking the cardinality of the above-mentioned
symmetric difference as the extent to which a repaired version differs from the orig-
inal database. It is easy to adapt the definition of a strongly consistent answer given
in Section 6 to the above-mentioned views. The operational view of repairs taken
in Calautti et al. (2018) seems incommensurable with those views. It is unclear whether
the definition of a strongly consistent answer given in Section 6 can be adapted to this
operational view without much difficulty.

In Bry (1997), the definition of a consistent answer is based on the idea that a (usually
large) part of an inconsistent database is consistent and that a consistent answer is
simply an answer with respect to a consistent part of the database. From the viewpoint
taken in Arenas et al. (1999), this means that only one repair is considered. Because
there is in general more than one repair of a database, this is called a shortcoming
in Chomicki (2004). However, the implicit assumption that it is necessary to use the
auxiliary notion of a repair in defining the notion of a consistent answer is nowhere
substantiated.

9. Concluding remarks

This paper builds heavily on the following views related to relational databases and
consistent query answering:

- the proof-theoretic view of Reiter (1984) on what is a relational database, a query
  applicable to a relational database, and an answer to a query with respect to a
  consistent relational database;
- the view of Bry (1997) on what is a consistent answer to a query with respect to
  an inconsistent relational database;
- the view of Arenas et al. (1999) on what is a consistent answer to a query with
  respect to an inconsistent relational database.

The view of Reiter has been combined with the view of Bry as well as with the view
of Arenas et al. and adapted to the setting of the paraconsistent logic LPQ\(\mathcal{D},F\). This
has led to one coherent view on relational databases and consistent query answering
expressed in a setting that is more suitable to this end than classical logic or minimal
logic.

The notion of a relational theory can be generalised by allowing its basis to be
a set of Horn clauses and adapting the completion axioms as sketched in Gallaire
et al. (1984). This generalisation gives rise to a generalisation of the notion of a rela-
tional database that is generally known as the notion of a definite deductive database.
The definitions of an answer, a consistent answer, and a strongly consistent answer
given in this paper are also applicable to this generalisation of the notion of a relational
database. Further generalisation of the notion of an indefinite deductive database is a
different matter.
Note

1. If we replace the inference rule \(\neg-R\) by the inference rule \(\neg-L\) in the sequent calculus proof system of LPQ\(^{\Delta F}(\Sigma)\), then we obtain a sound and complete proof system of the paracomplete analogue of LPQ\(^{\Delta F}\). The propositional part of that logic (K3\(^{\Delta F}\)) is studied in e.g. Middelburg (2021).
