Abstract

Metal complexes of the type ML$_2$[M=Cu(II), Ni(II), and Co(II), $L_1$=$\alpha,\alpha'$-dipyridyl(dipy.), $L_2$=2-hydroxybenzaldehyde anthranilic acid (HBAA)] have been synthesized by using $\alpha,\alpha'$-dipyridyl(dipy.), 2-hydroxybenzaldehyde anthranilic acid (HBAA) and metal(II) acetate. The resulting mixed ligand metal complexes have been characterized on the basis of elemental analysis, IR-spectra, electronic spectra, magnetic susceptibilities and molar conductance measurements. The antifungal and antibacterial activities of ligands and theremixed complexes have been screened against Aspergillus flavus, Aspergillus fumigatus, Aspergillus niger, Escherichia coli and Staphylococcus aureus.

Key Words: Aspergillus flavus, antifungal activity, Antibacterial activity.

Introduction

When a metal coordinates with only one type of ligand, the complex formed is named simple or binary complex. But when two types of ligands are attached, the formed complex is termed as mixed or ternary complex. In ternary complex when all the co-ordination sites are not satisfied by one type of ligand molecule (Leonard and West., 1992), the second type of ligand replaces the co-coordinated solvent molecule to form more stable mixed ligand complex species (Dagnell and West, 1964).

The formation of ternary complexes is chiefly dependent upon factors such as ionic potential of the metal ion, basicity and denticity of ligand and number of fuse rings in the complex. The stability constant of the mixed ligand metal complexes are much greater than that of binary complexes and that they are increasingly finding larger application in analytical and biological fields.

Heterocyclic dipyridyl(dipy.) containing two heteroatoms and 2-hydroxybenzaldehyde anthranilic acid (HBAA) containing azomethine group finds various applications. They are of extreme importance due to their synthetic flexibility, selectivity and sensitivity towards the metal ions. The hetero donor atoms containing mixed ligand metal complexes increasing importance as antibacterial, antifungal, antiviral, anticancer and also as spray agents in chromatography (Koch and Ackermann, 1976; Farrow and Schieler, 1954; Mathur and Clark, 1973; Mishra and Chaturvedi, 1980; Kumar et al., 1981). In the present work the synthesis, structural studies of mixed ligand metal complexes of Cu(II), Ni(II) and Co(II) with the ligand $L_1$ = $\alpha,\alpha'$-dipyridyl(dipy.) and $L_2$=2-hydroxybenzaldehyde anthranilic acid (HBAA) are described together with their antifungal and antibacterial applications.

Experimental: All the reagents used for synthesis of ligand and their mixed ligand complexes were of AR grade (Clark, 1994; Vogel, 1989).

Ligand ($L_1$)-$\alpha,\alpha'$-dipyridyl(dipy.): It was commercially available and used without further purification.

Synthesis of ligand ($L_2$) 2-hydroxybenzaldehyde anthranilic acid (HBAA): The solution obtained by dissolving 0.05 mol of anthranilic acid in minimum volume of ethanol was mixed with 25 mL of ethanolic solution of 0.05 mol of salicylaldehyde, resulting solution was refluxed on a water bath for 1 h and then allowed to stand over night. Orange-red crystals, so obtained, were filtered and washed with cold water and finally with ethanol. The precipitate was dried and finally recrystallized from ethanol to yield orange-red crystals.

Synthesis of complexes M(dipy.) HBAA: Equimolar solution of $\alpha,\alpha'$-dipyridyl (0.3122g, $2\times10^{-3}$M) in alcohol. HBAA(0.4820 g, 2$\times10^{-5}$M) also in alcohol and equimolar amounts of metal(II) acetate in alcohol were mixed with constant stirring. The p$^{\text{H}}$ of the solution

This paper can be downloaded online at www.ijasbt.org/
was adjusted between 5 and 6. The precipitate obtained was digested over a water bath, filtered and washed with water-acetone mixture (1:1), alcohol, benzene and then with ether. The washed precipitate was dried in vacuum desicator over P₄O₁₀.

**Microbial activities:** All the mixed ligand metal complexes were screened against *Staphylococcus aureus* (gram positive) and *Escherichia coli* (gram negative) bacteria and fungi like *Aspergillus flavus*, *Aspergillus niger*, and *Aspergillus fumigatus* by using agar diffusion method or serial dilution method. An nutrient agar at 40°C was poured in different and well cleaned petri-dishes and allowed to solidify.

The desired fungi/bacteria were inoculated by the loop of platinum wire in the petri-dishes. Filter paper disc were dipped into complex solution (10⁻³ M). Petri-dishes were then kept in BOD incubator observed inhibition of growth of bacteria and fungi after two and seven days, respectively.

The petri-dishes with lowest concentration of ligand/metal chelate were selected in which fungi/bacteria was not detectable. Elemental analyses were obtained from the microanalytical laboratory of CDRI, Lucknow.

### Results and Discussion

The analytical data of mixed ligand metal complexes and their physical properties are given in Table-1. The resulting ligand and their mixed ligand metal complexes are coloured solid and soluble in DMF. The elemental analyses agree with stoichiometry and chemical formula of compound (ML₁L₂).

| Compound           | m.f.     | Elemental analysis | Decom. Temp. (°C) | Colour  | µ_eff | Molar conductance (ohm cm² mol⁻¹) |
|--------------------|----------|--------------------|-------------------|---------|-------|---------------------------------|

In the IR spectra of free ligand HBAA, the stretching bending vibration of –OH (phenolic) group are indicated by 3450 cm⁻¹ and moderate bands at 1365 cm⁻¹ due to intramolecular hydrogen bonded –OH. In the IR spectra of mixed ligand metal complexes the broad band disappear indicating metal to ligand coordination has take place via a deprotonation of penolic –OH group. –OH deformation (acid) show a band at 920 cm⁻¹. A broad band at 3500-3280 cm⁻¹ region in dipy-metal complexes of HBAA is observed. It may be attributed to the stretching frequency of O-H of coordinated water. In these complexes a moderate band at 860-820 and 690-680 cm⁻¹ is also seen rocking and bending vibrations of O-H as observed earlier (Nakamoto, 1967).

This paper can be downloaded online at [www.ijasbt.org/](http://www.ijasbt.org/)
The ν(C=N) vibration of azomethine group in HBAA is indicated by sharp spectral band at 1640 cm⁻¹, when the dipyridyl-metal complexes are formed, this frequency is lowered by 22-25 cm⁻¹. The lowering of frequency may be attributed to coordination of ligand to metal through nitrogen of azomethine group (Busch and Bailar, 1956; Fritz,1964; Taylor and Patton,1974; Daasch and Hanninen,1950). The ν(C=N) vibration of dipy show a moderate spectral band at 1600 cm⁻¹. The frequency undergoes a negative shift of the of 10-75 cm⁻¹ indicating the involvement of pyridine nitrogen in coordination (Clark and Williams, 1965; Gill and Nuttal, 1961).

The presence of bands for out of plane (C-H) bending and deformation (850-620 cm⁻¹) and the ring system (1150-1000 cm⁻¹) has been observed (Colthup, 1950) and the aromatic C=C stretching vibration at (1600 cm⁻¹). In the spectra of complexes M-O and M-N, frequencies can be assigned in the region of 510-480 and 470-305 cm⁻¹, respectively (Ferraro, 1971). The electronic spectra of mixed ligand metal complex of Cu(II) ion in DMF show three bands in the region of 11550, 17460 and 28064 cm⁻¹, which are assigned three spectral bands due to transitions 2B₁g → 2A₁g(v₁), 2B₁g → 2B₂g(v₂) and 2B₁g → 2E₂g(v₃) are expected (Saxena and Shrivastava,1987; Sharma et al.,1987).

This complex can there be assigned distorted octahedral configuration. The magnitude of 10Dq, B and β have been evaluated (Verma et al., 1983). The ratio ν₂/ν₁ is of order of 1.51 as per requirement of distorted octahedral complexes. Mixed ligand metal complex of Ni(II) ion exhibits three bands in the range of 9045, 17305 and 20465 cm⁻¹ corresponding to transitions 1A₂g → 3T₂g(v₁), 3A₂g → 1T₁g(v₂) and 3A₂g → 3T₁g(P)(v₃). The β % value 51.79 % due to partial covalent character in metal-ligand bond. In Ni(dipy.) HBAA.(H₂O)₂ complex, lower value of ν₂/ν₁ (1.90) (Ghosh et al., 2004; Ghosh et al., 2007) suggest some distortion in octahedral symmetry.

In the mixed ligand metal complex of Co(II), three types of spectral bands in the region of 8310, 15425 and 18600 cm⁻¹ corresponding to transitions 4T₁g(F) → 4T₂g(F)(v₁), 4T₁g(F) → 4A₂g(F)(v₂) and 4T₁g(F) → 4T₁g(P)(v₃). Lower values of ν₂/ν₁ around 1.85 for this complex assume its distortion octahedral configuration (Joseph et al., 2006).

A partial covalent character in the metal-ligand bond is deduced β % value which is fall in the range 83-81 (Ghosh et al., 2004; Ghosh et al., 2007). In all the mixed ligand metal complexes values of effective magnetic moment (μₑₑ) higher than the normal value, indicating the monomeric nature of complexes. Complexes of type M(dipy.) HBAA.(H₂O)₂ (M=Cu, Ni or Co) are paramagnetic in nature due to containing unpaired electrons.

The molar conductance values for all the mixed ligand metal complexes in DMF solutions recorded in the range of 6.62-23.58 ohm⁻¹cm²mol⁻¹, indicating non-electrolytic nature of mixed ligand metal complexes. The antimicrobial activities of ligands and mixed ligand metal complexes are given in Table -2. The biocidal activities of mixed ligand metal complexes are sufficiently higher than metal or ligand alone. With increase in the ligand concentration in a complex, the inhibition of growth of rate of fungi and bacteria also increases. So, in case of dipy-complexes the activities depend upon either nature of the ligand or the combined effect of both the metal and ligands present in chelate (Pasha et al., 2007; Raghu and Sanjeeva Reddy,2008a; Raghu and Sanjeeva Reddy,2008b).

### Table 2: Antifungal and antibacterial activities of ligands and their mixed ligand metal complexes

| Ligand/complexes | Fungal growth after 7 days | Bacterial growth after 2 days |
|------------------|---------------------------|-----------------------------|
|                  | A. flavus | A. fumigates | A. niger | S. aureus | E. coli |
| Dipy.            | -        | -            | -        | -        | -        |
| HBAA             | ++       | +++          | +++      | +++      | ++       |
| Cu(dipy)HBAA(H₂O)₂ | -        | -            | -        | -        | -        |
| Ni(dipy)HBAA(H₂O)₂ | +        | +            | -        | -        | -        |
| Co(dipy)HBAA(H₂O)₂ | -        | -            | -        | -        | -        |

+++ = Very high growth. +++ = High growth. ++ = Moderate growth. + = Poor growth. - = No growth
