Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Review article

The development of Coronavirus 3C-Like protease (3CL\textsuperscript{PRO}) inhibitors from 2010 to 2020

Proteolytic targeting chimaera (PROTAC)

A B S T R A C T

This review fully describes the coronavirus 3CL\textsuperscript{PRO} peptidomimetic inhibitors and nonpeptidic small molecule inhibitors developed from 2010 to 2020. Specifically, the structural characteristics, binding modes and SARs of these 3CL\textsuperscript{PRO} inhibitors are expounded in detail by division into two categories: peptidomimetic inhibitors mainly utilize electrophilic warhead groups to covalently bind the 3CL\textsuperscript{PRO} Cys145 residue and thereby achieve irreversible inhibition effects, whereas nonpeptidic small molecule inhibitors mainly interact with residues in the S1\textsuperscript{C}, S1, S2 and S4 pockets via hydrogen bonds, hydrophobic bonds and van der Waals forces. Based on the emerging PROTAC technology and the existing 3CL\textsuperscript{PRO} inhibitors, 3CL\textsuperscript{PRO} PROTAC degraders are hypothesised to be next-generation anti-coronavirus drugs.

1. Introduction

1.1. COVID-19 pandemic

Coronavirus disease 2019 (COVID-19) is a highly infectious disease caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), a virus that is closely related to the SARS virus [1]. On May 15, 2020, the COVID-19 pandemic had spread to 210 countries, and more than 4.5 million people had been diagnosed with the infection worldwide [2,3]. SARS-CoV-2 primarily spreads by small droplets expelled by infected individuals when they breathe or cough [4,5]. The infected individuals may either be asymptomatic or develop common COVID-19 symptoms, including fever, cough, fatigue, shortness of breath, and loss of smell [6], and severe cases can progress to complications, including pneumonia, acute respiratory distress syndrome, multi-organ failure, and death [7]. The fatality rate is estimated to be between 3% and 6%. There is no vaccine or specific antiviral treatment for COVID-19, and the available treatments involve symptom management, supportive care, and experimental alternative medicines.

1.2. Coronavirus and SARS-CoV-2

Coronaviruses are species of viruses belonging to the subfamily Orthocoronavirinae in the family Coronaviridae of the order Nidovirales. Coronavirus is a forward single-stranded RNA [8,9], which is endowed with the largest viral genomes (27–32 kb) among the RNA viruses identified to date [10]. Genomic RNA complexes with the basic nucleocapsid protein (N) to form a helical capsid within the membrane. The membrane of all coronaviruses is composed of a minimum of three viral proteins: (a) a spike protein (S), which is a type of glycoprotein [11]; (b) a membrane protein (M) that spans the membrane; and (c) an envelope protein (E) [12,13], which is a highly hydrophobic protein that covers the entire coronavirus [14,15]. For a long time, coronaviruses have been recognized as important pathogens that cause respiratory and gastrointestinal diseases in birds and mammals. Before SARS-CoV-2, six coronaviruses had been found to infect humans: HCoV-229E, HCoV-OC43, HCoV-NL63, HCoV-HKU1, severe acute respiratory syndrome coronavirus (SARS-CoV) and Middle East respiratory virus coronavirus (MERS-CoV). The first four are constraint endemic strains that cause the common cold, whereas the latter two can cause serious respiratory epidemics [16–18]. SARS is an atypical viral respiratory disease that resulted in 8098 cases and 774 reported deaths in 17 countries (9.6% fatality rate) during a large-scale outbreak in 2003 [19–21]. Fortunately, the SARS epidemic was successfully contained under joint efforts. MERS is a zoonotic respiratory infection that initially broke out in the Middle East in 2012. According to the World Health Organization records, MERS coronavirus has thus far resulted in 2494 cases of infection and 858 deaths. Based on the high prevalence and widespread distribution of coronaviruses, as well as their genetic diversity and the frequent recombination of the genome, coronaviruses pose a continuous threat to humans [22–24].

Due to the current public health emergency due to COVID-19, the U.S. Food and Drug Administration (FDA) has issued an emergency use authorization (EUA) of the experimental drug remdesivir [25,26]. However, the efficacy and safety of remdesivir remain controversial. The Japanese Ministry of Health, Labour and Welfare has also approved remdesivir as a treatment for COVID-19. In addition, the combination of α-interferon and the anti-human immunodeficiency virus (HIV) drug lopinavir/ritonavir (Kaletra®) has been used to treat COVID-19, but the evidence regarding its effectiveness remains still limited, and the drug might have toxic side effects [26–28]. Therefore, the development of highly specific and effective anti-coronavirus drugs against key viral targets, particularly SARS-CoV-2, is urgently needed and would also be of great significance for preventing and treating the recurrence of coronavirus epidemics in the future.
2. 3CL protease

The coronavirus genome has a structure with a 5'-cap and a 3'-poly-A tail and contains 6—12 open reading frames (ORFs). The first ORF (ORF 1a/b) accounts for approximately two-thirds of the genome length and can directly translate two polyproteins, pp1a and pp1ab, according to an a-1 frameshift between ORF1a and ORF1b [29,30]. The abovementioned polyproteins are then incised and functionalized into 16 non-structural proteins (nsp) by 3CL protease (3CLpro), which is also known as Mpro or papain-like protease (PLP) (Fig. 1) [31,32]. The coronavirus 3CLpro is a cysteine protease composed of approximately 300 amino acids and contains three domains [33,34]. Active 3CLpro is a homodimer that contains two promoters [35,36]. 3CLpro, which has a non-classical Cys-His catalytic dyad (Cys145 and His41) in the gap between domains I and II [37], can specifically recognize the 11 cleavage sites of nsp4-nsp16 and exhibits self-hydrolytic cleavage activity [12,38]. These functional nsp4-nsp16 released by cleavage with 3CLpro are responsible for viral genome replication and transcription, and nsp4-nsp16 also play roles in other important viral life processes, such as protein translation, cleavage, and modification [39–41]. nsp4-nsp16 also play roles in other important viral life processes, such as protein translation, cleavage, and modification [39–41].

3CLpro is highly conserved among the known coronavirus species, and several common features are shared among the different coronavirus 3CLpro substrates. From the N to the C terminus, the amino acids in the substrates are numbered as -P4-P3-P2-P1 (P1'-P2'-P3') and the cleavage site is located between P1 and P1' [40,41]. In particular, a Gln residue is almost always required in the P1 position of the substrate. Humans do not have a homologous 3CLpro, which makes 3CLpro an ideal specific antiviral target. SARS-CoV-2 and SARS-CoV are significantly different from MERS-CoV in terms of cell invasion characteristics (the S protein of MERS-CoV utilizes DPP4 as a receptor). Nevertheless, amino acid sequence alignments indicate that the similarity of the 3CLpros of SARS-CoV-2, SARS-CoV and MERS-CoV can be as high as 96.1% [42,43]. Further sequence comparisons have revealed that the 3CLpros of the three coronaviruses of SARS-CoV-2, SARS-CoV, and MERS-CoV exhibits a high degree of structural similarity and conservatism (Fig. 2) [44]. These findings indicate that 3CLpro could be used as a homologous target for the development of anti-coronavirus drugs that can inhibit the proliferation of various coronaviruses.

3. Peptidomimetic 3CLpro inhibitors

Structurally, 3CLpro inhibitors can be classified as peptoids and non-peptidomimetics, and the mechanism of action of peptide inhibitors includes two steps. Peptidomimetics that mimic natural peptide substrates initially bind to 3CLpro and form a noncovalent complex, and the warhead group, which is spatially very close to the catalytic residue of the target protein, undergoes a nucleophilic attack to catalyse the formation of cysteine-participating covalent bonds [45,46]. These warheads mainly contain Michael receptors [47,48], aldehydes [49] and different types of ketones (see Fig. 3 and Table 1) [50–52], which covalently bind to the Cys145 residue in the 3CLpro S1' pocket to exert an inhibitory effect.

Among these peptidomimetic inhibitors, the aldehyde compounds 11 and 12 and the a-ketoamide compounds 25–27 showed good inhibitory activity against the current SARS-CoV-2. Compounds 11 and 12, which as novel inhibitors designed and synthesized for SARS-CoV-2 3CLpro by Hong Liu and his colleagues [62], demonstrate excellent inhibitory activity against SARS-CoV-2 3CLpro (11: IC50 = 0.053 ± 0.005 μM, 12: IC50 = 0.040 ± 0.002 μM). Moreover, in vitro antiviral activity assays have indicated that both compounds exert potent anti-SARS-CoV-2 effects, with EC50 values of 0.53 μM and 0.72 μM, respectively, and both 11 and 12 exhibit good in vivo pharmacokinetic properties and an acceptable preliminary safety profile and have the potential to be new anti-SARS-CoV-2 preclinical candidates. Based on an analysis of the substrate binding pocket of SARS-CoV 3CLpro (PDB CODE: 2H2Z), an aldehyde was selected as the warhead in P1 that would form a covalent bond with cysteine. A detailed diagram of the interaction between compound 11 and SARS-CoV-2 3CLpro shows that the aldehyde carbonyl of 11 and the catalytic site Cys145 of SARS-CoV-2 3CLpro form a standard C–S covalent bond (Fig. 4-A). The oxygen atom of the aldehyde group forms a hydrogen bond with the backbone of the Cys145 residue at the S1' site, which is crucial for stabilizing the binding conformation. The (S)-γ-Lactam ring at P1 is in good agreement with the S1 site, and the oxygen atom of the (S)-γ-Lactam group forms a hydrogen bond with the His163 side chain, the main chain of Phe140 and the side chain of Glu166 and also forms a hydrogen bond with the NH group of the (S)-γ-Lactam ring. The cyclohexyl part at the P2 position can be inserted into the S2 position and stacks with the imidazole ring of His41. The indole group at the P3 position is exposed to the solvent (S4 site) and forms a hydrogen bond with Glu166. Interestingly, multiple water molecules (named W1–W6) play important roles in the binding of 11: W1 interacts with the amide bond of 11 through hydrogen bonding, whereas W2–W6 form a few hydrogen bonds with the aldehyde group of 11 and the residues Asn142, Gly143, Thr26, Thr25, His41 and Cys44, which contribute to the stability of the binding pocket of 11. The binding mode of compound 12 is very similar to that of 11 (Fig. 4-B). The difference in their binding modes might be due to the 3-fluorophenyl at the P2 position of compound 12. The side chains of the residues His41, Met49, Met65, Val186, Asp187 and Arg188 interact with the aryl group through hydrophobic interactions, and the side chain of Glu189 stabilizes 3-fluorophenyl via additional hydrogen bonding.
Rolf Hilgenfeld et al. previously revealed that the peptidomimetic α-ketoamide inhibitor 24 serves as a broad-spectrum inhibitor of the 3CL proso of β-coronaviruses, α-coronaviruses and enteroviruses [61]. Compound 24 exhibits a low EC50 for SARS-CoV and a number of enteroviruses in different cell lines (EC50 < 5 μM); notably, the EC50 of MERS-CoV in Huh7 cells is 400 pM. The lead 24 has been subjected to various structural modifications [63]. To improve its half-life in plasma, compound 24 was modified by hiding the P3–P2 amide bond on the pyridone ring (Fig. 5, green circle), which is expected to prevent off-target contacts and the cleavage of this bond by other cellular proteases. In addition, to enhance the solubility of 24 in plasma, the hydrophobic cinnamyl was replaced by a low-hydrophobic Boc group (Fig. 5, red circle), which produced 25. Moreover, the cyclohexyl at P2 of 25 was substituted for the smaller cyclopropyl (Fig. 5, blue circle) to render 26, which might show enhanced antiviral activity against the β-coronaviruses of clade b (SARS-CoV-2 and SARS-CoV). However, compound 27, which was obtained by removal of the Boc group of 26, was almost inactive (Fig. 5, purple circle), which indicated that the hydrophobic group is necessary for crossing the cell membrane and binding to viral 3CLpro. A pharmacokinetics study demonstrated that 4 h after its subcutaneous administration, the lung tissue concentration of 26 is approximately 13 ng/g. The lung tropism of 26 was a favourable target organ aggregation characteristic because COVID-19 and other coronaviruses mostly affect lung tissue. As a complementary route of administration, 26 can also be nebulized with an inhalation device at 3 mg/kg. Even 24 h after its administration, the concentration of 26 in lung tissue remains at 33 ng/g. A mouse lung drug inhalation model showed that 26 is well tolerated without adverse reactions, which indicates that inhalers might be a suitable method for the administration of 26.
The other peptidomimetic inhibitors shown in Fig. 3 and Table 1 were described in detail in a previous review by Thanigaimalai Pillaiyar et al. [64].

4. Nonpeptidic 3CL\textsuperscript{pro} inhibitor

4.1. Decahydroisoquinoline and octahydro-isochromene derivatives

Inspired by the interaction of the peptide inhibitor \textit{28} between S1 and S2 of SARS-CoV 3CL\textsuperscript{pro}, Shimamoto Yasuhiro et al. [65] designed and synthesized a series of competitive SARS-CoV 3CL\textsuperscript{pro} inhibitors (compounds \textit{29a}-\textit{29d}, Fig. 6) with a decahydroisoquinoline fused ring scaffold. All synthetic decahydroquinoline inhibitors exhibited moderate to significant inhibition of SARS 3CL\textsuperscript{pro}. According to X-ray crystallography (PDB CODE: 4TWY, Fig. 7), the fused ring structure of dehydroquinoline occupies most of the space in the S2 pocket. X-ray crystallography analyses have confirmed that the decahydroisoquinoline inhibitor is located in the fissure of the active centre of 3CL\textsuperscript{pro}, similar to the results obtained with the high-efficiency peptide-aldehyde lead compound. The decahydroisoquinoline scaffold was inserted into a large S2 pocket and filled most of the pocket space. As expected, the imidazole at the P1 site was inserted into the S1 pocket. These interactions effectively fixed the terminal aldehyde in the fissure of the active centre, and the new scaffold thus closely fit the active site.

| IC\textsubscript{50} | \textbf{R} | \textit{3S,4aR,8aS} | \textit{3R,4aS,8aR} |
|---------------------|---------|-------------------|-------------------|
| \textit{29a} | 108 \textmu M | 240 \textmu M |
| \textit{29b} | 240 \textmu M | |
| \textit{29c} | 63 \textmu M | 175 \textmu M |
| \textit{29d} | | |

Fig. 6. Novel decahydroisoquinoline derivatives that serve as SARS-CoV 3CL\textsuperscript{pro} inhibitors.
to the 3CLpro. Acyl groups on nitrogen atoms in decahydroisoquinoline scaffolds are located on the surface of 3CLpro, where additional interactions might occur with 3CLpro. These interactions effectively fixed the terminal aldehyde tightly at the active site, resulting in a novel decahydroquinoline scaffold that cooperates closely with 3CLpro. To evaluate the effect of the configuration on the dehydroisoquinoline scaffold, the IC₅₀ values of trans-decahydroisoquinolin diastereomers (29a vs 29b) or N-4-bromo benzoyl derivatives (29c vs 29d) have been compared, and the results clearly showed that the (4aR,8aS) isomer is more potent than the (4aS,8aR) isomer.

Based on the abovementioned findings, Shimamoto Yasuhiro et al. performed further structural modifications, and an octahydro-isochromene scaffold was selected as a new type of hydrophobic fused ring (Fig. 8). An alkyl or aryl substituent was also introduced to the 1-position of the octahydro-isochromene scaffold. The effects of the configuration of the fused ring structure and those of various substituents on the inhibition of SARS 3CLpro were evaluated. Sharpless-Katsuki asymmetric epoxidation and Sharpless asymmetric dihydroxylation were employed to synthesise the octahydro-isochromene moiety. Introduction of (S)-2-amino-3-imidazolyl propanal (His-al) at the P1 site and the substituent at the 1-position was achieved through successive reductive amination reactions. N-butyl (30), isobutyl (31), allyl (32) and benzyl (33) were introduced at the 1-position, and the IC₅₀ value for SARS 3CLpro indicates that the n-butyl substituent is expected to form a certain interaction with the protease. The stereochemical effect of the octahydro-isochromene scaffold was also investigated, and the results showed that the specific (1S,3S) configuration of 35 can orient imidazole and the warhead aldehyde at the P1 site to the corresponding 3CLpro pockets [66] (see Fig. 9).

4.2. 3CLpro inhibitor with a 3-pyridyl or triazole moiety

Jacobs et al. [46] conducted a high-throughput screening of National Institute of Health (NIH) molecular libraries

![Fig. 7. Crystal structure of SARS-CoV 3CLpro superimposed with 29a, 29b and 29c (PDB code: 4TWY).](image)

![Fig. 8. Octahydro-isochromene scaffold of SARS 3CLpro inhibitors.](image)
(approximately 293,000 compounds) to find hits of 3CL\textsuperscript{pro} inhibitors. The analysis of a dipeptide compound library identified 39 (Fig. 10-A), which had an IC\textsubscript{50} less than 10 \textmu M and was thus considered an exceptionally good candidate. Thus, a series of 3-pyridyl derivatives were subsequently optimized based on hit 39, and the resulting compounds 40a (IC\textsubscript{50} = 2.2 \textmu M) and 40b (IC\textsubscript{50} = 2.1 \textmu M) exhibited compelling inhibitory activity against SARS-CoV 3CL\textsuperscript{pro}. The X-ray crystal structure of (R)-40a combined with SARS-CoV 3CL\textsuperscript{pro} (Fig. 11) demonstrated that (R)-40a preferentially occupied the S1’-S3 3CL\textsuperscript{pro} subpockets. According to the identified binding mode, tert-butyl amide occupies the S3 pocket, the tert-butyl anilido group occupies a deep S2 pocket, and the 3-pyridyl group occupies the S1 pocket.

To further clarify the SAR of the lead compound 40a, the P1–P3 framework was maintained consistent, whereas a library of five-membered aromatic heterocycles was synthesized through alterations in the P1\textsuperscript{0} position (Table 2, 41a-41f). Among the resulting compounds, imidazole (41c, IC\textsubscript{50} = 6 \textmu M) and 5-chlorofuran (41e, IC\textsubscript{50} = 5.2 \textmu M) substituted analogues were found to be the most potent. A subsequent study of P1 replacements was performed to identify alternative hydrogen bond-acceptor groups that might engage His163 while retaining the 2-furyl amide P1\textsuperscript{0} group. Among the six-membered \pi-excessive heterocycles examined (42a-42c), pyridazine (42a) and pyrazine (42b) were well tolerated. Furthermore, chiral stationary-phase supercritical fluid chromatography (SFC) was applied to separate 40a enantiomers (Fig. 10-B), and

![Fig. 9. 38 and its binding pocket with SARS 3CL\textsuperscript{pro}.](image)

![Fig. 10. (A) Primary SAR study of the furyl amide hit compound 39. (B) (R)-40a and (S)-40a.](image)
highly specific inhibition was obtained with a single stereoisomer (R)-40a (ML188), which exhibited an IC50 of 1.5 ± 0.3 µM.

Further screening revealed that a class of noncovalent benzo-triazole inhibitors from the NIH Molecular Libraries Probe Production Centers Network (MLPCN) exhibited improved biological activity [68]. Among these compounds, compound 43 substantially inhibited SARS-CoV 3CLpro (IC50 = 6.2 µM).

According to X-ray crystallography (PDB code: 4MDS, Fig. 12), rearrangement of the Gln189 and Met49 residue side chains forms the diamide 43, which exhibits an induced-fit binding site. This induced-fit binding site accommodates the syn N-methyl pyrrole and anilido acetamide moieties of the inhibitors within the S2–S4 and S2–S1′ subpockets, respectively. In addition to the P2–P4 and P2–P1′ groups, 43 partially occupies the S3 subpocket with a terminating 2-methylbutylamide. Moreover, Cys145 and benzo-triazole N-(2) form a key hydrogen bond near the catalytic centre. Other hydrogen bond interactions are found near the catalytic site of His163 and benzotriazole N-(3), and the main chain Glu-166 NH shows an obvious interaction with the central acetamide oxide.

As a promising hit, the template compound 43 has been subjected to intense derivatization, including P1 modifications, P2–P1′ exploration and P3 truncation (Fig. 13). First, the failure of the alteration of P1 to benzimidazole (44a-44c) indicated a strict substituent requirement for the 1,2,3-triazole unit. Comparatively, 4-phenyl-1,2,3-triazolium 44f exhibited effective inhibition (IC50 = 11 µM), and unsubstituted triazole 44d and trimethyl silyl triazole 44e were ineffective, which demonstrated the importance of maintaining a proper aromatic ring in the P1 sub pocket during the optimization. Second, acetamide at the P2–P1′ region was exchanged with cyclic and acyclic amide congeners to render a series of analogues with IC50 values below 10 µM, and the i-propyl 45b and cyclobutyl 45d amide derivatives exhibited compelling activity with IC50 values less than 5 µM. Furthermore, researchers performed fragment truncation at the P3 position to minimize pharmacophores and thereby reduce the overall redundant group and molecular weight, which could improve the physical and chemical properties as well as the ligand binding efficiency. Satisfactorily, the truncated amides 46 exhibit comparable activity to the well-designed diamide counterparts 45 (see Fig. 12 for 45a-45d vs 46a-46d). Karypidou et al. [69] prepared a novel library of fused 1,2,3-triazole [4,5-c] pyridine derivatives, and among these, 47–51 exhibited good antiviral properties against human coronavirus 229E (Table 3).

### 4.3. 3CLpro inhibitor with a piperidine moiety

Based on an analysis of the optimization of the lead GC376 (52), addition of an aldehyde bisulphite at the P1′ position is necessary for the reaction with the active site Cys148 to generate tetrahedral hemithioacetal. Moreover, the γ-lactam ring at the P1 position and the Leu side chain at the P2 position should be retained and might occupy the S1 and S2 hydrophobic pockets, respectively. Additionally, extending the benzyloxy “cap” to the chlorine-substituted phenyl-ethanol fragment yields GC813 (53), and its lower IC50 value can be attributed to an extended conformation and might orient the phenyl ring towards the hydrophobic S4 pocket. As a common privileged scaffold in drug design and discovery, the piperidine moiety is a good design element that can exhibit good interactions with numerous classes of proteins, which would result in optimal pharmacological activity and PK properties [70]. Thus, introducing the high-affinity

| Compound | P1′ | 3CLpro IC50 (µM) | Compound | P1 | 3CLpro IC50 (µM) |
|----------|-----|-----------------|----------|-----|-----------------|
| 41a      |     | 39              | 42a      |     | 10              |
| 41b      |     | 50              | 42b      |     | 5.5             |
| 41c      |     | 6               | 42c      |     | 45              |
| 41d      |     | 47              | 41      |     | 5.2             |
| 41e      |     | 5                | 41f      |     | 75              |
piperidine moiety into the peptoid scaffold yields a series of structurally novel inhibitors (Table 4, 54a-54f). The piperidine-based design strategy is an effective tactic for rendering a dipetidyl inhibitor capable of engaging in optimal binding interactions with all four S1–S4 subsites, and the resulting inhibitors have a lower molecular weight and a reduced peptidyl character compared with the tetrapeptidyl inhibitor, which is expected to display enhanced solubility and PK liabilities. Gratifyingly, 54b and 54d, which are representative aldehyde bisulphite compounds, display potent MERS-CoV inhibitory activities with low cytotoxicity (CC_{50} > 100 μM).

4.4. Unsymmetrical aromatic disulphides

Unsymmetrical aromatic disulphide compounds are a class of inhibitors that exert significant inhibitory effects on SARS 3CL\textsuperscript{pro} [71]. These new chemical entities display excellent IC\textsubscript{50} values in the range of 0.516–5.95 μM (Fig. 14, compounds 55–59). Preliminary studies have indicated that these disulphides are reversible and competitive inhibitors. Among these disulphides, the representative compound 55 binds to SARS-CoV 3CL\textsuperscript{pro} via multiple hydrogen-bonding and hydrophobic contacts. Phe140, Leu141, His163, Met165, Glu166 and His172 form hydrophobic interactions with 55, whereas Asn142, Gly143 and Cys145 form intermolecular hydrogen bonds with 55 (Fig. 15).

4.5. Serine derivatives

To develop nonpeptidic inhibitors that interact with the P1, P2 and P4 sites of 3CL\textsuperscript{pro}, a new series of serine derivatives were designed by Kenichi Akaji et al. based on the tetrapeptide aldehyde Ac-Thr-Val-Cha-His-H (60, IC\textsubscript{50} = 98 nM) and Bai’s bis-cinnamoyl inhibitor (IC\textsubscript{50} = 10.6 μM) [72,73]. First, imidazole, cyclohexyl, and hydroxyl groups, which were previously reported in the literature and exhibit potent biological activity, were linked to L-serine for the design of serine derivatives (61–62), as shown in Fig. 16. However, compared with peptide inhibitor 83, these optimized groups did not provide good coverage of the substrate-recognition pocket of 3CL\textsuperscript{pro} (PDB code: 3AW1), and the different binding modes of peptide inhibitors and non-peptide inhibitors with 3CL\textsuperscript{pro}s lead to changes in the interactions between these groups and the corresponding pocket [74]. It was hypothesised that the cyclohexyl group would occupy the S2 pocket of 3CL\textsuperscript{pro}, but contrary to the expectations, molecular mechanics calculations and docking simulations indicated that the cyclohexyl group of serine derivatives (61, 62) must occupy the S1 pocket of 3CL\textsuperscript{pro}. Thus, the imidazole and hydroxyl groups of 61 and 62, which are expected to interact with the S1 and S4 pockets, were not effective and thereby reduced the interaction between the inhibitor and 3CL\textsuperscript{pro}. In addition, Bai’s inhibitor 63 is located deep inside the S1, S1 and S2 pockets and exhibits appropriate cinnamoyl functionalities [75]. Therefore, benzoyl and aniline groups were used to molecularly dock with serine derivatives to obtain 64. In addition, reasonable structural transformations of the serine derivative and hybrids constructed with other functionalities were investigated. Virtual screening using GOLD software indicated that N-cinnamoyl derivatives with benzoate, such as 64 and 65, are suitable substructures.

Based on the binding of the substrate recognition pocket of the SARS 3CL\textsuperscript{pro} R188I mutant (PDB code: 3AW1), the isoserine skeleton was found to exhibit a more reasonable interaction with the mutant 3CL\textsuperscript{pro} resulting in the isoserine derivative (R)-66, which might be obtained by replacing the amine group at the α-position and adding a hydroxy group at the β-position of 65. The docking simulation of (R)-66 with SARS 3CL\textsuperscript{pro} revealed a hydrophobic space on the S2 pocket of the R188I mutant protease. Compared with hydrophobic functional groups (such as alkanes, cycloalkane and aromatic rings), the phenyl group was more suitable for insertion into the S2 pocket of the R188I mutant protease; therefore, (2R,3S)-phenylisoserine (PIS) derivative 67 was obtained and selected as a candidate compound. A SAR study of the PIS derivative and the corresponding S1′ pocket revealed that the inclusion of a cinnamic derivative (68a, 68b) or a phenyl propionate derivative (68c) at the P1′ position elevated the inhibitory activity, with IC\textsubscript{50} values ranging from 65 to 75 μM (Fig. 17). In addition, cyclohexyl rings are essential to the P1 function of PIS scaffolds, whereas the cinnamyl functional group at P4 can effectively maintain the inhibitory strength.

4.6. Pyrazolone and pyrimidines

Based on the 1,3,4,5-tetraaryl-substituted pyrazole 69 identified through high-throughput screening, a series of 1,3,4-triple substituted pyrazolinone compounds were designed and synthesized as SARS-CoV 3CL\textsuperscript{pro} inhibitors. Among the resulting compounds (Fig. 18), 70–73 exerted strong inhibitory effects on SARS-CoV 3CL\textsuperscript{pro}, with IC\textsubscript{50} values of 5.5, 10.8, 6.8 and 8.4 μM, respectively, and favourably, 73 could also effectively inhibit coxsackievirus B3 3CL\textsuperscript{pro} [76]. Po-Huang Liang et al. further synthesized a series of analogues by grafting the neumaminidase (NA) inhibitor phenyl furan moiety into a 1,3,4-triple substituted pyrazolinone nucleus [77]. Among the resulting series, compounds 74d–74f showed comparable inhibitory activity against SARS and MERS 3CL\textsuperscript{pro}s. In addition to the catalytic residue Cys145, the S1 subsite of 3CL\textsuperscript{pro} also included another important component, the oxyanion hole. This component is formed by the interaction of the C-terminal carboxylic acid of the conserved Gin with Gly143, Ser144 and Cys145, which stabilizes the transition state during proteolysis. Docking studies have indicated that the carboxylates present at the A or D ring are critical for disrupting the stability of the oxyanion hole in 3CL\textsuperscript{pro}. Further SAR studies have shown that the pharmacophores phenyl at R\textsubscript{1} (74a vs 74b) and a carboxylate at either R\textsubscript{1} or R\textsubscript{2} (74c vs 74d) are essential for the activity (Fig. 18). Because the modification of rings A and B is tolerated well, the D ring can be further altered to enhance the activity of the compounds.
Another series of 2-(benzylthio)-6-oxo-4-phenyl-1,6-dihydropyrimidines (75a-75f) also showed encouraging results as new anti-SARS hits [78]. The cytotoxicity of the test compounds was assessed using the MTT assay, and all the compounds were devoid of cytotoxicity. Further SAR studies revealed that compound 75c, which has a nitro at the C-4 position, is the most potent.
inhibitor of SARS-CoV 3CLpro (IC50 = 6.1 μM). The moderate electron-withdrawing substituent at R1, such as chloro, in compounds 75c and 75d improved the inhibitory activity compared with the presence of electron-donating groups, such as methyl and methoxy groups (as shown in Table 5). Molecular docking results have illustrated (docking study of 75c with PDB code: 1UK4) that the distance between the NH of the pyrimidine ring and the oxygen atom of Glu-166 was constrained by 2.0 Å. The orientation of the ligand has a nitro phenyl group situated in the S1 pocket, and the nitro group points towards the surface of the protein. The oxygen of the nitro group forms a hydrogen bond with Gly143 and Cys145, and the chlorophenyl ring fits into the S2 pocket and forms hydrophobic interactions with Met49 and Gln189.

4.7. Natural product derivatives

4.7.1. Flavonoids, biflavonoids and chalcones

Quercetin (76), epigallocatechin gallate (77) and gallotannin gallate (78, GCG) also show mild inhibitory effects against SARS-CoV 3CLpro, with IC50 values of 73 μM, 73 μM and 47 μM, respectively (Fig. 19). In addition, 78 exhibits competitive inhibition towards 3CLpro, with a Ki value of 25 μM. According to the results from a docking analysis, the galloyl acyl moiety at the 3-OH position of compound 78, which occupies the S1 pocket, is essential for inhibitory activity against 3CLpro [79]. A series of inhibitors were isolated and purified from the leaves of Torreya nucifera (Fig. 19).

Another series of chalcones (Figs. 19, 83–85) isolated from Angelica keiskei were evaluated in terms of their anti-SARS 3CLpro activity. Chalcone 84, which contains perhydroxyl groups, exhibited the most potent inhibitory activity against 3CLpro, with an IC50 value of 11.4 μM. A detailed ligand-protein mechanistic analysis indicated that the chalcones exhibited competitive inhibition with SARS-CoV 3CLpro [81].
4.7.2. Isatin derivatives

Previous studies have shown that isatin and its derivatives have a wide range of antiviral and antibacterial activities [82–84], including anti-HIV virus [85,86], anti-hepatitis C virus (HCV) [87], anti-mycobacterium tuberculosis and anti-pathogenic activities [88,89]. In addition, isatin derivatives are good candidates for the development of anti-coronavirus drugs [90]. For anti-coronavirus drug discovery, a series of synthetic 5-sulfonyl isatin derivatives were designed and synthesized.

Fig. 16. Design scheme of serine derivatives 64 and 65.

Fig. 17. Evolution of phenyl isoserine derivatives 68a, 68b, and 68c from serine derivatives.
(86–92) were reported as noncovalent SARS MPRO inhibitors [91]. These isatin derivatives inhibited SARS-CoV 3CLPRO at the low micromolar range, and 86 (IC50 = 1.04 μM) was found to be the most potent. SAR studies revealed that the piperidin sulfonyl-substituted compounds 86–89 exerted a more significant inhibitory effect against 3CLPRO (IC50 < 5 μM) than the piperazine sulfonyl-substituted isatins 90–92. Among the former, the 4-methyl piperidin sulfonyl (87, IC50 = 1.18 μM) and 2-methyl piperidin sulfonyl (88, IC50 = 2.25 μM) isatin derivatives were identified as the optimal candidates.

### 4.7.3. Terpenoid derivatives

A screening of natural products for the identification of antiviral MPRO inhibitors revealed that tanshinone-type diterpenes (compounds 93–99) derived from Salvia miltiorrhiza are selective inhibitors of SARS-CoV 3CLPRO and PLpro [92]. With the exception of cryptotanshinone (96), the other isolated tanshinones exerted a dose-dependent inhibitory effect but no time-dependent effect against 3CLPRO. The activity of 93–99 against 3CLPRO ranged from 14.4 to 89.1 μM. Further SAR study revealed that subtle differences in the substituents and stereo configuration can substantially affect the inhibitory activity. Specifically, the presence of a naphthalene moiety in the diterpene quinolone backbone appeared to improve the inhibition of 3CLPRO in compared with that obtained with dimethyl-substituted tetralin (97 and 98 vs 93 and 96). In addition, the dihydrofuran group (96) on ring A of cryptotanshinone reduced the inhibitory activity by two-fold compared with that of tanshinones (93–95) containing a furan group.

Additionally, celastrol (100), pristimerin (101), tingenone (102), and iguesterin (103) were isolated from Tripterygium regelii and showed favourable competitive inhibitory activities against SARS-CoV 3CLPRO with IC50 values of 2.6, 9.9, 5.5 and 10.3 μM, respectively [93]. Dihydrocelastrol (104) was synthesized by hydrogenation under a palladium catalyst, but its 3CLPRO inhibitory activity on SARS 3CLPRO was relatively weak. Further SAR research indicated that a quinone-methide moiety in the A ring and a more hydrophobic E ring could promote inhibitory activity against 3CLPRO.

### 5. Discussion and perspectives

As the cases of SARS-CoV infections continue to rise, the development of effective drugs and vaccines for the targeted treatment of COVID-19 is becoming increasingly urgent. Among the few available targets for anti-coronavirus drug development, 3CLPRO, which is a key protein involved in the replication and transcription of coronaviruses, has become an important and
relatively mature drug target in anti-coronavirus drug research. In addition, the SASR-CoV-2 3CL\textsuperscript{pro} crystal structure (PDB code: 6LU7) is the first non-structural functional protein of SASR-CoV-2 that has a confirmed conserved structure compared with those of SASR and MERS 3CL\textsuperscript{pro}s. Thus, broad-spectrum coronavirus 3CL\textsuperscript{pro} inhibitors are particularly suitable for the treatment of current and future coronavirus epidemics. The present article reviews the research progress on coronavirus 3CL\textsuperscript{pro} inhibitors discovered from various sources over the past 10 years (2010–2020), including synthetic peptidomimetic and nonpeptidic inhibitors and natural product derivatives, and attempts to provide a complete description of the structural characteristics of 3CL\textsuperscript{pro} inhibitors, including details on their binding modes and other related information.

Herein, the structural characteristics, binding modes and SARs of recent coronavirus 3CL\textsuperscript{pro} inhibitors are fully described. The warhead groups of peptidomimetic inhibitors mainly include aldehydes, ketones and different types of Michael receptors. These covalent irreversible inhibitors mainly utilize warhead functional groups to covalently bond with Cys145 residues in the 3CL\textsuperscript{pro} S1\textsuperscript{'} pocket and thereby exert relatively durable inhibitory effects. The published studies have shown that covalent irreversible 3CL\textsuperscript{pro} inhibitors exhibit significantly improved antivirus activity, and some
inhibitors can even achieve effects at nanomolar levels. However, covalent inhibitors exhibit potential off-target problems and toxic side effects. Although the recent studies on peptidomimetic inhibitors are fewer than those that investigated nonpeptidic inhibitors, the aldehyde compounds 11 and 12 and α-ketoamide compounds (25–27), which are among the recently reported peptidomimetic 3CL\textsuperscript{pro} inhibitors, exhibit excellent inhibitory activity against SARS-CoV-2. Inhibitor 11 is one of the most effective inhibitors among the aldehyde peptide series. Thus, the toxicity of inhibitor 11 over a 7-day period has been studied at different doses, specifically at dosing levels of 2, 6, and 18 mg/kg on SD rats and at a dose range of 10–40 mg/kg on beagle dogs, and all the tested animals showed significant toxicity after the inhibitor was administered once a day (QD) via intravenous drip. Therefore, 11 might be a good candidate for further COVID-19 clinical research. Coincidentally, the pharmacokinetic characteristics of compound 26 indicated obvious lung affinity, and this compound is suitable for administration via inhalation. Therefore, the pyridone-containing compound 26 might become another lead for further COVID-19 pandemic research.

Correspondingly, noncovalent reversible 3CL\textsuperscript{pro} inhibitors mainly exhibit weak reversible binding (such as hydrogen bonds, van der Waals forces, and hydrophobic forces) with the amino acid residues in the S1, S2, and S4 pockets, which sometimes includes the catalytically active Cys145 in the S1\textsuperscript{'} pocket. This weak reversible binding could result in avoidance of the off-target risk and toxicity of irreversible inhibitors, and thus, these inhibitors might be suitable for long-term administration. Among the nonpeptidic reversible inhibitors, 55–59, which contain a piperidine moiety, and 54a–54f, which contain unsymmetrical aromatic disulphides, demonstrate excellent inhibitory activity. Some natural products and derivatives, such as isatin [94], flavonoids, and tanshinone, might also be good candidates for the development of anti-coronavirus drugs. Specifically, 46a, 54a, 74d and 75c are noncovalent SARS-CoV 3CL\textsuperscript{pro} inhibitors with a medium molecular weight and good antiviral activity and can potentially be utilized as lead templates for further drug design and screening.

However, 3CL\textsuperscript{pro} noncovalent inhibitors also have some shortcomings, such as drug effects that are not strong and/or durable, which means that these noncovalent inhibitors would need to be administered at high dosages or multiple times. Noncovalent inhibitors can also result in the emergence of resistance after their long-term administration. Based on a review of the advantages and disadvantages of both covalent and noncovalent inhibitors of 3CL\textsuperscript{pro}, we recommend that reversible covalent inhibitors of 3CL\textsuperscript{pro} constitute a new research direction. Specifically, the Michael warhead can be replaced by cyano (or trifluoromethyl), which might result in the formation of a reversible covalent bond with the Cys145 residue, which is unique to the coronavirus 3CL\textsuperscript{pro} S1\textsuperscript{'} pocket, and this binding can potentially reduce the “off-target” risk and toxic side effects while enhancing the efficacy [95–98].

---

**Fig. 20.** Illustration of PROTACs targeting the degradation of 3CL\textsuperscript{pro} and thereby inhibiting coronavirus assembly and replication.
Further analyses of the previous studies on 3CL\textsuperscript{pro} inhibitors in association with the booming research on PROTACs \cite{99,100} have led to the emergence of the following drug development ideologies. PROTAC technology can be used in the design of anti-coronavirus drugs that induce the intracellular degradation of functional nsp5 of exogenous viruses. The principle of PROTAC technology involves the use of a bifunctional small molecule to link the target protein and the E3 ligase in the cell such that the target protein is ubiquitinated, and the ubiquitinated protein is then recognized by the proteasome, which leads to degradation of the target protein \cite{101}. To date, various endogenous proteins, such as BTK, PARP1, HDAC6, AR, ER, BET, BRD4, BRD9, RIPK2, TBK1, Sir2, CDK9, p38\alpha, pirin, c-Met, EGFR, FAK, and FLIT3, have been reportedly degraded using PROTAC technology \cite{102–106}. However, the application of PROTAC technology for the degradation of foreign proteins (such as viral proteins) remains in its infancy. To date, only the NS3/4A protease degrader DGY-08-057 of HCV has been reported, and its antiviral activity and resistance characteristics are significantly superior to those of the traditional drug telaprevir \cite{107}. Thus, we propose that the existing 3CL\textsuperscript{pro} inhibitors can be combined with PROTAC technology to develop coronavirus 3CL\textsuperscript{pro} PROTACs. These PROTAC degraders could exhibit the advantages of both occupancy-driven PROTAC inhibitors and those of event-driven PROTACs: low-dose exposure would result in multiple rounds of 3CL\textsuperscript{pro} degrada-
tion and would avoid the intracellular accumulation of 3CL\textsuperscript{pro} in infected cells. These procedures would completely block the biological function of coronavirus 3CL\textsuperscript{pro} and its downstream viral proteins and would therefore inhibit the assembly and replication of the coronavirus in infected cells (shown in Fig. 20). Reversible covalent PROTACs for 3CL\textsuperscript{pro} have been designed and synthesized in our laboratory for further screening, and we expect that these in-
hibitors will overcome the shortcomings of traditional 3CL\textsuperscript{pro} in-
hibitors and take advantage of the degradation effects of PROTACs.
