Abstract

We discuss the origin of the difference between the harmonic value of the width of the multiphonon giant resonances and the smaller observed value. Analytical expressions are derived for both the effective width and the average cross-section. The contribution of the Brink-Axel mechanism in resolving the discrepancy is pointed out.

\textsuperscript{*}Supported in part by CNPq and FAPESP.
In a series of publications [1–3], we have advanced the idea that the excitation of the double giant dipole resonances (DGDR) in heavy-ion collisions proceeds in two distinct, incoherent, ways: the usual sequential excitation via the single giant dipole resonance (GDR), usually referred to in the literature as the “harmonic” cross section [4], and the fluctuation excitation that involves the “internal” decay of the GDR into the complicated background states followed by a collective excitation of a GDR on these states, a manifestation of the Brink-Axel mechanism. Of course in a fully microscopic approach to the excitation process, the Brink-Axel effects are also contained. However, the usefulness of the approach of [1,3] is the clear identification of the average cross-section with a “direct” excitation and the fluctuation one with the higher-order “non-direct” contribution. This allows identifying different time scales with the excitation process which makes possible an unambiguous treatment of the eventual decay of the multiphonon states [2]. The question of the “enhancement” of the experimental cross-section with respect to the harmonic value is easily addressed within the average+fluctuation model [1,3]. However, the enhancement problem, especially in $^{136}$Xe still remains not fully resolved. There has also been some discussion in recent years related to the fact that the observed width of the double giant dipole resonance deviates from the harmonic value of twice the single giant resonance width. As we have commented previously, [1] this is a natural result of the incoherent contributions to the cross section, even when the resonances themselves are purely harmonic. In fact, due to the energy dependence of the incoherent contributions to the excitation cross sections, we expect the effective $n$-phonon width to be energy dependent. The purpose of this paper is to derive an analytical expression for the effective energy-dependent width of the $n$-phonon excitation distribution. For this purpose we use multistep distorted wave series in conjunction with statistical averaging that allows us to significantly extend the result of our previous publication [1]. The method enables us to calculate the inclusive $n$-phonon cross-section in closed form and allows us to identify the physical quantity responsible for the cross-section enhancement. This quantity is the product of the damping width of the single phonon resonance times the collision time evaluated at the grazing impact parameter $b_o$.

It is convenient to introduce projection operators: $P$ will stand for the entrance channel, $d_1$ the 1 phonon channel, $q_1$ the corresponding fine structure subspace etc. We use multistep
distorted wave picture. Thus for the excitation of e.g. 2 phonons, one has
\[ \sigma^{(2)} = \left| \langle x_f^{(-)}, f \left| V \left| G_1^{(+)} \right| V \right| x_i^{(+)}(0) \rangle \right|^2. (1) \]

In the above \( V \) stands for the Coulomb interaction responsible for the excitation, \( x^{(+)} \) stands for the appropriate distorted wave and \( G_1^{(+)} \) is the Green’s operator in the subspace \( d_1 + q_1 \). This is given by
\[ G_1^{+} = \begin{pmatrix} g_{d_1d_1} & G_{d_1}^{(+)} v_{d_1q_1} g_{q_1q_1}^{(+)} \\ G_{q_1}^{(+)} & v_{q_1d_1} g_{d_1d_1}^{(+)} \end{pmatrix}, \] (2)

where, \( g_{ij}^{(+)} = (E^{(+)} - H_i - v_{ij}G_j^{+}v_{ji})^{-1} \), \( G_i^{(+)} = (E^{(+)} - H_i)^{-1} \), \( H_i = h_{rel} + h_i \), and \( E^{(+)} = E + i\varepsilon \), with \( h_{rel} \) representing the Hamiltonian of relative motion and \( h_i \) the nuclear Hamiltonian of ion \( i \). The interaction \( v_i \) couples the different subspaces.

The interaction \( V \) connects the ground state to the one-phonon doorway state \( d_1 \). It can also connects a state in \( q_1 \) to a one-phonon Brink-Axel state. Thus the amplitude that enters into the definition of the cross-section \( \sigma^{(2)} \) separates into two pieces
\[ \sigma^{(2)} = \left| \left\langle x_f^{(-)}, 2 \left| V_{d_1d_1} \left( E^{(+)} - H_{d_1} - v_{d_1q_1}G_{q_1}v_{q_1d_1} \right)^{-1}V_{d_10} \right| x_i^{(+)}(0) \right\rangle \right|^2 \]
\[ + \left| \left\langle x_f^{(-)}, 1 \left| V_{d_1q_1} \left( E^{(+)} - H_{d_1} - v_{d_1q_1}G_{q_1}v_{q_1d_1} \right)^{-1} \right| V_{d_10} \left| x_i^{(+)}(0) \right\rangle \right\|^2. \] (3)

The fine structure states \( \{q_1\} \) are quite complicated many particle-many hole configurations. In this respect, a statistical treatment of the second, fluctuation, contribution is called for. Thus we take the energy average of \( \sigma^{(2)} \) to represent the theoretical cross-section to be compared to the data. When performing the energy average, the cross term in Eq. (4) vanishes since it is linear in the assumed random coupling \( v_{q_1d_1} \). Thus \( \bar{\sigma}^{(2)} \) is given, as usual, by the incoherent sum of two terms. The first term is the coherent “harmonic” cross-section. Here the Green’s function \( (E - H_{d_1} - v_{d_1q_1}G_{q_1}v_{q_1d_1})^{-1} \) is replaced by an average over the \( q_1 \) states \( (E - H_{d_1} - v_{d_1q_1}G_{q_1}v_{q_1d_1})^{-1} \). The correction to this approximation involves fluctuations that corresponds to the process \( d_1 \rightarrow q_1 \rightarrow d_1 \), which is negligible. The average \( v_{d_1q_1}G_{q_1}v_{q_1d_1} \) is as usual written as \( \Delta_{d_1} - i\frac{\Gamma_{d_1}}{2} \), which defines the resonance shift \( \Delta_{d_1} \) and width \( \Gamma_{d_1} \) respectively. These two quantities satisfy a dispersion relation. The fluctuation contribution to \( \bar{\sigma}^{(2)} \) involves an average over the \( q_1 \) states.
The average is easily performed if we recall that the $q_1$ Green’s function is a large sum of random contributions. Thus, writing first

$$\frac{G^{(+)}_q}{E^{(+)} - \varepsilon_{q_1} + i\frac{\Gamma_{0q_1}}{2}} = \int \frac{d\vec{k}'}{(2\pi)^3} \sum_{q_1} \frac{|q_1\rangle \langle q_1|}{E^{(+)} - \varepsilon_{q_1} + i\frac{\Gamma_{0q_1}}{2}}$$

where we have employed the scattering eigenstates of $h_{\text{rel}}$, $\{|x^{(+)}_k\rangle\}$, we can reduce the average above into

$$\bar{\sigma}^{(2)}_{fl} = \int \frac{d\vec{k}}{(2\pi)^3} \int \frac{d\vec{k}'}{(2\pi)^3} \langle 0, x^{(+)}_i | V^\dagger g_{d_1}^\dagger | d_1 \rangle \sum_{q_1} \frac{\langle d | v^\dagger | q_1 x^{(+)}_k \rangle \langle q_1 x^{(+)}_k | V^\dagger | x^{(-)}_f \rangle}{E - \varepsilon_{q_1} + i\frac{\Gamma_{0q_1}}{2} - E_k} \cdot \sum_{q_1'} \frac{\langle x^{(-)}_f, 1 | V | q'_t, x^{(+)}_{k'} \rangle \langle q'_t, x^{(+)}_{k'} | v | d_1 \rangle}{E - \varepsilon_{q_1'} + i\frac{\Gamma_{0q_1'}}{2} - E_{k'}}$$

The average over $\{q_1\}$ makes the double $q_1$ sum collapses into a single sum ($q_1 = q'_1$). Further, since there are many $q_1$ states, we replace the $q_1$ sum by an integral $\sum_{q_1} = \int d\varepsilon_{q_1} \rho(\varepsilon_{q_1})$, where $\rho(\varepsilon_{q_1})$ is the density of the $q_1$ states. The $\varepsilon_q$ integral can be easily performed if we assume that the numerator is slowly varying. Only the two $\varepsilon_q$-poles will contribute. Thus

$$\bar{\sigma}^{(2)}_{fl} = \Gamma_{d_1}^\dagger \int \frac{d\vec{k}}{(2\pi)^3} \int \frac{d\vec{k}'}{(2\pi)^3} \langle 0 x^{(+)}_i | V^\dagger g_{d_1}^\dagger | d_1 x^{(+)}_k \rangle \langle 0 (\overline{\varepsilon}_q) x^{(+)}_k | V^\dagger | 1, x^{(-)}_f \rangle \cdot \frac{1}{-\Gamma_{0q_1} + i (E_k - E_{k'})} \langle x^{(-)}_f, 1 | V | 0 (\overline{\varepsilon}_q) x^{(+)}_{k'} \rangle \langle x^{(+)}_{k'} d_1 | v d_1 | 0 x^{(+)}_i \rangle$$

where we have introduced the spreading width of the doorway state $d_1$, defined by

$$\Gamma_{d_1}^\dagger = 2\pi \rho_{q_1} |\langle q_1 | v | d_1 \rangle|^2$$

and also introduced a representative excited intrinsic state $|0 (\overline{\varepsilon}_q)\rangle$, which acts as a ground state for the Brink-Axel phonon excitation.

The energy correlation function $| - \Gamma_{0q_1} + i (\varepsilon_k - \varepsilon_{k'}) |^{-1}$ controls the magnitude of $\sigma_{fl}^{(2)}$. For $\varepsilon_k = \varepsilon_{k'}$, and $\Gamma_{0q_1} \to 0$, the contribution is much smaller than $\sigma_{h}^{(2)}$ since only one $\vec{k}$ integral survive in the former. On the other hand, if $\Gamma_{0q_1}$ is much larger than the range of values of $\varepsilon_k - \varepsilon_{k'}$ which an relevant for the integral, then $\sigma_{fl}^{(2)}$ would be $\frac{\Gamma_{d_1}^\dagger}{\Gamma_{0q_1}}$ times a regular
cross section. However, \( \Gamma_{0q} \) is by definition \( \ll \Gamma_d^4 \), and therefore this last case does not occur. Therefore we may simply say that the correlation function introduces a characteristic time, the “correlation” time, \( \tau_c \) which depends on the bombarding energy. Accordingly we write for \( \sigma_{fl}^{(2)} \) the following

\[
\sigma_{fl}^{(2)} = \Gamma_d^\dagger \tau_c(E) \left| \left\langle x_f^{(-)}, 1 | V | \bar{0} (\varepsilon_{d_1}) \right\rangle \right|^2 \left\langle d_1 | g_d V | 0 x_i^{(+)} \right\rangle^2 ,
\]

where the integrals \( \frac{d^3k}{(2\pi)^3} \int \frac{d^3k'}{(2\pi)^3} \left| x_{k'}^{(+)} \right| \left| x_{k}^{(+)} \right| \left\langle x_{k'}^{(+)} \right| \left\langle x_{k}^{(+)} \right| \) have been set equal to unity since the distorted waves st's \( \{ x_{(+)} \} \) is complete.

Now since \( \left\langle x_f^{(-)}, 1 | V | \bar{0} (\varepsilon_{d_1}) \right\rangle \), contains one Brink-Axel phonons in the final state, where as the corresponding amplitude in the harmonic cross-section, \( \left\langle x_f^{(-)}, 2 | V | 1 \right\rangle \), contains 2, we can make the approximation

\[
\frac{\left\langle x_f^{(-)}, 1 | V | \bar{0} (\varepsilon_{d_1}) \right\rangle}{\left\langle x_f^{(-)}, 2 | V | 1 \right\rangle} \approx \frac{1}{\sqrt{2}}.
\]

Thus we find for \( \sigma_{fl}^{(2)} \), the following reasonable approximate form

\[
\sigma_{fl}^{(2)} = \frac{1}{2} \frac{\Gamma_d^\dagger \tau_c(E)}{\hbar} \sigma_c^{(2)} .
\]

Thus

\[
\sigma^{(2)} = \sigma_c^{(2)} \left( 1 + \frac{1}{2} \frac{\Gamma_d^\dagger \tau_c(E)}{\hbar} \right) .
\]

The second term above gradually becomes insignificant as the bombarding energy increases.

The calculation of the cross-section for higher number of phonons follows a similar procedure. Keeping track of the number of routes that can be followed to reach the final “state”, we have for \( \sigma^{(3)} \)

\[
\sigma^{(3)} = \sigma_c^{(3)} \left( 1 + \frac{2}{3} \frac{\Gamma_d^\dagger \tau_c(E)}{\hbar} + \frac{1}{3} \left( \frac{\Gamma_d^\dagger \tau_c(E)}{\hbar} \right)^2 \right) .
\]

The generalization to \( n \)-phonon is straightforward

\[
\sigma^{(n)} = \sigma_h^{(n)} + \sigma_c^{(n)} \sum_{k=1}^{n} \frac{(n - k)! n - k}{n! n + k} \binom{n}{k} \left( \frac{\Gamma_d^\dagger \tau_c(E)}{\hbar} \right)^k
\]

\[
\equiv \sigma_c^{(n)} + \sum_{k=1}^{n} \sigma_{fi}^{(n)} (k) .
\]
Note that $\sigma_c^{(n)}$ is the cross-section for the excitation of $n$-phonon states that proceeds though $n - 1, n - 2, \ldots$, phonon states which have finite life times (width). In this respect we are generalizing the concept of harmonic cross-section. The consideration of the width of the intermediate states and the fluctuations that result from the decay of these states go hand in hand.

Our analytical formula for the average cross-section is quite reasonable when compared to numerical solution of the evolution equation for the density matrix of the system reported in ref. [3] if the correlation time is identified with the collision time at the grazing impact parameter, $\tau_c = b_0/\gamma v$, Fig. 1. In view of this we are confident in applying our theory to calculate other observables such as the width of the final channel.

Taking a Breit-Wigner form for the spectrum of each of the component in (12) and evaluating this at the peak, we can define an effective width as

$$\frac{\sigma_c^{(n)}}{n\Gamma_{d_1}} + \sum_{k=1}^{n-1} \frac{\sigma_{fl}^{(n)}(k)}{(n-k)\Gamma_{d_1}} = \frac{\sigma^{(n)}}{\Gamma_{eff}^{(n)}},$$

or

$$\Gamma_{eff}^{(n)}(E) = \left(\frac{\sigma_h^{(n)} + \sum_k \sigma_{fl}^{(n)}(k)}{\sigma_c^{(n)} + \sum_{k=1}^{n-1} \frac{n-k}{n-k} \sigma_{fl}^{(n)}(k)}\right) n\Gamma_{d_1} = \frac{1}{1 + \frac{\sum_{k=1}^{n-1} \frac{k}{n-k} \sigma_{fl}^{(n)}(k)}{\sigma^{(n)}}}. \tag{14}$$

Eq. (14) for $\Gamma_{eff}^{(n)}(E)$ shows that the effective width attains the harmonic value $n\Gamma_{d_1}$ at high energies. At low bombarding energy the value can be significantly smaller than $n\Gamma_{d_1}$, owing to the Brink-Axel reduction factor $\left(1 + \frac{\sum_{k=1}^{n-1} \frac{k}{n-k} \sigma_{fl}^{(n)}(k)}{\sigma^{(n)}}\right)^{-1}$. This is demonstrated in Fig. 2. The B-A mechanism thus supplies a correlation between the experimental effective width and the corresponding cross-section. This is an important result which further helps shed light on the excitation mechanism. For two phonons we have $\frac{\sigma_c^{(2)}}{\sigma_c^{(2)}} = 1 + \frac{\Gamma_{eff}^{(2)}}{2\Gamma_1}$. This relation is independent of the system. In figure (3) we exhibit the available data taken from ref. [6]. In presenting the data, we have changed the variable $\frac{\sigma_{exp}^{(2)}}{\sigma_{harm}^{(2)}}$ into $\frac{\sigma_{exp}^{(2)}}{\sigma_c^{(2)}}$, with $\sigma_{harm}^{(2)}$ being the value of $\sigma_c^{(2)}$ when the width of the intermediate one-phonon state is set equal to zero. Although it is claimed that $\Gamma_{eff}^{(2)} = \sqrt{2}\Gamma_1$, our result does not exclude a more subtle connection between $\Gamma_{eff}^{(2)}$ and $\Gamma_1$. 

6
The above discussion suggests defining an effective phonon number \( n_{\text{eff}}^{(E)} \equiv \frac{\sum_{k=1}^{n} \frac{1}{n-k+1} \frac{1}{\sigma^{(n)} f_{l}(k)}}{\sum_{k=1}^{n} \frac{1}{n-k+1} \frac{1}{\sigma^{(n)} f_{l}(k)}} \) which is smaller than \( n \). This gives an immediate qualitative explanation for the enhancement in the cross-section too. Since \( n_{\text{eff}} < n \), the energy \( E_{n_{\text{eff}}} < nE_{1} \). Accordingly, if one were to use damped anharmonic oscillator model with the following sequence of energies, \( 0 \to E_{1} \to 2E_{1} - \frac{\Gamma_{e}}{1+\Gamma_{e}}E_{1} \to 3E_{1} - \frac{\Gamma_{e}+2(\Gamma_{e})^{2}}{1+\Gamma_{e}+(\Gamma_{e})^{2}}E_{1}, \ldots \), one would obtain larger cross-sections \( \sigma^{(2)}; \sigma^{(3)}, \ldots \) when compared to \( \sigma_{c}^{(2)}, \sigma_{c}^{(3)}, \ldots \). In a way, this supplies a simple connection between the direct + fluctuation model and the anharmonic models [7-9]. In Fig. 4 we show the result of a calculation following this line. The multiphonon cross-section calculated for the effective damped anharmonic oscillator (long-dashed line), whose spectrum is given by \( E_{n_{\text{eff}}} = n_{\text{eff}} E_{1} \). The semiclassical coupled channels model [4b] is used to generate this result. The widths of the intermediate states are just the “harmonic” ones \( \Gamma_{n} = n \Gamma_{1} \). Also shown is the cross-section from Ref. [3] (solid line) and the simple undamped harmonic oscillator cross-section also calculated according to [4b] (small dashed line). The results shown are for the system \(^{208}\text{Pb} + ^{208}\text{Pb}\). The agreement of our damped anharmonic oscillator, coupled channels calculation with those of Ref. [3], which is based on the solution of an evolution equation for the excitation probability with loss and gain terms, is excellent.

In conclusion, the direct+fluctuation model (Brink-Axel mechanism) supplies a natural framework to discuss the cross-section enhancement and the width reduction of the multiphonon states. The enhancement factor of the cross-section \( \frac{\sigma^{(n)}}{\sigma_{c}^{(n)}} \) and the width reduction \( \frac{\Gamma_{\text{eff}}}{\Gamma_{c}} \) can be co-related by the effective number of phonons. This concept should be quite useful in future work on multiphonon physics. Further, our results here should also be relevant to other multistep reaction phenomena such as preequilibrium processes [10].
