Abstract
We study tilted perfect fluid cosmological models with a constant equation of state parameter in spatially homogeneous models of Bianchi type $VI_h$ using dynamical systems methods and numerical experimentation, with an emphasis on their future asymptotic evolution. We determine all of the equilibrium points of the type $VI_h$ state space (which correspond to exact self-similar solutions of the Einstein equations, some of which are new), and their stability is investigated. We find that there are vacuum plane-wave solutions that act as future attractors. In the parameter space, a ‘loophole’ is shown to exist in which there are no stable equilibrium points. We then show that a Hopf-bifurcation can occur resulting in a stable closed orbit (which we refer to as the Mussel attractor) corresponding to points both inside the loophole and points just outside the loophole; in the former case the closed curves act as late-time attractors while in the latter case these attracting curves will co-exist with attracting equilibrium points. In the special Bianchi type III case, centre manifold theory is required to determine the future attractors. Comprehensive numerical experiments are carried out to complement and confirm the analytical results presented. We note that the Bianchi type $VI_h$ case is of particular interest in that it contains many different subcases which exhibit many of the different possible future asymptotic behaviours of Bianchi cosmological models.

1. Introduction

In this paper, we shall study tilted perfect fluid cosmological models with a constant equation of state parameter, \(\gamma\), in spatially homogeneous Bianchi models of type VI\(_h\) using the formalism introduced in [1]. We introduce expansion-normalized variables [2], determine the equilibrium points and their stability properties and consequently investigate the future asymptotic behaviour of the models and determine the late-time asymptotic states, using dynamical systems methods and numerical experimentation. In spatially homogeneous cosmological models the universe is foliated into space-like hypersurfaces (defined by the group orbits of the respective model) [2–6]. For these perfect fluid models there are two naturally defined time-like vector fields (i.e., congruences): the unit vector field, \(n^\mu\), normal to the group orbits and hence orthogonal to the surfaces of transitivity (the ‘geometric’ congruence), and the 4-velocity, \(u^\mu\), of the fluid (the ‘matter’ congruence). If \(u^\mu\) is not aligned with \(n^\mu\), the model is called tilted (and non-tilted or orthogonal otherwise) [7]. The geometric congruence is necessarily geodesic, vorticity-free and acceleration-free. The matter congruence, on the other hand, is not necessarily geodesic and can have both vorticity and acceleration.

We shall follow convention and use the kinematical quantities associated with the normal congruence \(n^\mu\) (rather than the fluid flow \(u^\mu\)) of the spatial symmetry surfaces as variables. This avoids the possible singular behaviour experienced by the fluid observers in these models [8–11]. These papers also give the appropriate boost-formulae relating to the kinematic variables and curvatures in the two frames). In principle, it is also necessary to investigate the behaviour in the fluid frame as the asymptotes may differ (which is the case for so-called ‘whimper singularities’ [12]); however, this will not be pursued here (criteria for when this may happen are given in [11]). We will also focus on the dynamical behaviour rather than the physical effects of these models; observational consequences of (tilted) Bianchi models have been studied in, for example, [13–15].

We will assume a perfect-fluid matter source with \(p = (\gamma - 1)\mu\) as an equation of state, where \(\mu\) is the energy density, \(p\) is the pressure, and \(\gamma\) is a constant. Causality then requires \(\gamma\) to be in the interval \(0 \leq \gamma \leq 2\). A positive cosmological constant may also be included in the models. Tilted SH cosmologies with a \(\gamma\)-law perfect fluid source have been studied by a number of authors. In [16], the stability of non-tilted universes with respect to tilt was studied and Table 1 shows previous studies of tilted universes of Bianchi type II–VIII. It has been proven that if the matter obeys the strong energy condition, the positive pressure criteria, the dominant energy condition and a matter regularity condition all Bianchi type IX models recollapse to the future [17–20].

Of the most general ever-expanding Bianchi models (namely VI\(_h\), VII\(_h\) and VIII) only the dynamics of the type VI\(_h\) models remain to be studied. This paper aims to fill this gap in the study of the behaviour of general spatially homogeneous Bianchi models. The behaviour of these models has been shown to be both interesting and surprising. In particular, for the Bianchi type VIII models (and Bianchi models of type VII\(_0\) [31]), the state space is unbounded and consequently, for all non-inflationary perfect fluids, one of the curvature variables grows without bound at late times. It was found that in Bianchi type VIII models [32] with fluids stiffer than dust \((1 < \gamma < 2)\), the fluid will in general tend towards a state of extreme tilt, while for fluids less stiff than dust \((0 < \gamma \leq 1)\) the fluid will in the future be asymptotically non-tilted. Using both dynamical systems theory and a detailed numerical

5 In these papers the physical properties of these models, and particularly the observations and singularity structure in models in which the tilt becomes extreme asymptotically (i.e., \(v^3 \to 1\)) as measured by observers moving with the geometric congruence, was studied.
Table 1. Previous studies of the dynamical behaviour of tilted Bianchi models.

| Bianchi type | Type of tilt | References |
|--------------|--------------|------------|
| II           | General      | [21]       |
| IV           | General      | [1, 22]    |
| V            | Irrotational | [23–26]    |
| VI           | General      | [1, 27]    |
| VI_0         | General      | [28]       |
| VI_h         | 2 fluids     | [29]       |
| VII          | Subset       | [1]        |
| VII_0        | General      | [22]       |
| VII_h        | Irrotational | [1, 30]    |
| VIII         | General      | [31]       |

analysis, the late-time behaviour of tilting perfect fluid Bianchi models of types IV and VII_h was studied, and it was found that the plane waves are the only future attracting equilibrium points for non-inflationary fluids in Bianchi type VII_h models [22]. A tiny region of parameter space (the ‘loophole’) in the Bianchi type IV model was shown to contain a closed orbit which acts as an attractor [1]. From a detailed numerical analysis it was found that at late times the normalized energy density tends to zero and the normalized variables ‘freeze’ into their asymptotic values, and it was then shown that there is an open set of parameter space in the type VII_h models in which solution curves approach a compact surface that is topologically a torus [22].

In this work, we determine all of the equilibrium points of the type VI_h state space. These equilibrium points correspond to exact self-similar solutions of the Einstein equations and play a special role in the general evolution of the system [33]. In particular, the stability of these solutions is determined. Some of these solutions are new (and one is given implicitly). A complete catalogue of self-similar solutions is given and the late-time attractors are classified. A detailed numerical analysis is included, complementing the analytical results. We note that the Bianchi type VI_h case is very complicated, with many cases to consider, and the resulting dynamics include many of the different types of behaviour described in previous work.

This paper is organized as follows. In the following section we present the equations of motion for the tilted Bianchi type VI_h models and discuss the state space and various invariant sets of physical interest. In section 3 we present monotonic functions and give a list of all equilibrium points. Section 4 is devoted to the analysis of the late-time behaviour, and in section 5 we give a synopsis of the numerical analysis done. The final section is devoted to a the discussion of the ramifications of our results.

2. Equations of motion

2.1. The orthonormal frame approach

The line element of a Bianchi cosmology can be written as

\[ ds^2 = -dt^2 + \delta_{ab} \omega^a \omega^b, \]  

where \( t \) is the co-moving cosmological time. The 1-forms \( \omega^a \) are left-invariant 1-forms on the hypersurfaces spanned by the group orbits. They obey the commutator relation

\[ (d\omega^a)_\perp = -\frac{1}{2} C^a_{bc} \omega^b \wedge \omega^c, \quad C^a_{bc} = \epsilon_{bcd} h^{d\alpha} + a_b \delta^a_\epsilon \delta^\epsilon_b - a_c \delta^a_b. \]
where $n^{ab}$ is a symmetric tensor, $a_c = -(1/2) C^a_{\mu c}$ and $\perp$ means projection onto the spatial hypersurfaces. Furthermore, the Jacobi identity implies $n^{bc}a_c = 0$.

Since $n^{ab}$ is a symmetric spatial tensor we can characterize it in terms of its eigenvalues, $(n_1, n_2, n_3)$. We are interested in the Bianchi type VI$_h$ models for which $a_c \neq 0$, and hence, one of the eigenvalues of $n^{ab}$ is necessarily zero: $n_1 = 0$ (say). Moreover, for the Bianchi type VI$_h$ models we have the relation $a_c a^c = h n_2 n_3$, which defines the group parameter $h$.

The geometric (or normal) congruence, $n^\mu$, is given by $n = \partial/\partial t$. It is also useful to define the shear and the Hubble scalar associated with the congruence $n^\mu$:

$$H \equiv \frac{1}{3} n^{\mu;\mu}, \quad \sigma_{\mu \nu} \equiv n_{\mu;\nu} - H h_{\mu \nu},$$

where $h_{\mu \nu}$ is the spatial metric on the hypersurfaces spanned by the group orbits. Furthermore, the Jacobi identity implies $n_{\mu c}c^c$.ac

The evolution equation for $\bar{N}$, which defines the group parameter $h$, is given by $N = \partial/\partial t$. It is also useful to define the shear and the Hubble scalar associated with the congruence $n^\mu$:

$$H \equiv \frac{1}{3} n^{\mu;\mu}, \quad \sigma_{\mu \nu} \equiv n_{\mu;\nu} - H h_{\mu \nu}, \quad (2.3)$$

where $h_{\mu \nu}$ is the spatial metric on the hypersurfaces spanned by the group orbits. The matter variables are chosen to be the energy density, $\rho$, and the tilt-velocity, $v^\mu$, which is defined as the 3-velocity of the fluid with respect to the geometric (or normal) congruence, $n^\mu$. The equations of motion can now be written down in terms of the Hubble scalar, $H$; the shear, $\sigma_{\mu \nu}$; the curvature variables $n^{ab}$ and $a_c$; and the matter variables $\rho$ and $v^\mu$.

In the dynamical systems approach it is common to introduce expansion-normalized variables (we divide the variables with the appropriate powers of $H$). The paper\cite{1} contains all the details regarding the determination of the evolution equations for the tilted cosmological models under consideration. These equations, written in a gauge invariant form, allow one to choose the gauge that is best suited to the application at hand. Here, we shall adopt the $N$-gauge in which the function $N_\tau$ is purely imaginary; this is ensured by the choice $\phi' = \sqrt{3\lambda} \Sigma_\tau$, where $\lambda$ is defined by $\bar{N} = \lambda \, \text{Im}(N_\tau)$. The evolution equation for $N_\tau$ can then be replaced with an evolution equation for $\lambda$, which ensures a closed system of equations. For a qualitative analysis of these models, the $N$-gauge is preferable since the resulting dynamical system is well defined in the Bianchi VI$_h$ case, in particular, $|\lambda| < 1$. The relation between these variables (and their corresponding differential equations) and the models they represent is discussed in more detail in\cite{2}.

In the notation of\cite{1}, the expansion-normalized anisotropy and curvature variables used in this paper are

$$\Sigma_1 = \Sigma_{12} + i \Sigma_{13}, \quad \Sigma_\tau = \Sigma_\tau + i \Sigma_{23}, \quad N = i N.$$

We will also adopt the dimensionless time parameter $\tau$, which is related to the cosmological time $t$ via $\text{d}t/\text{d}\tau = (1/H)$, where $H$ is the Hubble scalar.

Using expansion-normalized variables, the equations of motion in the $N$-gauge are (see\cite{1} for the complete derivation of the equations)

\begin{align}
\Sigma_1' &= (q - 2) \Sigma_\tau + 3(\Sigma_{12}^2 + \Sigma_{13}^2) - 2N^2 + \frac{y \Omega}{2G_+}( - 2v_1^2 + v_2^2 + v_3^2) \\
\Sigma_\tau' &= (q - 2 - 2\sqrt{3}\Sigma_{23}\lambda) \Sigma_\tau + \sqrt{3}(\Sigma_{12}^2 - \Sigma_{13}^2) + 2AN + \frac{\sqrt{3}y \Omega}{2G_+}(v_2^2 - v_3^2) \\
\Sigma_{12}' &= (q - 2 - 3\Sigma_\tau - \sqrt{3}\Sigma_{23}) \Sigma_{12} - \sqrt{3}(\Sigma_{23}^2 + \Sigma_\tau \lambda) \Sigma_{13} + \frac{\sqrt{3}y \Omega}{G_+} v_1 v_2 \\
\Sigma_{13}' &= (q - 2 - 3\Sigma_\tau + \sqrt{3}\Sigma_{23}) \Sigma_{13} - \sqrt{3}(\Sigma_{23}^2 - \Sigma_\tau \lambda) \Sigma_{12} + \frac{\sqrt{3}y \Omega}{G_+} v_1 v_3 \\
\Sigma_{23}' &= (q - 2) \Sigma_{23} - 2\sqrt{3}N^2 \lambda + 2\sqrt{3}\lambda \Sigma_2^2 + 2\sqrt{3}\Sigma_{12}\Sigma_{13} + \frac{\sqrt{3}y \Omega}{G_+} v_2 v_3 \\
N' &= (q + 2\Sigma_\tau + 2\sqrt{3}\Sigma_{23}\lambda) N
\end{align}
Late-time behaviour of the tilted Bianchi type VIa models

\( \lambda' = 2\sqrt{3}\Sigma_{23}(1 - \lambda^2) \)  
\( A' = (q + 2\Sigma_v)A. \)  

The equations for the fluids are

\[
\Omega' = \frac{\Omega}{G_+} \left[ 2q - (3\gamma - 2) + 2\gamma Av_1 + [2q(\gamma - 1) - (2 - \gamma) - \gamma S]\frac{V^2}{V^2} \right] 
\]
\( v'_1 = (T + 2\Sigma_v) v_1 - 2\sqrt{3}\Sigma_{13}v_3 - 2\sqrt{3}\Sigma_{12}v_2 - A (v_2^2 + v_3^2) - \sqrt{3}N (v_2^2 - v_3^2) \)
\( v'_2 = (T - \Sigma_v - \sqrt{3}\Sigma_{-})v_2 - \sqrt{3}(\Sigma_{23} + \Sigma_{-}\lambda)v_3 + \sqrt{3}\lambda N v_1 v_3 + (A + \sqrt{3}N)v_1 v_2 \)
\( v'_3 = (T - \Sigma_v + \sqrt{3}\Sigma_{-})v_3 - \sqrt{3}(\Sigma_{23} - \Sigma_{-}\lambda)v_2 - \sqrt{3}\lambda N v_1 v_2 + (A - \sqrt{3}N)v_1 v_3 \)
\( V' = \frac{V(1 - V^2)}{1 - (\gamma - 1)V^2} [(3\gamma - 4) - 2(\gamma - 1)Av_1 - S], \)

where

\[
q = 2\Sigma^2 + \frac{1}{2} \frac{(3\gamma - 2) + (2 - \gamma)V^2}{1 + (\gamma - 1)V^2} \Omega
\]
\( \Sigma^2 = \Sigma^2_v + \Sigma^2 + \Sigma^2_{12} + \Sigma^2_{13} + \Sigma^2_{23} \)
\( S = \Sigma_{ab}c^a d^b, \quad c^a d^b = 1, \quad v^a = V c^a, \)
\( V^2 = v_1^2 + v_2^2 + v_3^2, \)
\( T = \frac{[(3\gamma - 4) - 2(\gamma - 1)Av_1](1 - V^2) + (2 - \gamma)V^2S}{1 - (\gamma - 1)V^2} \)
\( G_+ = 1 + (\gamma - 1)V^2. \)

These variables are subject to the constraints

\[
1 = \Sigma^2 + A^2 + N^2 + \Omega \quad \text{(2.17)}
\]
\[0 = 2\Sigma_v A + 2\Sigma_- N + \frac{\gamma \Omega v_1}{G_+} \quad \text{(2.18)}
\]
\[0 = -[\Sigma_{12}(N + \sqrt{3}A) + \Sigma_{13}\lambda N] + \frac{\gamma \Omega v_2}{G_+} \quad \text{(2.19)}
\]
\[0 = [\Sigma_{13}(N - \sqrt{3}A) + \Sigma_{12}\lambda N] + \frac{\gamma \Omega v_3}{G_+} \quad \text{(2.20)}
\]
\[0 = A^2 + 3h(1 - \lambda^2)N^2. \quad \text{(2.21)}
\]

The parameter \( \gamma \) will be assumed to be in the interval \( \gamma \in (0, 2) \). The generalized Friedmann equation (2.17) yields an expression which effectively defines the energy density \( \Omega \). We will assume that this energy density is non-negative: \( \Omega \geq 0 \). Therefore, the state vector can thus be considered \( X = [\Sigma_v, \Sigma_-, \Sigma_{12}, \Sigma_{13}, \Sigma_{23}, N, \lambda, A, v_1, v_2, v_3] \) modulo the constraint equations (2.18)–(2.21). Thus the dimension of the physical state space is 7 (for a given value of the parameter \( h \)). Additional details are presented in [1].

The dynamical system is invariant under the following discrete symmetries:

\[
\phi_1 : [\Sigma_v, \Sigma_-, \Sigma_{12}, \Sigma_{13}, \Sigma_{23}, N, \lambda, A, v_1, v_2, v_3] \quad \rightarrow [\Sigma_v, \Sigma_-, \Sigma_{12}, \Sigma_{13}, \Sigma_{23}, -N, \lambda, -A, -v_1, -v_2, -v_3]
\]
These discrete symmetries imply that without loss of generality we can restrict the variables \( A \geq 0 \) and \( N \geq 0 \), since the dynamics in the other regions can be obtained by simply applying one or more of the maps above. The third and fourth symmetries listed imply that one can add additional constraints on the variables \( \Sigma_{12}, \Sigma_{13}, v_2 \) or \( v_3 \); however, in general there is no natural way to restrict any one of the variables, and hence we will not do so here. Note that any equilibrium point in the region \( v_2 > 0 \) has a matching equilibrium point in the region \( v_2 < 0 \).

### 2.2. Invariant sets

In this analysis, we will be concerned with the following invariant sets:

1. \( T(V_{Ih}) \): the general tilted-type \( V_{Ih} \) model: \( |\lambda| < 1 \).
2. \( T_1(V_{Ih}) \): a one-tilted-type \( V_{Ih} \) model: \( |\lambda| < 1 \), \( v_2 = v_3 = \Sigma_{12} = \Sigma_{13} = 0 \).
3. \( T_{1,0}(V_{Ih}) \): a one-tilted diagonal-type \( V_{Ih} \) model: \( v_2 = v_3 = \Sigma_{12} = \Sigma_{13} = \Sigma_{23} = \lambda = 0 \).
4. \( N^\pm(V_{Ih}) \): a class of tilted-type \( V_{Ih} \) models with \( W^0 = 0 \) (see equation (2.23) for definition): \( |\lambda| < 1 \), \( N_{ab}v^a v^b = 0 \) (\( h \neq -1/9 \)).
5. \( T^+(V_{Ih}) \): a two-tilted-type \( V_{Ih} \) model. This is the fixed-point set of \( \phi_1^+ \) and is given by \( v_3 = \Sigma_{13} = \Sigma_{23} = \lambda = 0 \).
6. \( T^-(V_{Ih}) \): a two-tilted-type \( V_{Ih} \) model. This is the fixed-point set of \( \phi_3^- \) and is given by \( v_2 = \Sigma_{12} = \Sigma_{23} = \lambda = 0 \).
7. \( B(V_{Ih}) \): non-tilted-type \( V_{Ih} \): \( |\lambda| < 1 \), \( v_1 = v_2 = v_3 = \Sigma_{12} = \Sigma_{13} = 0 \).
8. \( B_0(V_{Ih}) \): a class of diagonal non-tilted-type \( V_{Ih} \) models \( (n^a = 0) \): \( V = \Sigma_{12} = \Sigma_{13} = \Sigma_{23} = \lambda = 0 \).
9. \( T(II) \): the general-type II model: \( \lambda = \pm 1 \), \( A = 0 \).
10. \( B(I) \): type I: \( N = A = V = 0 \).
11. \( \partial T(I) \): ‘tilted’ vacuum-type I: \( \Omega = N = A = 0 \).

Regarding \( N^\pm(V_{Ih}) \), this invariant set is not a manifold; it is similar to the light-cone in two-dimensional Minkowski space. Therefore, \( N^\pm(V_{Ih}) \setminus T(V_{Ih}) \) consists of four disconnected pieces. By the symmetry \( \phi_2 \), these are actually only two inequivalent pieces. Here, we choose \( N^\pm(V_{Ih}) \) such that

\[
T^+(V_{Ih}) \subset N^+(V_{Ih}), \quad T^-(V_{Ih}) \subset N^-(V_{Ih}).
\]

Since \( N^+(V_{Ih}) \cap N^-(V_{Ih}) = T_1(V_{Ih}) \), both \( N^+(V_{Ih}) \) and \( N^-(V_{Ih}) \) are invariant sets.

We note that the closure of the set \( T(V_{Ih}) \) is given by

\[
\overline{T(V_{Ih})} = T(V_{Ih}) \cup T(II) \cup B(I) \cup \partial T(I).
\]  

Since the boundaries may play an important role in the evolution of the dynamical system we must consider all of the sets in the decomposition (2.22).
Late-time behaviour of the tilted Bianchi type VI$_h$ models

Table 2. The dimensions of the invariant sets for $h \neq -1/9$. The group parameter $h$ is regarded as fixed.

| Dim | 2 | 3 | 4 | 5 | 6 | 7 |
|-----|---|---|---|---|---|---|
| $B_0(VI_h)$ | $T_{1,0}(VI_h)$ | $B(VI_h)$ | $T_1(VI_h)$ | $N^\pm(VI_h)$ | $T(VI_h)$ |

Table 3. The dimensions of the invariant sets for $h = -1/9$ in terms of the number of tilt degrees of freedom. The left-most column indicates the specialization in terms of the $G_2$ cosmologies. Here, HO means hypersurface orthogonal and an asterisk indicates the exceptional case where the models acquire an addition shear degree of freedom.

| Dim | 2 | 3 | 4 | 5 | 6 | 7 |
|-----|---|---|---|---|---|---|
| Gen $G_2$ vacuum* | 0* tilt | 1*, 2 tilt | 2 tilt |
| HO KVF vacuum* | 0* tilt | 1* tilt |

2.3. The case $h = -1/9$

A few comments are in order when $h = -1/9$. Let us consider the constraint equations (2.19) and (2.20) as a linear map

$$L : (\Sigma_{12}, \Sigma_{13}) \mapsto (v_2, v_3)/G_+,$$

where $L$ is considered given in terms of $A, N, \lambda$ and $\Omega$. For $h \neq -1/9$, $\det(L) \neq 0$ and the image of $L$ is two dimensional. However, for $h = -1/9$, $\det(L) = 0$ and the image of $L$ is one dimensional; hence, in this sense the constraint equations are degenerate. This implies that $(v_2, v_3)$ has to be restricted to a one-dimensional submanifold. We will therefore say that the general-type $VI_{-1/9}$ model only allows for two tilt degrees of freedom.

On the same token, this also means that $(v_2, v_3) = 0$ does not necessarily imply that $(\Sigma_{12}, \Sigma_{13})$ is zero. In particular, for the non-tilted models this implies that we may have an additional shear degree of freedom; these models have usually been called the exceptional case and are denoted with an asterisk: $B(VI_{-1/9}^\ast)$.

It is advantageous to redefine $N^\pm(VI_h)$ for $h = -1/9$ because, as can be shown, $N_{ab}u^av^b$ is identically zero for $h = -1/9$. Let us instead define

$$\tilde{D} = [\lambda(\Sigma_{12}^2 + \Sigma_{13}^2) + 2\Sigma_{12}\Sigma_{13}],$$

and define $N^\pm(VI_{-1/9})$ as the set of points where $\tilde{D} = 0$. This is the natural generalization of $N^\pm(VI_h)$ to $h = -1/9$. We also note that for the tilted models, there is an exceptional case of the one-tilted models $T_1(VI_{-1/9})$ which could be denoted as $T_1(VI_{-1/9}^\ast)$. However, $T_1(VI_{-1/9}^\ast) = N^-(VI_{-1/9})$, where $N^-(VI_{-1/9})$ is defined above. Therefore, we keep the notation $N^-(VI_{-1/9})$.

2.4. Fluid vorticity

The various invariant subspaces can also be categorized in terms of the $(H_{\text{fluid}}$ normalized where $H_{\text{fluid}} \equiv (1/3)\mu^{\alpha\mu}$ fluid vorticity, $W^\alpha$. The vorticity of the fluid for the type $VI_h$ models is given by:

$$W_a = \frac{1}{2B} \left( N_{ab}v^b + \varepsilon_{abc}v^b A^c + \frac{1}{1 - V^2} N_{bc}v^b v^c v_a \right), \quad W_0 = -v^a W_a, \quad (2.23)$$
\[ B \equiv \frac{1 - \frac{1}{3}(V^2 + V^2S + 2A_2v^0)}{G - \sqrt{1 - V^2}}. \]

For the invariant sets

1. \( T(\text{VI}_h) \): general vortic-type \( \text{VI}_h \) where all components \( W^a \) can be non-zero.
2. \( N^\pm(\text{VI}_h) \): \( W^0 = W^1 = 0 \).
3. \( T^+_2(\text{VI}_h) \): \( W^0 = W^1 = W^2 = 0 \).
4. \( T^-_2(\text{VI}_h) \): \( W^0 = W^1 = W^3 = 0 \).
5. \( B(\text{VI}_h) \): \( W^0 = W^a = 0 \), non-tilted and non-vortic.

In the special case of \( h = -1/9 \) further components of the vorticity are zero due to the degeneracy of the constraint equations as explained above.

3. Qualitative behaviour

3.1. Monotone functions

There are a number of monotone functions in the state space of interest. For \( 0 < \gamma \leq 6/7 \), there exists a monotonically increasing function \( Z_1 \) defined by

\[ Z_1 \equiv \alpha \Omega^{1-\gamma}, \quad \alpha = \frac{(1 - V^2)^{2(2-\gamma)}}{G V^\gamma}, \quad Z'_1 = [2(1 - \gamma)q + (2 - \gamma) + \gamma S]Z_1. \] (3.1)

To see that this is a monotonically increasing function, note first that \( |S| \leq 2\Sigma [28] \). Then, using the constraint equation (2.17) and \( (1 - \Sigma) \geq (1 - \Sigma^2)/2 \), we can write

\[ 2(1 - \gamma)q + (2 - \gamma) + \gamma S \geq (6 - 7\gamma)\Sigma^2 \]

\[ + 2(1 - \gamma)(|N_x|^2 + A^2) + \frac{\gamma(1 - \gamma)(V^2 + 3)}{G_+} \Omega, \] (3.2)

which is strictly positive for \( \gamma < 6/7 \). Thus for \( 0 < \gamma \leq 6/7 \), \( Z_1 \) is monotonically increasing as claimed.

**Theorem 3.1.** For \( 0 < \gamma \leq 6/7 \), all tilted Bianchi models (with \( \Omega > 0 \), \( V < 1 \)) of solvable type are asymptotically non-tilted at late times.

**Proof.** Use of the monotonic function \( Z_1 \). \( \square \)

In fact, the result that these models are asymptotically non-tilted at late times is true for all \( \gamma < 1 \); this follows from further analysis and numerics, but is not covered by this theorem. This theorem is, in fact, true for all ever-expanding Bianchi models, including ever-expanding class A models.

An immediate result of the above is the following corollary.

**Corollary 3.2** (Cosmic no-hair). For \( \Omega > 0 \), \( V < 1 \), and \( 0 < \gamma < 2/3 \) we have that

\[ \lim_{\tau \to \infty} \Omega = 1, \quad \lim_{\tau \to \infty} V = 0. \]

**Proof.** See [1]. \( \square \)
Let us define

$$D \equiv \bar{N} |v|^2 + \text{Re}(N^*_v v^2),$$

(3.3)

for which

$$D' = (q + 2T + 2Av_1)D.$$  

This implies that $D = 0$ is an invariant subspace and defines $N^+(VI_h)$. Moreover, the following function is a monotone function in $T(VI_h)$, $h \neq -1/9$:

$$Z_2 = \frac{G_s D^2}{(1 - V^2)^{1/2(2 - \gamma)} \Omega},$$

(3.4)

$$Z'_2 = (5\gamma - 6)(3 - 2Av_1)Z_2.$$  

(3.5)

This function is monotonically decreasing for $\gamma < 6/5$ and monotonically increasing for $6/5 < \gamma$.

For a monotone function which is also monotone for $h = -1/9$, we define

$$\tilde{D} = (1 - \lambda^2) \left[ \lambda (\Sigma_{12} + \Sigma_{13}^2) + 2\Sigma_{12} \Sigma_{13} \right] \frac{N^3 G_s^2}{\gamma^2 \Omega^2}.$$  

(3.6)

Using the constraint equations we have $D = -(1 + 9h)\tilde{D}$ so using $\tilde{D}$ instead of $D$ in $Z_2$ gives the same equation of motion.

In the subspaces $T_1(VI_h)$ and $N^-(VI_{-1/9})$, we have the monotone function

$$Z_3 = \frac{v_1^2 \Omega}{A^2 G_s (1 - V^2)^{1/2(2 - \gamma)}},$$

(3.7)

$$Z'_3 = -(2 - \gamma)(3 - 2Av_1)Z_3.$$  

(3.8)

This function is monotonically decreasing in $T_1(VI_h)$.

The monotonic function $Z_3$ immediately implies the following theorem.

**Theorem 3.3** (Future behaviour in $T_1(VI_h)$ and $N^-(VI_{-1/9})$). For $2/3 < \gamma < 2$, $\Omega > 0$, $A > 0$, $v_1^2 < 1$, $v_2 = v_3 = 0$ we have that

$$\text{either } \lim_{t \to \infty} \Omega = 0, \quad \text{or } \lim_{t \to \infty} V = 0.$$  

This implies that all non-vortic-type VI$_h$ universes are either asymptotically vacuum or non-tilted at late times.

In the remains of the section we will present all the equilibrium points including their eigenvalues, and discuss their stability.

### 3.2. Equilibrium points

The Bianchi type VI$_h$ models possess a wealth of equilibrium points. A full catalogue of the equilibrium points has up until now been lacking. Therefore, several of the equilibrium points we list are new. Due to the function $Z_3$, the type VI$_h$ equilibrium points can be divided into four cases, according to whether $D = 0$, $\Omega = 0$ (vacuum), $\gamma = 6/5$, or $V = 1$ (extremely tilted). The equilibrium points in $\partial T(I)$ are all unstable and will not be given here.

6 The list in Apostolopoulos’ paper [34] is incomplete.
3.2.1. B(1): equilibrium points of Bianchi type.

(1) \( T(I) \): \( \Sigma_6 = \Sigma_{12} = \Sigma_{13} = \Sigma_{23} = A = N = V = 0 \) and \( \Omega = 1 \). Here, \( |\lambda| < 1 \) and is an unphysical parameter. This represents the flat Friedman–Lemaître model.

\[
-\frac{3(2 - \gamma)}{2} [\times 5], \quad \frac{3\gamma - 2}{2} [\times 2].
\]

3.2.2. T(II): equilibrium points of Bianchi type II. All of the tilted equilibrium points come in pairs. These represent identical solutions (they differ by a frame rotation); however, since their embeddings in the full state space are inequivalent, two of their eigenvalues are different. All of these equilibrium points have an unstable direction with eigenvalue \(-2\sqrt{3}\Sigma_{23}\) corresponding to the variable \(A\). These equilibrium points are given in [22].

3.2.3. T(VI) : \( D = 0 \) case (\( \Omega > 0, V < 1 \)).

(1) \( C(h) \): Collins perfect fluid solutions, \( h < 0, 2/3 < \gamma < \frac{2(1-h)}{1-3h} \)

\[
\Sigma_{12} = \Sigma_{13} = \Sigma_{23} = \lambda = V = 0, \quad \Sigma_+ = -\frac{1}{4}(3\gamma - 2), \quad \Sigma_- = \frac{\sqrt{-3h}}{4}(3\gamma - 2), \quad N^2 = \frac{3}{16}(3\gamma - 2)(2 - \gamma), \quad A = \sqrt{-3h}N, \quad \Omega = \frac{3}{4}(2 - \gamma) + h(3\gamma - 2).\]

This equilibrium point is in \( B(VI) \).

Eigenvalues:

\[
\lambda_1 + \lambda_2 = \lambda_3 + \lambda_4 = -\frac{3}{2}(2 - \gamma), \quad \lambda_1\lambda_2 > 0, \quad \lambda_3\lambda_4 > 0, \quad \lambda_5 = -\frac{(2 - \gamma)}{\gamma}, \quad \lambda_{6,7} = \pm\frac{1}{2}\gamma[(5\gamma - 6) \pm \sqrt{-h(3\gamma - 2)}].
\]

(2)

\[
\mathcal{R}^+(h) : \left[ \frac{2(3 - \sqrt{-h})}{5 - 3\sqrt{-h}} < \gamma < \frac{3}{2} \right], \quad \frac{-1}{9} \leq h \leq 0
\]

and

\[
\left[ \frac{2(3 - \sqrt{-h})}{5 - 3\sqrt{-h}} < \gamma < \frac{2(1 + 3\sqrt{-h})}{1 + 5\sqrt{-h}} \right], \quad \frac{-1}{4} < h < \frac{-1}{9}, \quad k = \sqrt{-h};
\]

\[
\Sigma_{13} = \Sigma_{23} = \lambda = \nu_3 = 0, \quad \Sigma_+ = -\frac{b - \sqrt{\Delta}}{2a},
\]

where

\[
\Delta = 576k^2\gamma^2(\gamma - 1)(1 + 3k)^2(-36k^2 - 24k - 4 + 120k^2\gamma + 160k\gamma + 40\gamma - 133k^2\gamma^2
\]

\[-182k\gamma^2 - 37\gamma^2 + 49k^2\gamma^3 + 54k\gamma^3 + 9\gamma^3)(6 - 5 \gamma + 3k \gamma - 2k)^2
\]

\[
a = 16(35\gamma - 36)(\gamma - 2) + (-2880\gamma^3 + 12192\gamma^2 - 15936\gamma + 6528)k
\]

\[-(33792\gamma^2 + 8064 - 18432\gamma^3 - 26880\gamma + 36000\gamma^3)k^2
\]

\[-288(\gamma - 1)(15\gamma^3 - 47\gamma^2 + 46 \gamma - 12)k^3 + 432\gamma(3\gamma - 2)(\gamma - 1)k^4
\]

\[
b = 8(\gamma - 2)(35\gamma - 36)(3\gamma - 2) + (-6528 + 11976\gamma^3 + 20256\gamma - 2160\gamma^4
\]

\[-23616\gamma^5)k + (14280\gamma^3 + 25248\gamma - 8064 - 2544\gamma^4
\]
Late-time behaviour of the tilted Bianchi type VI\(_6\) models

\[
- 28800\gamma^3 k^2 + (-10248\gamma^3 + 19392\gamma^2 + 1584\gamma^4 - 14112\gamma + 3456)k^3 \\
+ 144\gamma^2(3\gamma - 2)(\gamma - 1)k^4,
\]

\[
\Sigma_{\gamma} = \frac{(3\gamma - 2) + 4\Sigma_{\gamma} + k(1 - 2\Sigma_{\gamma})(5\gamma - 6)}{2\sqrt{3}\gamma k},
\]

\[
\Sigma_{12} = \frac{(1 - 2\Sigma_{\gamma})(C_0 + C_1\Sigma_{\gamma})}{6k\gamma^2(3\gamma - 2)k - (5\gamma - 6)},
\]

where

\[
\begin{align*}
C_0 &= (2 - \gamma)(5\gamma - 4)(3\gamma - 2) + 2(-19\gamma^3 + 60\gamma^2 - 64\gamma + 24)k - \gamma(3\gamma - 2)(5\gamma - 6)k^2 \\
C_1 &= 4(2 - \gamma)(5\gamma - 4) + 8(5\gamma^3 - 24\gamma^2 + 32\gamma - 12)k - 4\gamma(3\gamma - 2)(2\gamma - 3)k^2 \\
N^2 &= \frac{[(3\gamma - 2)(4\Sigma_{\gamma} + 1)(5\gamma - 6) + 3k(7\gamma - 6)(2 - \gamma)]}{12k^2\gamma^2[(3\gamma - 2)k - (5\gamma - 6)]}, \\
A &= \sqrt{3}kN.
\end{align*}
\]

The expressions for \(\Omega\) and \(V^2\) are given in the appendix, equations (A.4) and (A.5).

This equilibrium point lies in \(T^2(\text{VI}_h)\).

\[
\begin{align*}
\text{Re}(\lambda_{1,2,3,4}) &< 0, & \lambda_5 + \lambda_6 &= -2(1 + \Sigma_{\gamma}), \\
\lambda_5\lambda_6 &> 0, & \lambda_7 &= \frac{1}{2}(5\gamma - 6)(3 - 2\Sigma_{\gamma}).
\end{align*}
\]

This equilibrium point is stable in \(N^2(\text{VI}_h)\), but always has one unstable eigenvalue in \(T(\text{VI}_h)\).

(3)

\[
R^- (h) : \left[ \frac{2(3 + \sqrt{-h})}{5 + 3\sqrt{-h}} < \gamma < \frac{3}{2}, \frac{-1}{9} \leq h \leq 0 \right]
\]

and

\[
\left[ 1 < \gamma < \frac{2(3 + \sqrt{-h})}{5 + 3\sqrt{-h}}, -1 < h < \frac{-1}{9} \right], \quad k = -\sqrt{-h}.
\]

This point is given via the expressions for \(R^+(h)\) above with \(k < 0\) but \(\Sigma_{\gamma} = \frac{b\sqrt{\gamma}}{2a}\) and using the symmetries \(\phi_2, \phi_3\) and \(\phi_4\) (thus interchanging \(\Sigma_{12}\) and \(\Sigma_{13}\), and \(v_2\) and \(v_3\) so that \(\Sigma_{12} = v_2 = 0\).

This equilibrium point lies in \(T_2^- (\text{VI}_h)\).

Eigenvales:

\[
\begin{align*}
\text{Re}(\lambda_{1,2,3}) &< 0, & \text{Re}(\lambda_4) &= \begin{cases} 
< 0, & -1/9 < h \leq 0 \\
> 0, & -1 < h < -1/9,
\end{cases} \\
\lambda_5 + \lambda_6 &= -2(1 + \Sigma_{\gamma}), \quad \lambda_5\lambda_6 > 0, \quad \lambda_7 = \frac{1}{2}(5\gamma - 6)(3 - 2\Sigma_{\gamma}).
\end{align*}
\]

This equilibrium point is stable in \(N^- (\text{VI}_h)\) for \(-1/9 < h \leq 0\), is stable in \(T(\text{VI}_h)\) for \(\frac{2(3 + \sqrt{-h})}{5 + 3\sqrt{-h}} < \gamma < \frac{6}{5}, -\frac{1}{9} \leq h \leq 0\) and has one unstable eigenvalue otherwise. The eigenvalue \(\lambda_4\) corresponds to a direction in \(T^- (\text{VI}_h)\), while \(\lambda_7\) corresponds to the quantity \(D\), defined earlier.
3.2.4. \( T(VI_h) \): vacuum case (\( \Omega = 0 \)). All of these equilibrium points are plane wave solutions and exist for \( 0 < \gamma < 2 \), \( h < 0 \). Moreover, they all have \( D = 0 \), and

\[
\begin{align*}
\Omega &= \Sigma_{12} = \Sigma_{13} = \Sigma_{23} = 0, \\
\Sigma_- &= N = \sqrt{-\Sigma_+ (1 + \Sigma_+)} , \\
A &= (1 + \Sigma_+), \quad -1 < \Sigma_+ < 0, \quad |\lambda| < 1.
\end{align*}
\]

The group parameter is given by \( 3h \Sigma_+ (1 - \lambda^2) = (1 + \Sigma_+) \). It is also advantageous to introduce \( r \equiv \sqrt{1 - \lambda^2} \) and the parameter \( K^2 = -1/h \) (\( K \) can have either sign). This implies that we can write

\[
\Sigma_+ = -\frac{K^2}{K^2 + 3r^2}, \quad 0 < r \leq 1.
\]

We will also define \( \rho \) by

\[
\rho = v_2^2 + v_3^2.
\]

For all equilibrium points with \( \Omega = 0 \), three of the eigenvalues are always

\[
\lambda_1 = 0, \quad \lambda_{2,3} = -2[(1 + \Sigma_+) \pm 2i\sqrt{3} \lambda N].
\]

The equilibrium points are then determined by the tilt velocities.

1. \( \mathcal{L}(h) : v_1 = v_2 = v_3 = 0 \). These represent ‘non-tilted’ plane waves and lie in \( B(VI_h) \).

Eigenvalues:

\[
\begin{align*}
\lambda_4 &= -\frac{3}{K^2 + 3r^2}[\gamma(K^2 + 3r^2) - 2(K^2 + r^2)], \\
\lambda_5 &= -\frac{3}{K^2 + 3r^2}[2(K^2 + 2r^2) - \gamma(K^2 + 3r^2)], \\
\lambda_{6,7} &= -\frac{3}{K^2 + 3r^2}[(K^2 + 4r^2 \pm |K|r^2) - \gamma(K^2 + 3r^2)].
\end{align*}
\]

2. \( \mathcal{L}(h) : v_1 = \frac{\gamma(K^2 + 3r^2) - 2(K^2 + 2r^2)}{2(\gamma - 1)} , v_2 = v_3 = 0, \frac{2(K^2 + 3r^2)}{K^2 + 3r^2} < \gamma < 2 \). These represent ‘intermediately tilted’ plane waves and lie in \( T_1(VI_h) \).

Eigenvalues:

\[
\begin{align*}
\lambda_4 &= -\frac{3(K^2 + r^2)(2 - \gamma)}{(K^2 + 3r^2)(\gamma - 1)}, \\
\lambda_5 &= -\frac{3(K^2 + r^2)[(K^2 + 5r^2)\gamma - 2(K^2 + 3r^2)][(K^2 + 3r^2)\gamma - 2(K^2 + 2r^2)]}{(K^2 + 3r^2)(\gamma - 1)(K^2 + 4K^2r^2 + 5r^3)} \\
\lambda_{6,7} &= -\frac{3(K^2 + r^2)[3\gamma - 4 \pm |K| (2 - \gamma)]}{2(K^2 + 3r^2)(\gamma - 1)}.
\end{align*}
\]

3. \( \mathcal{L}_h(h) : v_1 = \pm 1, v_2 = v_3 = 0 \). These represent ‘extremely tilted’ plane waves and lie in \( T_1(VI_h) \).

Eigenvalues:

\[
\begin{align*}
\mathcal{L}_+(h) : & \quad \lambda_4 = 0, \quad \lambda_5 = 2\lambda_6 = 2\lambda_7 = \frac{6(K^2 + r^2)}{(K^2 + 3r^2)} \\
\mathcal{L}_-(h) : & \quad \lambda_4 = -\frac{12r^2}{K^2 + 3r^2}, \quad \lambda_5 = -\frac{6[(K^2 + 5r^2)\gamma - 2(K^2 + 3r^2)]}{(K^2 + 3r^2)(2 - \gamma)}, \\
\lambda_{6,7} &= -\frac{3}{K^2 + 3r^2}(r^2 \pm 2|K|r^2 - K^2).
\end{align*}
\]
Late-time behaviour of the tilted Bianchi type $VI_3$ models

(4) $\tilde{F}^+(h)$. Here $K > 0$ and

$$v_1 = -\frac{\gamma(K^2 + 3r^2) - (K^2 + Kr^2 + 4r^2)}{r^2(3 - 2\gamma + K)}$$
$$v_2^2 - v_3^2 = \text{sign}(K)\rho r$$
$$\rho = \frac{(K^2 + r^2)[2(2 + K) - (3 + K)\gamma][\gamma(K^2 + 3r^2) - (K^2 + Kr^2 + 4r^2)]}{r^4(1 + K)(3 - 2\gamma + K)^2},$$

where

$$\frac{2(K + 2)}{K + 3} \leq \gamma \leq \frac{K^2 + (4 + K)r^2}{K^2 + 3r^2},$$

for $0 < K < r^2$,

$$\frac{K^2 + (4 + K)r^2}{K^2 + 3r^2} \leq \gamma \leq \frac{2(K + 2)}{K + 3},$$

for $r^2 \leq K < r(r + \sqrt{r^2 + 1})$,

$$\frac{K^2 + (4 + K)r^2}{K^2 + 3r^2} \leq \gamma \leq \frac{K^2 + 3r^2}{K^2 + (2 - K)r^2},$$

for $r(r + \sqrt{r^2 + 1}) \leq K$.

These represent ‘intermediately tilted’ plane waves and lie in $N^+(VI_h)$ (for $\lambda = 0$ they lie in $T^*_2(VI_h)$).

Eigenvalues:

$$\lambda_4 = -\frac{3(K^2 + r^2)((5 + K)\gamma - 2(3 + K))}{(K^2 + 3r^2)(3 - 2\gamma + K)},$$
$$\lambda_5 = 2\sqrt{3}(1 - v_1)\text{sign}(K)Nr,$$

$$\lambda_6 + \lambda_7 = -\frac{3(K^2 + r^2)F(K, r, \gamma)}{(3 - 2\gamma + K)(K^2 + 3r^2)G(K, r, \gamma)},$$

$$\lambda_6\lambda_7 = \frac{18(K^2 + r^2)^2[2(2 + K) - (3 + K)\gamma]}{(K^2 + 3r^2)^2(3 - 2\gamma + K)G(K, r, \gamma)},$$

$$\lambda_6\lambda_7 \leq \frac{2(K + 2)}{K + 3},$$

for $K \leq r(r - \sqrt{r^2 + 1})$,

$$\frac{K^2 + (4 + K)r^2}{K^2 + 3r^2} \leq \gamma \leq \frac{2(K + 2)}{K + 3},$$

for $r(r - \sqrt{r^2 + 1}) \leq K < 0$.

These represent ‘intermediately tilted’ plane waves and lie in $N^-(VI_h)$ (for $\lambda = 0$ they lie in $T^*_2(VI_h)$).

Eigenvalues: as for $\tilde{F}^+(h)$ but with $K < 0$.

(5) $\tilde{F}^-(h)$. These are given by the same expressions as for $\tilde{F}^+(h)$ but with $K < 0$. The range of $\gamma$ is as follows:

$$\frac{K^2 + (4 + K)r^2}{K^2 + 3r^2} \leq \gamma \leq \frac{K^2 + 3r^2}{K^2 + (2 - K)r^2},$$

for $K \leq r(r + \sqrt{r^2 + 1})$,

$$\frac{K^2 + (4 + K)r^2}{K^2 + 3r^2} \leq \gamma \leq \frac{2(K + 2)}{K + 3},$$

for $r(r + \sqrt{r^2 + 1}) \leq K < 0$.

(6) $\tilde{F}^+_p(h)$. Here $K > r(r + \sqrt{r^2 + 1})$ and

$$v_1 = -\frac{r^2(1 + K)}{K(K - r^2)},$$
$$v_2^2 - v_3^2 = \text{sign}(K)\rho r$$
$$\rho = 1 - v_1^2 = \frac{(K^2 + r^2)(K^2 - 2r^2K - r^2)}{K^2(K - r^2)^2}. $$
These represent ‘extremely tilted’ plane waves and lie in $N^*(V_l,h)$ (for $\lambda = 0$ they lie in $T^*_2(V_l,h)$).

Eigenvalues:

$$\lambda_4 = \frac{3(K^2 + r^2)[K - r(r + \sqrt{r^2 + 3})][K - r(r - \sqrt{r^2 + 3})]}{K(K - r^2)(K^2 + 3r^2)},$$

$$\lambda_5 = 2\sqrt{3}(1 - v_1)\text{sign}(K)Nr,$$

$$\lambda_6 + \lambda_7 = -\frac{3(K^2 + r^2)[(5r^2 + K^2)y - 4r^2(2 + K)]}{K(K - r^2)(K^2 + 3r^2)(2 - y)},$$

$$\lambda_6\lambda_7 = \frac{18(K^2 + r^2)^2(K^2 - 2Kr^2 - r^2)(K^2 + 2r^2 - K^2)r^2}{K^2(K - r^2)^2(K^2 + 3r^2)^2(2 - y)}.$$

(7) $\tilde{E}_p^\gamma(h)$. These are given by the same expressions as for $\tilde{E}_p(h)$ but with $K < r - \sqrt{r^2 + 1}$.

These represent ‘extremely tilted’ plane waves and lie in $N^-(V_l,h)$ (for $\lambda = 0$ they lie in $T^*_2(V_l,h)$).

Eigenvalues: as for $\tilde{E}_p(h)$ but with $K < r - \sqrt{r^2 + 1}$.

3.2.5. $T(V_l,h) : \gamma = 6/5$ case ($\Omega > 0$, $V < 1$, $D \neq 0$).

(1) $B(h), -1/9 < h < 0, \gamma = 6/5, k = \sqrt{-h}$.

$$\Sigma_{11} = 0, \quad A = \sqrt{3}krN, \quad r = \sqrt{1 - \lambda^2},$$

$$v_1 = \frac{2}{3}A, \quad \Sigma_{-} = \frac{2}{3}NA, \quad \Sigma_{+} = -\frac{2}{3}(1 - A^2),$$

$$\Omega = \frac{5 + V^2}{15} - 3(1 - A^2) - N^2, \quad (\Sigma_{12}, \Sigma_{13}) = \Sigma_\perp(\cos \psi, \sin \psi),$$

$$(v_2, v_1) = v_\perp(\cos \phi, \sin \phi),$$

$$\Sigma_{\perp} = -\frac{1}{5}V^2(1 - A^2) + \frac{1}{3}(2 + V^2)N^2 - \frac{4}{25}(1 - A^2)^2 - \frac{4}{9}N^2A^2,$$

$$v_\perp^2 = V^2 - \frac{4}{9}A^2,$$

and $\psi$ is given by $-\pi/2 < \psi < 0$ and

$$\cos(2\psi) = kr\frac{-12MN^2 + 16MN^4k^2r^2 - 15M^2v_\perp^2 + 15\Sigma_{\perp}^2N^2r^2(9k^2 - 1)}{5\Sigma_{\perp}^2[2M + N^2r^2(1 - 9k^2)]},$$

where $M = \frac{2}{5}(1 - A^2) - 2N^2$.

The tilt velocity $V$ and the angle $\phi$ are given in terms of $(k, N, \lambda)$ (see the appendix, equations (A.1) and (A.2)). The variable $\lambda$ is determined implicitly by a sixth-order polynomial equation $P(k, N, \lambda) = 0$ in $\lambda^2$, where $N$ and $k$ appear as parameters. This polynomial is also given in the appendix, equation (A.3). There is a unique solution in terms of $\lambda$, up to symmetries, as long as the range of the parameters $k$ and $N$ are as follows:

$$0 \leq k < 1, \quad N^2_{\text{lower}} \leq N^2 \leq \frac{12}{25 - 9k^2},$$

where

$$N^2_{\text{lower}} = \frac{65 - 60k + 27k^2 - 5(1 - 3k)\sqrt{9k^2 + 6k + 49}}{(5 + 3k)(-18k^3 + 15k^2 - 20k + 25)}.$$

If and only if the parameters $k$ and $N$ obey the bounds above, there exists an equilibrium point for the system. Hence, for every $-1/9 < h \leq 0$, $\gamma = 6/5$, there exists a one-parameter family of equilibrium points, parametrized by $N$. In figure 1 we have plotted the surface $P(k, N, \lambda) = 0$ defining the solutions $B(h)$.

This family of non-isolated equilibrium points connects $R^{-}(h)$ for $-1/9 < h \leq 0$ and $E_{2}(h)$ at $\gamma = 6/5$.

Eigenvalues: numerical calculation of the eigenvalues shows

$$\lambda_1 = 0, \quad \text{Re}(\lambda_{2,3,4,5,6,7}) < 0.$$  

Hence, this line of equilibria is stable in $T(VI_{h})$ whenever it exists.

**3.2.6.** $T(VI_{h})$: extremely tilted case ($\Omega > 0$)

(1) $E_{1}^{+}(h), -1/9 < h \leq 0$ and $0 < \gamma < 2, k = \sqrt{-h}$:

$$\Sigma_{13} = \Sigma_{23} = v_3 = 0,$$

$$\Sigma_{-} = \frac{\sqrt{3}(21k^2 - 10k - 3)}{12(1 + k)(3k - 2)},$$

$$N = \frac{1 - k}{2(2 - 3k)(k + 1)^2},$$

$$v_1 = -\frac{(3 - 5k)^2}{6(2 - 3k)(1 - k)},$$

and

$$\Omega = \frac{(1 - 9k^2)(1 - k)}{2(2 - 3k)(1 + k)^2}.$$  

This equilibrium point lies in $T_{2}^{+}(VI_{h})$.  

---

Figure 1. The equilibrium points $B(h)$: Here the surface $P(k, N, \lambda) = 0$ is plotted in $(k, N, r)$ space (recall that $r = \sqrt{1 - \lambda^2}$).
Eigenvalues:

\[ \lambda_1 = -\frac{(3 - 7k^2)}{(2 - k - 3k^2)}, \]

\[ \lambda_{2,3} = \lambda_{4,5} = -\frac{3(1 - k)^2}{4(2 - 3k)(1 + k)}, \]

\[ \lambda_6 = -\frac{(3 - 7k^2)(2g - 3)}{(2 - 3k)(1 + k)(2 - g)}, \]

\[ \lambda_7 = \frac{3(3 - 7k^2)}{2(2 - k - 3k^2)}. \]

This equilibrium point is stable in \( N^*(V_{1h}) \) for \( g > 3/2 \), and always unstable in \( T(V_{1h}) \).

(2) \( E_1^*(h) \), \(-1/9 < h \leq 0 \) and \( 0 < g < 2 \), \( k = -\sqrt{\frac{1}{g}} \):

This point is given via the expressions for \( E_1^*(h) \) above with \( k < 0 \) and using the symmetries \( \phi_2, \phi_1 \) and \( \phi_4 \) (thus interchanging \( \Sigma_{12} \) and \( \Sigma_{13} \), and \( v_2 \) and \( v_3 \) so that \( \Sigma_{12} = v_3 = 0 \)).

This equilibrium point lies in \( T_1^*(V_{1h}) \).

Eigenvalues: expressions same as for \( E_1^*(h) \) but with \( k < 0 \).

Stable in \( N^*(V_{1h}) \) for \( g > 3/2 \), always unstable in \( T(V_{1h}) \).

(3) \( E_2(h) \), \(-1/9 < h \leq 0 \) and \( 0 < g < 2 \):

\[ \Sigma_{23} = \lambda = 0, \quad \Sigma_\ast = -\frac{2(5 + 9h)}{25 + 9h}, \quad N = \sqrt{\frac{12}{25 + 9h}}, \]

\[ \Sigma_\ast = \frac{2}{3} \sqrt{3hN^2}, \quad A = -\sqrt{3hN}, \quad v_1 = \frac{2}{3} \sqrt{3hN}, \]

\[ \Omega = \frac{6(1 + 9h)}{25 + 9h}, \quad (\Sigma_{12}, \Sigma_{13}) = \Sigma_\perp (\cos \psi, \sin \psi), \]

\[ (v_2, v_3) = v_\perp (\cos \phi, \sin \phi) \]

where

\[ \Sigma_\perp^2 = \frac{15(1 + h)(5 - 27h)}{(25 + 9h)^2}, \]

\[ v_\perp^2 = \frac{5(1 + h)}{25 + 9h}, \]

\[ \cos 2\psi = \frac{27\sqrt{-h}(1 + h)}{5 - 27h}, \quad \pi/2 < \psi < \pi, \]

and \( \cos 2\phi = \frac{\lambda \sqrt{-h}}{5}, 0 < \phi < \pi/2 \).

Eigenvalues:

\[ \lambda_{1,2} = \lambda_{3,4} = -\frac{3(5 - 3h)}{(25 + 9h)} \left[ 1 + \frac{20(1 + h)(25 + 9h)}{(5 - 3h)^2} \right] \]

\[ \lambda_{5,6} = \frac{15(1 + h)}{25 + 9h}, \quad \lambda_\ast = \frac{15(1 + h)}{25 + 9h} \left( 5\gamma - 6 \right). \]

This equilibrium point is stable for \( g > 6/5 \).

(4) \( E_3(h) \), \(-1 < h < -1/9 \) and \( 0 < g < 2 \), \( k = -\sqrt{\frac{1}{g}} \):

\[ \Sigma_{12} = \Sigma_{23} = \lambda = 0, \quad \Sigma_\ast = -\frac{(3k^2 + 6k - 1)}{4(3k - 1)}, \quad \Sigma_\ast = -\sqrt{\frac{3}{4}} \left( \frac{1 + 6k + k^2}{1 - 3k} \right), \]

\[ N = \frac{3(1 - k)}{2(1 - 3k)^2}, \quad A = \sqrt{3hN}, \quad \Sigma_{13} = \sqrt{\frac{3(1 - 4k - k^2)(1 + k)^2}{4(1 - 3k)^2}}, \]

\[ \Omega = \frac{3(1 - k^2)(1 + 3k)}{2(1 - 3k)^2}, \quad v_1 = \frac{1 + k}{\sqrt{2(1 - k)}}, \quad v_2 = \frac{1 - 4k - k^2}{2(1 - k)}. \]
This equilibrium point lies in $T_2^-(VI_h)$. Eigenvalues:

$$
\lambda_1 = -\frac{3(1 - 4k - k^2)}{2(1 - 3k)},
$$

$$
\lambda_{2,3} = -\frac{3(1 - k)^2}{4(1 - 3k)} \left[ 1 \pm \sqrt{1 - \frac{32(1 - 4k - k^2)(1 + k)}{(1 - k)^2}} \right],
$$

$$
\lambda_4 = -\frac{3(1 - 4k - k^2)(\gamma - 1)}{(1 - 3k)(2 - \gamma)}, \quad \lambda_{5,6} = \lambda_{2,3}, \quad \lambda_7 = \lambda_1.
$$

This point is stable for $\gamma > 1$.

(5) $\mathcal{R} \mathcal{E}(h), 0 < \gamma < 2, h < 0$:

$$
\Sigma_{12} = \Sigma_{13} = \Sigma_{23} = v_2 = v_3 = 0, \quad \Sigma_- = N = (1 - \ell)\sqrt{-\Sigma_+(1 + \Sigma_+)}.
$$

$$
A = (1 + \Sigma_+), \quad v_1 = 1, \quad -1 < \Sigma_+ < 0, \quad 0 < \ell < 1, \quad |\lambda| < 1.
$$

The group parameter is given by $3h\Sigma_+(1 - \lambda^2)(1 - \ell) = (1 + \Sigma_+)$. These equilibrium points correspond to a non-vacuum plane wave with an extremely tilted fluid. These equilibrium points lie in $T_1(VI_h)$ and are always unstable.

### 3.3. Special equilibrium points for $h = -1/9$

(1) $\mathcal{C} \mathcal{F}$. The Collinson–French (Robinson–Trautmann) solution is given by:

$$
\Sigma_+ = -\frac{4}{3}, \quad \Sigma_- = \frac{1}{3\sqrt{3}}, \quad \Sigma_{13} = \frac{\sqrt{2}}{9}, \quad N = \frac{1}{\sqrt{2}}, \quad A = \frac{1}{\sqrt{2}}, \quad \Sigma_{12} = \Sigma_{23} = \Omega = \lambda = 0.
$$

As for the plane waves the $v_i$-equations decouple and we can again treat these separately. The special case, $h = -1/9$ leads to the exact vanishing of one of the constraint equations, and hence the tilt velocity can only have two independent components (and we set $v_3 = 0$).

There are the following equilibrium points associated with the Collinson–French solution:

(1) $\mathcal{C} \mathcal{F}_0 : v_1 = v_2 = 0, 0 < \gamma < 2$.

(2) $\mathcal{C} \mathcal{F}_{\pm} : v_1 = -\frac{\sqrt{6(3\gamma - 4)}}{2(3 - \gamma)}, v_2 = \pm \frac{\sqrt{6(3\gamma - 4)(3 - 2\gamma)}}{\sqrt{2(3 - \gamma)}}, \quad \frac{4}{3} < \gamma < \frac{3}{2}.$

(3) $\mathcal{C} \mathcal{F}_2 : v_1 = \frac{\sqrt{6(9\gamma - 14)}}{6\gamma - 11}, v_2 = 0, \quad \frac{24 - \sqrt{6}}{15} < \gamma < \frac{24 + \sqrt{6}}{15}.$

(4) $\mathcal{C} \mathcal{F}_{\pm} : v_1 = \pm 1, v_2 = 0, 0 < \gamma < 2$.

These equilibrium points, and their stability, were studied in [1].

(2) $\mathcal{W}$. Wainwright $\gamma = 10/9$ solution

$$
\Sigma_+ = -\frac{4}{3}, \quad \Sigma_- = \frac{1}{3\sqrt{3}}, \quad 0 < \Sigma_{13} < \frac{\sqrt{2}}{9}, \quad N = \frac{1}{6}\sqrt{8 + 54\Sigma_{13}^2},
$$

$$
A = \frac{1}{\sqrt{3}}N, \quad \Omega = \frac{\sqrt{2}}{9} - 3\Sigma_{13}^2, \quad \Sigma_{12} = \Sigma_{23} = \lambda = V = 0.
$$

This line bifurcation was studied in [16] and found to be stable in $T(VI_h)$ for $h = -1/9$. 

3.4. Special equilibrium points for $h = -1$

(1) $\mathcal{P}(III)$. There is a special line bifurcation of ‘tilted’ vacuum solutions for $h = -1, \gamma = 1$:

$$\Sigma_\pm = -\frac{1}{4}, \quad \Sigma_\pm = N = \frac{\sqrt{3}}{4}, \quad A = \frac{3}{4}, \quad \Sigma_{12} = \Sigma_{13} = \Sigma_{23} = \lambda = 0, \quad v_1 = v_2 = 0, \quad 0 < v_3 < 1.$$ 

The extreme limit of this equilibrium point, $\lim_{v_3 \to 1} \mathcal{P}(III) = \tilde{E}^{-p}(h)|_{(h, r) = (-1, 1)}$. We will call $\tilde{E}^{-p}(h)|_{(h, r) = (-1, 1)}$ for simplicity. We will also define $P_0(III) \equiv \lim_{v_3 \to 0} \mathcal{P}(III) = L(h)|_{(h, r) = (-1, 1)}$. These solutions are, in fact, locally rotationally symmetric (LRS).

Regarding the eigenvalues, there are three eigenvalues which are zero and the rest all have a negative real part. In order to resolve the stability properties of these equilibrium points one has to resort to centre manifold theory.

(2) $P_0(III) \equiv L(h)|_{(h, r) = (-1, 1)}$.

(3) $E^{-p}(III) \equiv \tilde{E}^{-p}(h)|_{(h, r) = (-1, 1)}$.

3.5. New self-similar solutions

As we have provided a complete catalogue of equilibrium points for the tilted-type VI$_b$ model, it is of interest to discuss which of these solutions correspond to new solutions. The physically interesting solutions are the intermediately tilted non-vacuum points which correspond to exact vortic self-similar solutions of type VI$_b$. Self-similar solutions of type VI$_b$ were studied by Rosquist and Jantzen [35]; however, only some type VI$_0$ solutions were found explicitly. The solutions $R^{-}(h)$ appear to have been found by Apostolopoulos in [36]. Moreover, the $h = -1/9$ case of $R^{+}(h)$ appears also to be found by Apostolopoulos in [34]. However, the remaining solutions $R^{+}(h)$ for $h \neq -1/9$ seem to be new and have not been given previously in the literature. Furthermore, the exact $\gamma = 6/5$ solutions corresponding to $B(h)$ also appear to be new (although the case $h = 0$ was given in [37, 28]).

Regarding the extremely tilted non-vacuum equilibrium points, $E^{+\pm}(h), E^{-\pm}(h)$ and $E_{2}(h)$, these also correspond to exact solutions. We see these equilibrium points exist for all $\gamma \in (0, 2)$; however for $\gamma \neq 4/3$ the physical interpretation of these is unclear. For $\gamma = 4/3$, we can interpret these solutions as Bianchi type VI$_b$ cosmologies containing null radiation.

The remaining solutions listed are either known or implicitly known [1, 2].

4. Late-time behaviour

Let us discuss the different late-time behaviour.

4.1. The realm of the plane waves

For the type VII$_b$ and the type IV universes, the vacuum plane waves played a vital role in the future evolution [22]. These plane-wave solutions were also shown to possess a wealth of interesting phenomena, like attracting closed orbits and attracting tori. Since the type IV model is the $h \to -\infty$ limit of type VI$_b$ models, we expect to find that the plane wave solutions play an important role for, at least, some of the type VI$_b$ models.

In the Bianchi type VI$_b$ case all of the plane-wave equilibrium points reside in the invariant subspaces $N^{\pm}(VI_b)$. It is illustrative to consider the subspaces $T_{2}^{\pm}(VI_b) \subset N^{\pm}(VI_b)$ (partly because it is easier to interpret, e.g., the figures for $N^{\pm}(VI_b)$ would be three dimensional).
Late-time behaviour of the tilted Bianchi type VI\textsubscript{h} models

Figure 2. The regions of stability of the plane-wave solutions in the invariant subspaces $T^{\pm}_2(\text{VI}_h)$. Here $K^2 = -1/h$ and $K < 0$ corresponds to $T^{-}_2(\text{VI}_h)$ while $K > 0$ corresponds to $T^{+}_2(\text{VI}_h)$. The dashed line corresponds to the lower boundary of the region marked $\tilde{L}_-(h)$. The loophole is shown for $K > 0$ but has been suppressed for $K < 0$.

The equilibrium points in $T^{\pm}_2(\text{VI}_h)$ are those with $r = 1$. In $T^{\pm}_2(\text{VI}_h)$ the regions where the various plane-wave equilibrium points are stable are depicted in figure 2. The dashed line indicates the lower bound of stability for $\tilde{L}_-(h)$. We can see that there are only stable plane waves for $h \leq -1$ in $T^{-}_2(\text{VI}_h)$ and $h \leq -1/9$ in $T^{+}_2(\text{VI}_h)$. For the fully tilted models (i.e., in $T(\text{VI}_h)$), only the plane waves in $T^{-}_2(\text{VI}_h)$ remain stable (i.e., the ones with $-1 \leq K \leq 0$ in figure 2); all plane waves in $T^{+}_2(\text{VI}_h)$ are unstable in $T(\text{VI}_h)$.

4.1.1. Hopf-bifurcation and the loophole. The loophole is defined as the set of plane waves where the variable $\gamma$ satisfies the following: given $K$ and $r = \sqrt{1-\lambda^2}$ where $r(r-\sqrt{r^2+1}) < K < r(r+\sqrt{r^2+1})$, then $\gamma_0 < \gamma < 2(K^2+3r^2)/(K^2+5r^2)$ where $\gamma_0$ is implicitly defined by $F(K, r, \gamma_0) = 0$, where $F$ is defined in section 3.2.4, item (4). In the loophole, there are no stable equilibrium points, so we need to look for other potential candidates for late-time attractors.

In [1, 22], we noted that the corresponding loopholes in type IV and type VII\textsubscript{h} models had closed curves and tori as attractors; hence, we need to look for closed curves in the type VI\textsubscript{h} loophole as well. The important observation regarding the nature of the attractor can be seen from the eigenvalues $\lambda_6$ and $\lambda_7$ for the equilibrium point $\tilde{F}^\pm(h)$. As we vary $\gamma$, we note
Figure 3. Magnified region of figure 2 showing the loophole in $T^-$ (VIh). The curve marked $F = 0$ is defined by $F(K, r, \gamma) = 0$, where the function $F$ is defined in section 3.2.4, item (3.2.4). Part of this curve marks the threshold value of stability for the equilibrium point $\tilde{F}^-(h)$.

the following (sufficiently close to $\gamma_0$):

- $\gamma < \gamma_0 : \lambda_6 + \lambda_7 < 0, \lambda_6 \lambda_7 > 0$.
- $\gamma = \gamma_0 : \lambda_6 + \lambda_7 = 0, \lambda_6 \lambda_7 > 0$.
- $\gamma > \gamma_0 : \lambda_6 + \lambda_7 > 0, \lambda_6 \lambda_7 > 0$.

This implies that the real values of $\lambda_{6,7}$ change sign while the imaginary values remain non-zero; this is an indication of a possible Hopf-bifurcation.

Consider a two-dimensional dynamical system given by the complex variable $Z$. The normal form of a Hopf-bifurcation can be written as

$$Z' = (\lambda + b |Z|^2)Z,$$

(4.1)

where $b$ is some complex number and $\lambda$ is a parameter. If $\text{Re}(b)$ is negative then there are stable closed orbits for $\lambda > 0$. In order to determine whether our system experiences a Hopf-bifurcation as we vary $K, r$ and $\gamma$ we thus need to expand to third order in the variables. This has proven to be difficult in practice due to the complicated dependence on the parameters $K, r$ and $\gamma$; however, there is analytic as well as numerical evidence that the fixed points $\tilde{F}^\pm (h)$ do indeed experience a Hopf-bifurcation and produce a stable closed orbit as $\gamma$ passes through $\gamma_0$ for the following ranges:

$\tilde{F}^+(h) : r^2 < K < r(r + \sqrt{r^2 + 1}), \quad \tilde{F}^-(h) : r(r - \sqrt{r^2 + 1}) < K < 0$.

This does indicate that there are attracting closed curves even outside the loophole; however, outside the loophole these attracting curves will co-exist with attracting equilibrium points. Inside the loophole, on the other hand, only the closed curves can be attractors as all the equilibrium points are unstable. The family of such attracting closed orbits, regardless whether they are outside or inside the loophole, will be referred to as the Mussel attractor. For numerical plots of the Mussel attractor outside the loophole, see figures 8 and 14.
Let us study these closed curves in more detail. As in [22], we consider the tilt-equations in a plane-wave background. We utilize the identity

\[(v_2^2 + v_3^2)^2 = (2v_2v_3)^2 + (v_3^2 - v_2^2)^2,\]

and define \((x, \rho, \theta)\) by

\[x = v_1, \quad \rho = v_2^2 + v_3^2, \quad 2v_2v_3 = \rho \sin \theta, \quad (v_3^2 - v_2^2) = \rho \cos \theta.\]  \(4.2\)

Then we have for the reduced system

\[
\begin{align*}
    x' &= (T + 2\Sigma^*) x - (A^* + \sqrt{3} N^* \cos \theta) \rho, \\
    \rho' &= 2(T - \Sigma^* + A^* x - \alpha \cos \theta) \rho, \\
    \theta' &= 2\alpha(\lambda^* + \sin \theta),
\end{align*}
\]

where \(\alpha = \sqrt{3}(1 - x)N^*\) and, by use of the discrete symmetry \(\phi_4\), we can assume that \(0 \leq \theta < 2\pi\). Furthermore, these variables are bounded by

\[0 \leq \rho, \quad V^2 = x^2 + \rho \leq 1, \quad |\lambda^*| < 1.\]  \(4.4\)

An asterisk has been added to the variables to emphasize that these should be thought of as the limit values for the full system.

For a periodic orbit, \(c(\tau)\), with period \(T_n\), we introduce the average of a variable \(B\):

\[
\langle B \rangle \equiv \frac{1}{T_n} \int_c B \, d\tau.
\]

We can also say something about the stability of a closed periodic orbit. For example, consider the evolution equation for \(\Omega\), which we write as \(\mathcal{Q}' = \lambda_{\Omega} \mathcal{Q}\). Assume that \(c(\tau)\) is a closed periodic orbit with period \(T_n\). Then \(\langle \lambda_{\Omega} \rangle\) indicates the stability of the closed curve with respect to the variable \(\Omega\).

We note that \(N^\pm(VI_h)\) intersect at \(\sin \theta = -\lambda^*\), where

- \(N^+(VI_h)\) : \(\cos \theta = +\sqrt{1 - (\lambda^*)^2} = +r\),
- \(N^-(VI_h)\) : \(\cos \theta = -\sqrt{1 - (\lambda^*)^2} = -r\).

It is in these subspaces that the closed curves must exist. We also note that the variable \(\theta\) induces transitions \(N^+(VI_h) \rightarrow N^-(VI_h)\) which means that in \(T(VI_h)\), \(N^+(VI_h)\) is unstable.

**Theorem 4.1.** Assume that there is a closed properly periodic orbit, \(C_M\) parametrized by \(c(\tau)\), for the dynamical system \(4.3\). Then

\[
\begin{align*}
    \langle x \rangle &= -\frac{\gamma(K^2 + 3r^2) - (K^2 + Kr^2 + 4r^2)}{r^2(3 - 2\gamma + K)}, \\
    \langle \lambda_{\Omega} \rangle &= -\frac{3(K^2 + r^2)(5 + K)\gamma - 2(3 + K)}{(K^2 + 3r^2)(3 - 2\gamma + K)}.
\end{align*}
\]

**Proof.** The proof is analogous to that in the type IV case; see [22].

Inside the loophole existence can also be proven.

**Theorem 4.2** (Mussel attractor). For \(\lambda^* < 1\) and every \(K\) and \(\gamma\) taking values in the type VI\(_h\) loophole there exists a closed periodic orbit, \(C_M\), for the dynamical system \(4.3\).

**Proof.** The proof is analogous to that in the type IV case [22] and goes as follows. Inside the loophole there are no attracting equilibrium points. By restricting to the two-dimensional set \(\cos \theta = \pm r\), we get a picture similar to figure 4. The equilibrium points (labelled \(A\), \(B\), \(C\) and \(F\)) are all hyperbolic and are sources/saddles as indicated. We note that the boundary consists
of heteroclinic orbits (also drawn). We now see that there is an orbit from $B$ which cannot end at an equilibrium point and consequently must approach a closed curve. More explicitly, a future trapping region can be constructed as follows. We can use the shadowing theorem (see proposition 4.2 in [2]) and the fact that the equilibrium points are all hyperbolic to show that there is an orbit, $c_1$, originating from $A$ which can be chosen to come arbitrary close to $C$ and $B$ (also shown in figure 4). Similarly, there is an orbit, $c_2$, originating from $A$ and coming arbitrary close to $B$. We can then cut out neighbourhoods of the points $A$ and $B$ using the dotted curves, $d_A, d_B$, so that $c_1, c_2, d_A, d_B$ constitute the boundary of a future trapping region. Since the only equilibrium point inside this trapping region is the source $F$, the Poincaré–Bendixson theorem implies the existence of a closed periodic orbit (in particular, there must be an orbit originating from $x = \rho = 0$ that approaches a closed orbit).

There is an important corollary that follows from this.

**Corollary 4.3.** For $h < -(3 - 2\sqrt{2})$, there exist closed periodic orbits in $T(VI_h)$.

The ramifications of this result are that considering the equilibrium points only is not sufficient to determine the asymptotic behaviour for these models. However, apart from the closed periodic orbits described above (the Mussel attractor), we have not found evidence for any other closed period orbits (for $h \neq -1/9$) important for the late-time behaviour.
Late-time behaviour of the tilted Bianchi type VI\(_h\) models

4.2. The realm of non-vacuum vortic universes

We note that all equilibrium points with \(\Omega \neq 0\) in \(N^\pm(VI_h)\) are, in fact, in \(T^\pm_2(VI_h)\). The regions of the stability of the equilibrium points in \(T^+_2(VI_h)\) are depicted in figure 5. For \(N^\pm(VI_h)\), the picture is identical.

In the fully tilted space \(T(VI_h)\), we note that from the monotonic function \(Z_2\), if \(\Omega\) approaches a non-zero value at late times, then \(D \to 0\) and \(V \to 1\) for \(\gamma < 6/5\) and \(\gamma > 6/5\), respectively. Our analysis indicates that the future asymptote is non-vacuum for \(-1 < h < -1/9\) and \(-1/9 < h \leq 0\), for which we have the following behaviour (see figure 6):

1. \(-1 < h < -1/9:\)
   (a) \(2/3 < \gamma \leq 1\): \(D \to 0\), and \(V \to 0\). Attractor \(C(h)\).
   (b) \(1 < \gamma < \frac{2(3+\sqrt{-h})}{5+3\sqrt{-h}}\): \(D \to 0\), and \(V \to 0\) or \(V \to 1\). Attractors \(C(h)\) and \(E_3(h)\).
   (c) \(\frac{2(3+\sqrt{-h})}{5+3\sqrt{-h}} \leq \gamma < 2\): \(D \to 0\), and \(V \to 1\). Attractor \(E_1(h)\).

2. \(-1/9 < h \leq 0:\)
   (a) \(2/3 < \gamma \leq \frac{2(3+\sqrt{-h})}{5+3\sqrt{-h}}\): \(D \to 0\), and \(V \to 0\). Attractor \(C(h)\).
   (b) \(\frac{2(3+\sqrt{-h})}{5+3\sqrt{-h}} < \gamma < \frac{6}{5}\): \(D \to 0\), and \(V \to\) constant. Attractor \(R^-(h)\).
   (c) \(\gamma = \frac{6}{5}\): \(D \to\) constant, and \(V \to\) constant. Attractor \(B(h)\).
   (d) \(\frac{6}{5} < \gamma < 2\): \(D \to\) constant, and \(V \to 1\). Attractor \(E_2(h)\).
Figure 6. The asymptotic behaviour of tilted-type VI$_h$ universes. For $h < -1$ we have used the solutions in $T_2^{-}(VI_{h})$ for illustrative purposes only (the figure should be three dimensional). Again the loophole has been suppressed.

4.3. The case $h = -1$: Bianchi type III

The case $h = -1$ is a special case which has to be treated separately. For $2/3 < \gamma < 1$ the Collins solution, $C(h)$ is the only attractor. All eigenvalues have negative real parts and consequently the stability can be deduced from the linearized analysis. However, for $\gamma = 1$ and $\gamma > 1$, the equilibrium points $P_{III}$ (including the non-tilted and extreme limits) and $E_{p}^{-}(III)$ have three and two zero-eigenvalues, respectively. In order to determine the stability for these solutions one must therefore go to higher order.

Consider first $\gamma = 1$. Two of the zero-eigenvalues for $P(III)$, $0 < v_3 < 1$ correspond to a non-trivial Jordan block

$$ J_1 = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}. $$

This means that the generic solution drifts along the line of equilibria. The solution drifts towards the $v_3 = 0$ solution, $P_0(III)$. It is therefore of interest to study the centre manifold for $P_0(III)$.

4.3.1. $T_2^{-}(VI_{-1})$: the centre manifold. In our analysis of the centre manifold we restrict ourselves to the invariant subspace $T_2^{-}(VI_{-1})$. This subspace has only a two-dimensional centre manifold which makes the analysis more tractable and easier for illustrative purposes.
It is useful to define the new variables

\[ \hat{\Sigma}_+ = \frac{1}{2}(-\Sigma_+ + \sqrt{3}\Sigma_-), \quad \hat{\Sigma}_- = \frac{1}{2}(\sqrt{3}\Sigma_+ + \Sigma_-). \]  

(4.7)

The centre manifold can be found as follows. Define \((x, y, z, w)\) by

\[ (\hat{\Sigma}_+, N, v_1, v_3) = \left( \frac{1}{2} + x, \sqrt{3}y(1 + y), z, w \right). \]

The variables \(\hat{\Sigma}_-\), \(\Omega\) and \(\Sigma_{13}\) can be determined from the constraints.

By introducing the variables \((X, Y, Z, W)\) as follows:

\[ (X, Y, Z, W) = (x + \frac{1}{2}y, x - \frac{1}{2}y, -x - \frac{1}{2}y + w, -x + \frac{1}{2}y + z), \]

we can expand the differential equations for \((X, Y, Z, W)\) to second order. The centre manifold can then be seen to be parametrized by \((X, Z)\). Moreover, on the centre manifold \((Y, W) = O(3), \) where \(O(3)\) means cubic in \(X\) and \(Z.\) The equations for \((X, Z)\) to lowest order are then

\[ X' = X^2 + O(3), \quad Z' = XZ + O(3). \]  

(4.8)

Requiring \(\Omega \geq 0\), gives the approximate solutions at late times:

\[ X = -\frac{1}{r}, \quad Z = \frac{C}{r}, \]

where \(C\) is a constant. Substituting these back into the original variables, the decay-rates are found to be

\[ \hat{\Sigma}_+ = \frac{1}{2} \left(1 - \frac{1}{r}\right), \quad \hat{\Sigma}_- = O\left(\frac{1}{r^3}\right), \quad \Sigma_{13} = \frac{2v_{3,0}}{\sqrt{3}r^2}, \quad N = \frac{\sqrt{3}}{4} \left(1 - \frac{1}{3r}\right), \quad \Omega = \frac{1}{r}, \quad v_1 = O\left(\frac{1}{r^3}\right), \quad v_3 = \frac{v_{3,0}}{r}. \]  

(4.9)

Here, the constant \(v_{3,0}\) is related to \(C\) by \(C = 1 + v_{3,0}.\) These decay rates have also been confirmed numerically. We have also simulated the system in the fully tilted space \(T(VI_{h})\) which does, indeed, confirm that the decay rates have the functional dependence as given above. The numerics also suggest that

\[ \lambda = O\left(\frac{1}{r^2}\right), \quad \Sigma_{23} = O\left(\frac{1}{r^3}\right), \quad v_2 = O\left(\frac{1}{r^3}\right), \quad \Sigma_{12} = O\left(\frac{1}{r^4}\right). \]  

(4.10)

Hence, it is plausible that \(\mathcal{P}_0(III)\) is the attractor for the fully tilted dust \((\gamma = 1)\) type III model.

For \(1 < \gamma < 2\) the situation is easier. Again the most promising candidate possesses zero eigenvalues; however, we note that

\[ \mathcal{E}_p(III) \equiv \lim_{h \rightarrow -1} \mathcal{E}_p(h) = \lim_{h \rightarrow -1} \mathcal{E}_3(h). \]

Also, for \(1 < \gamma < 2, \mathcal{E}_p(h), \mathcal{E}_3(h)\) are the attractors for \(h < -1\) and \(h > -1\) (sufficiently close to \(-1\)), respectively; hence, we would anticipate that \(\mathcal{E}_p(III)\) is the attractor for \(h = -1\) and \(1 < \gamma < 2\). Indeed, doing a centre manifold analysis for the subspace \(T_{-1}^{-}(VI_{-1})\) we get

\[ \hat{\Sigma}_+ = \frac{1}{2} + O\left(\frac{1}{r}\right), \quad N = \frac{\sqrt{3}}{4} + O\left(\frac{1}{r^2}\right), \quad v_1 = O\left(\frac{1}{r}\right), \quad v_3 = 1 + O\left(\frac{1}{r^2}\right), \quad \Omega = O\left(\frac{1}{r}\right). \]  

(4.11)

This confirms that the type III models with \(1 < \gamma < 2\) at late times approach the extremely tilted vacuum solution \(\mathcal{E}_p(III).\)
Note that we have only presented here a centre manifold analysis for the invariant subspace \( T^{-}(VI_{-1}) \). A full analysis of these centre manifolds has been performed showing that these equilibrium points are indeed the late-time attractors; however, due to the lengthy and complicated nature of the centre manifold analysis, this analysis will be presented elsewhere.

There is an interesting connection with the type VIII models [32] worth pointing out. We note that the type III solutions approach an LRS universe at late times. In fact, type III LRS solutions also admit a type VIII action. Comparing the attractors for type III and type VIII we note that there is a striking similarity. In terms of the metric and the matter (in a \( C^0 \) sense), the type III and type VIII attractors are the same. Explicitly, the curvature \( A^2 + N^2 \) in the type III model takes the role of \( -\frac{N}{\bar{N}} \) in the type VIII model. In fact, by comparing the decay rates we even see that some of the decay rates are identical to lowest order. On the other hand, the two models do approach this attractor differently since the Weyl parameter diverges for type VIII while it is always bounded for type III.

4.4. The case \( h = -1/9 \)

Based on the eigenvalues of the equilibrium points, the equilibrium points are future attractors in the range specified [1]:

1. \( \mathcal{CF}_0 : 10/9 < \gamma \leq 4/3 \).
2. \( \mathcal{CF}_{1\pm} : \frac{4}{3} < \gamma < \frac{5}{6} + \frac{\sqrt{721}}{42} \).
3. \( \mathcal{CF}_2 : \) never an attractor.
4. \( \mathcal{ECF}_- : \frac{24 - \sqrt{6}}{15} < \gamma < 2 \).

Including the analysis of the non-tilted equilibrium points we can thus conclude

- \( 2/3 < \gamma < 10/9 \): Collins type VI\( -1/9 \) perfect fluid solution is stable.
- \( \gamma = 10/9 \): Wainwright’s type VI\( ^*_{-1/9} \), \( \gamma = 10/9 \), solution is stable.
- \( 10/9 < \gamma < 2 \): The Collinson–French vacuum is stable. Moreover, for \( 4/3 < \gamma \) the asymptotic tilt velocity is non-zero.

It should be emphasized that the analysis of this model is not quite complete. Due to the exact vanishing of one of the constraint equations a different approach has to be taken regarding the numerical analysis. Furthermore, the question of whether there are closed periodic orbits acting as attractors has not been addressed in this paper. Preliminary analysis indicates that this model also possesses closed periodic orbits [38].

5. Numerical analysis

5.1. Additional numerical support

In the qualitative analysis of the system of equations governing the evolution of the tilted Bianchi type VI\( h \) models, it was found that there were numerous possible future asymptotic states. In addition, it was also found that in the invariant set \( T_h^{+} (VI_h) \) there is a portion of the parameter space, the loophole, in which there is no equilibrium point acting as a future asymptotic attractor. An extensive numerical analysis has been completed that further supports the qualitative analysis presented in the paper. In addition to obtaining numerical evidence for all behaviour for the general-type VI\( h \), and in the special case of the invariant set \( T_h^{+} (VI_h) \), some very special and even somewhat surprising results have been found. Below we include a select group of numerical plots that illustrate some of the rich behaviour found in the type VI\( h \) models. More details and numerical plots can be found in the companion article [39].
5.2. The invariant set $T_2^+ (VI_h)$.

Here, we are looking at the dynamics in the four-dimensional invariant set $T_2^+ (VI_h)$. (Recall that $\Sigma_{13} = \Sigma_{23} = \lambda = v_3 = 0$, and $A = \sqrt{-3hN}$ in the $T_2^+ (VI_h)$ invariant set.) A six-dimensional set of differential equations for the variables $\{\Sigma_+, \Sigma_-, \Sigma_{12}, N, v_1, v_2\}$ was integrated using typical values for the parameters $h$ and $\gamma$ that illustrate some different asymptotic behaviour. The constraint equations were used to check the accuracy of the numerical integrations. The built-in differential equations solver ode45 in Matlab R2006a has been used to numerically solve all cases. The relative tolerance was set to $10^{-12}$ and the absolute tolerance was set to $10^{-20}$ or smaller. The constraint equations were used to determine the initial values of the tilt velocities $v_1, v_2$. Two numerical plots, figures 7 and 8, are included here that show some of the more surprising (albeit not totally unexpected) behaviour in the invariant set $T_2^+ (VI_h)$. Note the figures included here do not show typical behaviour for the entire range of parameter space for $T_2^+ (VI_h)$, but only illustrate what is typical for small neighbourhoods around the selected parameter values. Indeed other behaviours are possible; there are additional situations when the future attractor is not unique, although no others show evidence of closed orbits. For additional illustrations see the companion article [39].

In figure 7, we observe four periods of the variable $V^2$ and the corresponding Mussel attractor in the accompanying $v_1$–$v_2$ phase portrait. The existence of this closed orbit was predicted, since the lack of a stable equilibrium point inside the loophole and the previous analysis of the Bianchi type VIIh and IV suggested that it must be true for at least some class of the type VIh models. However, what was not predicted before the numerical analysis was completed was the existence of a closed orbit for parameter values outside the loophole.

Figure 7. The invariant set $T_2^+ (VI_h) : h = -\frac{1}{5}, \gamma = 1.59$. Attractor is the Mussel attractor. Initial conditions were chosen to be $\Sigma_+ = 3/10 - i/10, \Sigma_- = -0.3 + i/10, \Sigma_{12} = 4/10, N = i/20$, where $i$ ranges from 1 to 4.
Figure 8 shows that it is indeed possible to have a Mussel attractor for parameter values outside the loophole. In addition, in this situation it can be seen that there are two attractors, the Mussel attractor which shows a periodic nature in the variable $V^2$ and the equilibrium point $\tilde{L}^-(h)$, which is extremely tilted.

5.3. Fully tilted Bianchi VI$^h$ space

Typical values of the parameters $h$ and $\gamma$ are chosen to illustrate some of the interesting future asymptotic behaviour found in the fully tilted Bianchi VI$^h$ models, see figures 9–14. For the interested reader, additional figures can be found in the companion article [39]. In each numerical run we choose essentially the same set of initial conditions unless otherwise indicated. Given initial values for $\{\Sigma_+, \Sigma_-, \Sigma_{12}, \Sigma_{13}, \Sigma_{23}, N, \lambda\}$, initial values for $A, v_1, v_2, v_3$ were determined by solving the constraint equations. For all cases except $h = -5/9$, the built-in differential equations solver ode45 in Matlab R2006a was used to numerically solve all cases. The relative tolerance was set to $10^{-12}$ and the absolute tolerance was set to $10^{-20}$. The full eleven-dimensional set of differential equations was integrated while the constraint equations were graphed (not included here) and used to determine when and if the numerical analysis breaks down. In the case $h = -5/9$, due to instabilities of the constraint surfaces, an alternative approach had to be taken. The built-in differential equations solver ode15s in Matlab R2006a was used to numerically solve this case. Instead of integrating the eleven-dimensional set of differential equations for the quantities $\{\Sigma_+, \Sigma_-, \Sigma_{12}, \Sigma_{13}, \Sigma_{23}, N, \lambda, A, v_1, v_2, v_3\}$, a seven-dimensional set of differential equations for $\{\Sigma_+ , \Sigma_- , \Sigma_{12} , \Sigma_{13} , \Sigma_{23} , N , \lambda\}$ and a set of algebraic constraints for $A, v_1, v_2, v_3$.
were integrated. Again the constraint equations were also graphed (not included here) and used to determine when and if the numerical analysis broke down. The relative tolerance was set to $10^{-12}$ and the absolute tolerance was set to $10^{-15}$. In each phase portrait stars indicate the future attractor.

Figure 9 shows a partial picture of the non-isolated nature of the stable attractor $B(h)$. In the $\{v_1 \sqrt{v_1^2 + v_2^2}\}$ phase portrait, the lower bound (as seen in the phase portrait) of this non-isolated attractor is the equilibrium point $R^-(h)$ (which is stable if the value of $\gamma$ is a little less than the critical value of $6/5$) while the upper bound (not seen in the phase portrait) of this non-isolated attractor is the equilibrium point $E^2(h)$ (which is stable if the value of $\gamma$ is larger than the critical value of $6/5$). Figure 10 gives an illustration of a situation in which there are two stable equilibrium points in the fully tilted Bianchi $VI_h$ models. Figure 11 shows the strongly attracting nature of the heteroclinic orbit between $C(h)$ and $E_1(h)$. Figure 12 not only shows the strongly attracting nature of the heteroclinic orbit between $C(h)$ and $E_3(h)$, but also the non-isolated nature of the equilibrium point $F^-(h)$. We also note how the variables $\{\Omega, N, \Sigma^2, \lambda\}$ obtain their equilibrium values much much faster than the tilt velocities. This behaviour is akin to the freezing in behaviour observed in the types $VII_h$ and $IV$ models [1, 22]. Again we observe this same freezing in behaviour and the non-isolated nature of the equilibrium point $E_1^-(h)$ in figure 13. Figure 14 illustrates something that was not predicted in the previous qualitative analysis, that is, the existence of two stable attractors, a stable equilibrium point $L^-(h)$ and a stable closed orbit. The parameter values $h = -9, \gamma = 1.241$ used in figure 14 would be considered outside the three-dimensional analogue of the loophole.
Figure 10. Fully tilted Bianchi VI$^h$: $h = -5/9, \gamma = 1.035$. Attractors are $C(h)$ and $E_3(h)$. The initial conditions are chosen to be $\Sigma_{1i} = 0, \Sigma_{-i} = -0.3 + \frac{i}{6}, \Sigma_{12} = 0.4, \Sigma_{13} = 0.2, \Sigma_{23} = 0.2, N = \frac{1}{6}, \lambda = 0.6 - \frac{i}{4}$ with $i$ ranging from 1 to 6. Note the slow transition which is due to a relatively small eigenvalue $\lambda \sim 0.02$ of the unstable equilibrium point $R^-(h)$.

6. Discussion

In this paper, we have used dynamical systems methods and detailed numerical experimentation to investigate the future asymptotic properties of SH Bianchi type VI$^h$ cosmological models. We have determined all of the equilibrium points of the type VI$^h$ state space. These equilibrium points correspond to exact self-similar solutions of the Einstein equations (some of which are new exact solutions) and play an important role in describing the general evolution of the system. The stability of all of these equilibrium points is also investigated. In particular, we have determined all possible late-time behaviour for Bianchi type VI$^h$ models. All of the possible future asymptotic behaviour for all Bianchi models (except Bianchi type IX models, which can recollapse) are now known and summarized in table 4; this table is now complete. We note that the Bianchi type VI$^h$ case is of special interest in that it is very complicated and contains many subcases, and many of the different future asymptotic behaviour found in previous work occur in these particular models.

In particular, it was found that the vacuum plane-wave solutions play an important role in the future evolution of type VI$^h$ models (as was the case in the type VII$^h$ and the type IV universes [22]). All of the plane-wave equilibrium points are found to occur in the invariant subspaces $N^\pm(VI_h)$. The regions where the various plane-wave equilibrium points were stable are depicted in figure 2; we recall that for the fully tilted models only the plane waves in $T_{ij}^+ (VI_h)$ are stable.

A loophole exists in which there are no stable equilibrium points, and hence it is necessary to seek other candidates for late-time attractors. It was noted that closed curves and tori
Late-time behaviour of the tilted Bianchi type VI\(_h\) models

act as attractors in the corresponding loopholes in type IV and type VII\(_h\) models [1, 22]. Hence, we looked for closed curves in the type VII\(_h\) loophole. Calculations and numerical experimentation were found to provide plausible evidence that the system experiences a Hopf-bifurcation resulting in a stable closed orbit as \(\gamma\) takes values in a range of parameter values (that includes values not only within the loophole, but also values just outside the loophole). This shows that there are attracting closed curves even outside the loophole; however, outside
Figure 11. Fully tilted Bianchi VI, $h = -5/9, \gamma = 1.10$. Attractor is $\tilde{t}(h)$. The initial conditions are chosen to be $\Sigma_+ = 0.3 - \frac{i}{10}, \Sigma_- = -0.3 + \frac{i}{10}, \Sigma_{12} = 0.4, \Sigma_{13} = 0.2, \Sigma_{23} = 0.2, N = \frac{i}{10}, \lambda = 0.6 - \frac{i}{5}$ with $i$ ranging from 1 to 5.

Figure 12. Fully tilted Bianchi VI, $h = -4, \gamma = 1.17$. Attractor is $\tilde{t}(h)$. The initial conditions are chosen to be $\Sigma_+ = 0.3 - \frac{i}{10}, \Sigma_- = -0.3 + \frac{i}{10}, \Sigma_{12} = 0.4, \Sigma_{13} = 0.2, \Sigma_{23} = 0.2, N = \frac{i}{10}, \lambda = 0.6 - \frac{i}{4}$ with $i$ ranging from 1 to 4.
Late-time behaviour of the tilted Bianchi type VI$_h$ models

Figure 13. Fully tilted Bianchi VI$_h$: $h = -4, \gamma = 1.2$. Attractor is $\tilde{E}^{-}_p(h)$. The initial conditions are chosen to be \( \Sigma_+ = 0.3 - \frac{1}{10}, \Sigma_- = -0.3 + \frac{1}{10}, \Sigma_{12} = 0.4, \Sigma_{13} = 0.2, \Sigma_{23} = 0.2, N = \frac{1}{10}, \lambda = 0.6 - \frac{i}{5} \) with $i$ ranging from 1 to 5.

Figure 14. Fully tilted Bianchi VI$_h$: $h = -9, \gamma = 1.241$. Attractor is $\tilde{L}^{-}_p(h)$ and a closed orbit. The initial conditions are chosen to be $\Sigma_+ = 0.3 - \frac{1}{10}, \Sigma_- = -0.3 + \frac{1}{10}, \Sigma_{12} = 0.4, \Sigma_{13} = 0.2, \Sigma_{23} = 0.2, N = \frac{1}{10}, \lambda = 0.6 - \frac{i}{5} \) with $i$ ranging from 1 to 5.
the loophole these attracting curves will co-exist with attracting equilibrium points and there are consequently a number of possible late-time behaviours. Inside the loophole, however, only the closed curves can be attractors since all of the equilibrium points in the loophole are unstable. The family of attracting closed orbits (both outside and inside the loophole) is referred to as the Mussel attractor.

In more detail, we analytically proved that in the type VI$\beta$ loophole there exists a closed periodic orbit (the Mussel attractor), $\mathcal{C}_M(h)$, for the dynamical system. In addition, we provided convincing numerical evidence that closed orbits exist outside the loophole (see figures 7 and 8). Clearly, an analysis of the equilibrium points alone is not sufficient for determining the future asymptotic behaviour in the Bianchi type VI$\beta$ models. However, we should also note that apart from the Mussel attractor we have found no evidence for any other closed orbits important for the late-time behaviour for $h \neq -1/9$.

The Bianchi type III case (i.e., $h = -1$) is a special case which necessitates a separate treatment. For $2/3 < \gamma < 1$ the Collins solution is the only attractor. However, for $\gamma \geqslant 1$, the corresponding equilibrium points have multiple zero-eigenvalues, and a centre manifold analysis is required. We found that, in the invariant subspace $T_{-}^*(VI_{\beta})$ for $1 < \gamma < 2$, the type III models approach the extremely tilted vacuum solution $\tilde{\mathcal{E}}_{-}^*(III)$ at late times. In addition, based upon a detailed centre manifold analysis in the invariant subspace $T_{-}^*(VI_{\beta})$ and numerical simulations in the fully tilted space $T(VI_{\beta})$, we concluded that it is plausible that $\mathcal{P}_0(III)$ is the attractor for the fully tilted dust ($\gamma = 1$) type III model$^7$.

As noted above, comprehensive numerical experiments were carried out to complement and confirm the analytical results. All of the numerics, which serve as confirmation of all of our analytical results, are summarized in a companion article [39]. In the present paper, we have included several figures (from [39]) that provide typical results (confirming the analytical results) and some specific figures that contain interesting phenomena.

Appendix. Nasty expressions

A.1. Expressions determining $V$, $\phi$ and $\lambda$ for $B(h)$

The following expressions are produced using Maple.

$$V^2 = 2N^2(-1728 - 724275N^6r^6k^4 + 178848N^4k^4r^4 - 11664k^4r^4N^2 - 900N^6r^8k^2$$
$$+ 1350N^8r^{10}k^4 + 26244N^6k^4r^8 + 32940k^4r^8N^6 - 39690k^6r^{10}N^8$$
$$+ 13122k^{10}N^{10} - 625N^6k^4r^2N^2 - 31104k^2r^2N^2 + 150N^4r^6$$
$$+ 80000N^6 + 368550N^8k^4r^2 - 525600k^2r^4N^6 - 170640N^4k^2r^2 - 25000k^6r^8N^8$$
$$+ 414720N^6k^4r^4 + 72075N^6k^2r^6 - 77031N^4k^6r^6 - 100800N^4$$
$$+ 2592k^2r^2 + 864r^2 - 90000N^6r^2 - 126846N^8k^4r^{10} - 8730N^4k^2r^6$$

$^7$ We should also point out that the analysis of the special Bianchi type VI$\_1$, h$^9$ case is not complete either. Due to the exact vanishing of one of the constraint equations a different approach has to be taken regarding the numerical analysis. Furthermore, the question of whether there are closed periodic orbits acting as attractors in this case has not been addressed in this paper; however, a preliminary analysis indicates that such attracting closed curves do indeed exist [38].
Late-time behaviour of the tilted Bianchi type VI$_{a}$ models

\[ + 320 400 k^6 N^8 - 27 054 N^4 k^2 r^4 + 1458 N^4 k_6 r^6 - 1728 N^2 r^4 k^2 
- 259 200 k^4 r^4 N^8 + 80 000 k^2 r^2 N^8 + 358 800 k^2 r^2 N^6 + 270 000 k^2 r^4 N^4 
- 28 800 N^2 r^2 - 13 200 N^4 r^4 + 20 000 N^6 r^4 + 99 600 N^8 r^4 + 1250 N^8 r^8 k^2 
+ 56 862 N^8 k^8 r^8 + 115 668 N^6 k^6 r^8 - 236 520 N^8 k^6 r^6 - 80 550 k^2 r^8 N^8 + 720 N^2 r^4 k^4 
/ \left[ (9k^2 N^2 - 3 + 5N^2) (5103 N^6 k^6 r^6 - 50 625 N^8 k^4 + 40 500 N^6 k^4 r^4 
+ 10 692 N^4 k^4 r^4 - 2475 N^6 k^2 r^6 - 66 600 k^2 r^4 N^4 + 37 800 k^2 r^4 N^4 
+ 50 400 k^2 r^2 N^6 - 32 400 N^4 k^2 r^2 + 1296k^2 r^2 N^2 + 125 N^6 r^6 + 500 N^6 r^4 
- 300 N^4 r^4 - 12 000 N^6 r^2 + 13 200 N^4 r^2 - 3600 r^2 N^2 + 32 000 N^6 - 52 800 N^4 
+ 28 800 N^2 - 5184) \right] \]

(\text{A.1})

\[ \cos(2\phi) = 3(13 851 N^6 k^6 r^6 - 144 585 N^6 k^6 r^6 k^4 - 10 575 N^6 k^4 r^6 + 125 N^6 r^6
