Two new natural compounds, \((1\,R,2\,E)-2-(6\text{-hydroxyhexylidene})\text{cyclopropyl-}\beta\text{-d-glucopyranoside} (1)\) and \((6\,E)-6-[2\,(2\,R)-2-(\beta\text{-d-glucopyranosyloxy})\text{cyclopropylidene} \text{hexanoic acid} (2)\), glucosides of a very rare methylidenecyclopropane alcohol, as well as two known glycosides of phenolic acids, namely \(4\text{-O-}\beta\text{-d-glucopyranosylcaffeic acid} (3)\) and \((E)-4\text{-O-}\beta\text{-d-glucopyranosylcoumaric acid} (4)\), and methyl \(\alpha\text{-fructofuranoside} (5)\) have been isolated (Fig. 1).

The characterization of 1, a white crystalline substance, was achieved by means of mass spectrometry and extensive 1D- and 2D-NMR experiments. From the ESI mass
spectra, a molecular weight of 318 Da was deduced. Using flow injection analysis (FIA), the mass spectrum in the negative-ion mode displayed the \([M-H]^-\) ion peak at \(m/z\) 317, whereas in positive-ion mode not only the \([M+H]^+\) ion peak at \(m/z\) 319, but also the \([M+NH_4]^+\) and \([M+Na]^+\) peaks at \(m/z\) 336 and 341, respectively, were detected. Product ion peaks were recorded with MS/MS in both, the positive- and negative-ion mode at various collision energies. The \([M+H]^+\) ion showed mainly fragmentation of the glycosidic bond to yield the \(Y_0^+\) ion (\(m/z\) 157) and the \(Z_0^+\) ion (\(m/z\) 139). The \([M-H]^-\) ion produced the complementary \(C_1^+\) and \(B_1^+\) fragment ions (\(m/z\) 179 and 161, resp.), as well as the \(a_2A^-\) and the \(a_3A^-\) ions (\(m/z\) 119 and 89, resp.), resulting from cross-ring cleavage of the hexose. The HR-ESI-MS revealed a molecular weight of 318.3618 in accordance with the molecular formula \(C_{15}H_{26}O_7\).

In the NMR experiments, the sugar part was easily characterized as a \(\beta\)-glucopyranose. The aglycon showed mainly signals for \(\text{CH}_2\) groups in the aliphatic region, one \(\text{C}==\text{C}\) bond \(\text{CH}\) signal, and an additional \(\text{CH}\) signal at 4.18 ppm in the \(^1\text{H}\)-NMR. The \(^{13}\text{C}\)-NMR additionally showed the resonance of a quaternary olefinic \(\text{C}\)-atom at 123.9 ppm. The structure of the aglycon could be identified as a 2-(6-hydroxyhexylidene)cyclopropanol moiety (for the structure, see Fig. 1), linked glycosidically with glucose via the alcohol attached to the cyclopropane ring. This result is based on the characteristic \(^1\text{H}\)- and \(^{13}\text{C}\)-NMR chemical shifts (Table 1) of the cyclopropane signals together with rather large \(^1\text{H}\),\(^{13}\text{C}\) one-bond coupling constants, namely 188.2 Hz for \(\text{H}==\text{C}(9')\), and 163.9 and 161.0 Hz for the \(\text{CH}_2(8')\), respectively [3]. The observed \(\text{C}==\text{C}\) stretching frequency of 1775 cm\(^{-1}\) in the IR spectrum of 1 is in accordance with published data of similar methylidenecyclopropane structures [4]. Numerous HMBCs established all the necessary connectivities, e.g., the interglycosidic linkage by a cross-peak from \(\text{H}==\text{C}(1)\) to \(\text{C}(9')\), or correlations within the aglycon from \(\text{H}==\text{C}(6')\) to the \(\text{C}(9'), \text{C}(8'), \text{C}(5'), \text{C}(4')\), and from \(\text{H}==\text{C}(1')\) to \(\text{C}(2')\) and \(\text{C}(3')\), respectively (Fig. 2). NOESY Cross-peaks from \(\text{CH}_2(5')\) to \(\text{CH}_2(8')\) within the cyclopropanol revealed the geometry of the \(\text{C}==\text{C}\) bond. Attached to the \(\text{C}==\text{C}\) bond is a \(\text{C}_5\) aliphatic chain terminated by an alcohol function. From all data above, the structure of compound 1 was established as (2\(E\))-2-(6-hydroxyhexylidene)cyclopropyl-\(\beta\)-\(D\)-glucopyranoside.
Compound 1 additionally was crystallized in a solvent mixture of MeOH and Et₂O. X-Ray-diffraction analysis established the relative configuration of the stereogenic centre in the methylenecyclopropyl-alcohol moiety relative to glucose (Fig. 3). The absolute configuration of the glucose was established after hydrolysis, reaction of the sugar with chiral (−)(−)-(R)-butan-2-ol, trimethylsilylation, and GC/MS analysis of the resulting derivative [5][6], and, consequently, the absolute configuration of the aglycone was deduced as (R).

The ESI-MS of compound 2 displayed the \([M−H]^−\) ion peak at \(m/z\) 331 in the negative-ion mode, and the \([M+H]^+\), \([M+NH_4]^+\), and the \([M+Na]^+\) ion peaks at \(m/z\) 333, 350, and 355, respectively, in positive-ion mode, providing a molecular weight of 332 Da. Due to the presence of the carboxylic acid group in 2, stable Y₀ and Z₀ fragment ions (\(m/z\) 169 and 151, resp.) could be detected upon MS/MS of the \([M−H]^−\) ion. In addition, peaks of the cross-ring fragment ions \(^{13}A^−\) and \(^{15}A^−\) at \(m/z\) 119 and 89.

Table 1. \(^1\)H- (600.13 MHz) and \(^{13}\)C-NMR (150.92 MHz) Data of 1 and 2 in CD₃OD (\(\delta\) in ppm; \(J\) in Hz)

| Position | 1 \(\delta\)(H) | 1 \(\delta\)(C) | 2 \(\delta\)(H) | 2 \(\delta\)(C) |

Compound 1 additionally was crystallized in a solvent mixture of MeOH and Et₂O. X-Ray-diffraction analysis established the relative configuration of the stereogenic centre in the methylenecyclopropyl-alcohol moiety relative to glucose (Fig. 3). The absolute configuration of the glucose was established after hydrolysis, reaction of the sugar with chiral (−)(−)-(R)-butan-2-ol, trimethylsilylation, and GC/MS analysis of the resulting derivative [5][6], and, consequently, the absolute configuration of the aglycone was deduced as (R).

The ESI-MS of compound 2 displayed the \([M−H]^−\) ion peak at \(m/z\) 331 in the negative-ion mode, and the \([M+H]^+\), \([M+NH_4]^+\), and the \([M+Na]^+\) ion peaks at \(m/z\) 333, 350, and 355, respectively, in positive-ion mode, providing a molecular weight of 332 Da. Due to the presence of the carboxylic acid group in 2, stable Y₀ and Z₀ fragment ions (\(m/z\) 169 and 151, resp.) could be detected upon MS/MS of the \([M−H]^−\) ion. In addition, peaks of the cross-ring fragment ions \(^{13}A^−\) and \(^{15}A^−\) at \(m/z\) 119 and 89.

\(^1\) CCDC-844491 contains the supplementary crystallographic data for this article. These data can be obtained free of charge via http://www.ccdc.cam.ac.uk/data_request/cif.
respectively, were observed again. The MS/MS measurements in the positive-ion mode revealed corresponding results.

The NMR data of compound 2 were very similar to those of compound 1. Again the sugar part was a \(\beta\)-glucopyranose with the glycosidic bond to the unusual methylidenecyclopropane alcohol. Differences were detected in the side chain: the signals for the terminal CH\(_2\)-OH group were missing, one CH\(_3\) signal was shifted to lower field, and a CO group signal at 182.9 ppm appeared in the \(^{13}\)C-NMR spectrum showing a HMBC to the afore mentioned CH\(_2\) group. Accordingly, the terminal alcohol in the alkane side chain of 1 should have been oxidized in 2 to give the corresponding carboxylic acid, \((6E)-6-[2-(\beta\text{-glucopyranosyloxy})\text{cyclopropylidene}]\text{hexanoic acid}.

Both compounds have, to the best of our knowledge, never been described in the literature, neither isolated from natural sources nor synthesized. The common characteristic structural feature of these new glycosidic compounds is the extremly rare methylidenecyclopropane alcohol as the aglycon moiety.

\(\beta\)-Glucopyranose was also determined as the sugar part in compounds 3 and 4, but their aglycons were different. Both genins are phenolic acids for which differing NMR signals in the aromatic region were observed: the \(^1\)H-NMR spin system for a trisubstituted benzene together with the \((E)\)-C=C bond revealed compound 3 as caffeic acid. On the other hand, compound 4, showing only two doublet signals, could be identified as \((E)\)-\(p\)-coumaric acid. HMBC Cross-peaks established the glycosidic linkage to the phenol in the opposite position of the conjugated acid in both compounds. On the basis of these data, 3 was identified as 4-\(O\)-\(\beta\)-d-glucopyranosylcaffeic acid and 4 as \((E)\)-4-\(O\)-\(\beta\)-d-glucopyranosylcoumaric acid (Fig. 1). Their NMR spectroscopic data corresponded to those published [7]. Compounds 3 and 4 are not very widespread in plant kingdom. They have been isolated from several ferns such as \textit{Davilla mariesii Moore}, \textit{Camptosorus sibiricus} \textit{Rupr.}, and \textit{Matteuccia struthiopteris} \textit{(L.) Tod}. [7–9]. Additionally, 4-\(O\)-\(\beta\)-d-glucopyranosylecaffeic acid (3) has been found in the Colchicaceae family [10] and \((E)\)-4-\(O\)-\(\beta\)-d-glucopyranosylcoumaric acid (4) in Fabaceae [11][12], and both only in few other plant species so far.

Compound 5 was identified as a methyl glycoside. Two CH\(_2\) groups and one quarternary C-atom indicated a ketose. The detailed NMR analysis and comparison of the \(^{13}\)C-NMR data with those in the literature [13] revealed compound 5 as methyl \(\alpha\)-fructofuranoside.
The new compounds 1 and 2 were tested for \textit{in vitro} cytotoxic activity against the colon carcinoma cell line SW480. Cell viability was assessed by a neutral red uptake assay as described in [14]. The compounds did not exhibit significant activity ($IC_{50} > 250 \text{ \mu M}$).

In conclusion, the chemical analysis of the Costa Rican tree fern \textit{Metaxya rostrata} C.Presl. yielded two new compounds, (1$R$,2$E$)-2-(6-hydroxyhexylidene)cyclopropyl $\beta$-D-glucopyranoside (1) and (6$E$)-6-[(2$R$)-2-(6-glucopyranosyloxy)cyclopropylidene]-hexanoic acid (2). Thus, for the very first time glucosides of a new natural methylidenecyclopropane alcohol were isolated. To the best of our knowledge, this methylidenecyclopropane alcohol has also never been synthesised before. In addition, two phenolic acid glycosides, 4-O-$\beta$-D-glucopyranosyleaffeic acid (3) and (E)-4-O-$\beta$-D-glucopyranosylcoumaric acid (4), and methyl $\alpha$-fructofuranoside (5) were isolated for the first time from this plant.

**Experimental Part**

\textbf{General.} Anal.-grade solvents for extraction and fractionation were obtained from VWR (A-Viena). TLC: on silica gel plates (Merck, Germany), mobile phase AcOEt/HCOOH/MeOH/H$_2$O 70:8:8:11, and detection with anisaldehyde/sulfuric acid reagent [15]. Optical rotation: Perkin Elmer Polarimeter 341. UV/VIS Spectra: Beckman DU 640 spectrophotometer. IR Spectra: Perkin Elmer FT-IR 2000 instrument in attenuated total reflection mode using a Golden Gate ATR unit. All NMR spectra were recorded on a Bruker Avance DRX 600 NMR spectrometer using a 5 mm switchable quadruple probe (QNP. $^1$H, $^{13}$C, $^{19}$F, $^{31}$P) with z axis gradients, and automatic tuning and matching accessory; $^1$H: 600.13 and $^{13}$C: 150.92 MHz. All recordings were performed in a soln. in CD$_3$OD at 298 K. Standard 1D and gradient-enhanced (ge) 2D experiments such as double quantum filtered (DQF) COSY, TOCSY, NOESY, HSQC, and HMBC were conducted as instructed by the manufacturer. Chemical shifts are referenced internally to the residual, non-deuterated solvent signal for $^1$H (0 3.31 ppm) or to the C-atom signal of the solvent for $^{13}$C (d 49.00 ppm). The analysis of the $^1$H,$^1$H coupling constants (in Hz) were supported by the program Spin-Works (provided by Kirk Marat, University of Manitoba, Canada). ESI-MS Data were acquired on a API 4000 triple quadrupole mass spectrometer (AB Sciex Instruments, Foster City, CA, USA) in both negative- and positive-ionization mode. Mass spectra were recorded over the range m/z 100–1000; scan time was 1 s. Product ions (MS/MS) were scanned from m/z 40–400 within 1 s of scan time. FIA was carried out with MeOH/aq. NH$_4$OAc 5 mmol (80:20). HR-ESI-MS Data were obtained with a Biosystems QStar (Q-TOF) instrument in ESI negative-ion mode.

\textbf{Crystallographic Structure Determination.} X-Ray diffraction measurement was performed on a Bruker X8 APEX II CCD diffractometer. Single crystal of 1 was mounted on glass fiber, coated with Paratone N oil and positioned at 35 mm from the detector. 890 frames were measured, each for 50 s over 1° scan width. The data were processed using SAINT software [16]. Crystal data, data collection parameters, and structure refinement details are compiled in Table 2. The structure was solved by direct methods and refined by full-matrix least-squares techniques. The non-H-atoms were refined with anisotropic displacement parameters, while the H-atoms were placed at geometrically calculated positions and refined as riding atoms in the subsequent least-squares model refinements. The isotropic thermal parameters were estimated to be 1.2 times the values of the equivalent isotropic thermal parameters of the atoms to which H-atoms were bonded. The following software programs and computer were used: structure solution, SHELXS-97 [17]; refinement, SHELXL-97 [18]; molecular diagrams, ORTEP-3 [19]; computer, Intel CoreDuo.

\textbf{Plant Material.} Rhizomes of \textit{Metaxya rostrata} C.Presl. were collected in February 2003 in the surroundings of La Gamba, south-western Costa Rica, and authenticated in the Herbarium of the Museo National in San Jose by Dr. Werner Haber. Voucher specimens (Voucher number: MR0203) are deposited with the Herbarium of the Department of Pharmacognosy, University of Vienna, Austria.
Extraction and Isolation. Dried roots (800 g) of Metaxya rostrata C. Presl were pulverized and portions of 100 g each were extracted by sonification at 50 °C with 1 l H$_2$O, each. The extraction was repeated five times with the same amount of solvent. After lyophilization, the residue (80 g) was extracted sequentially with AcOEt, BuOH, and MeOH. The fractions of different polarity (AcOEt fraction (0.75 g), BuOH fraction (26.35 g), and MeOH fraction (18.7 g)) were subjected to vacuum liquid chromatography (VLC) on silica (15 – 40 μm, Merck) with AcOEt/MeOH/H$_2$O mixtures of increasing polarity as mobile phases. All obtained fractions after these three fractionation steps were pooled according to their composition to 15 combined fractions [1].

Fr. 12 was chosen for further separation in this study and subjected to column chromatography (CC) on Sephadex LH-20 (3 x 65 cm) with 80% MeOH. Of 13 subfractions, Frs. 12/3 (0.50 g), 12/4 (0.69 g), and 12/5 (0.55 g) were further fractionated.

Fr. 12/3 was subjected to CC (silica gel 60; particle size 0.063 – 0.200 mm; Merck; H$_2$O-sat. AcOEt/MeOH 90:10) to yield 13 subfractions. From Subfr. 12/3/3, compound 1 (58 mg) crystallized. Subfr. 12/3/10 was further purified by CC (Sephadex LH-20; 1 x 40 cm; 50% MeOH) to give 3 mg of compound 2 and Subfr. 12/3/2 by CC (silica gel 60; H$_2$O-sat. AcOEt) to afford 7 mg of compound 5.

Fr. 12/5 was subjected to CC (silica gel 60; H$_2$O-sat. AcOEt/MeOH 90:10) to yield nine subfractions. Subfr. 12/5/9 was further purified by CC (silica gel 60; H$_2$O-sat. AcOEt/MeOH 80:20) and resulted in the isolation of compound 3 (12 mg).

Fr. 12/4 was subjected to CC (silica gel 60; H$_2$O-sat. AcOEt/MeOH 90:10) to give compound 4 (1.2 mg).

Sugar Analysis. The determination of the absolute configuration of the sugar was achieved after enzymatic hydrolysis of 1 mg of compound 1 with β-glucuronidase (No. G0751 from Helix pomatia;
Sigma-Aldrich, A-Vienna), butylation with \((-\)-(R)-butan-2-ol, and derivatization with N-methyl-N-(trimethylsilyl)trifluoroacetamide according to [5][6]. GC/MS Analyses were performed on a GCMS-QP 2010 (Shimadzu Corporation, Kyoto, Japan) according to [6].

\((\text{R,2E})-2-(6\text{-Hydroxyxilidene})\text{cyclopropyl} \beta\text{-d-Glucopyranoside} (1)\). Colorless needles. M.p.: 129 – 131°. \([\delta]_D^2 = -74.9 (c = 0.41, \text{MeOH})\). \textbf{Cytotoxicity Assay.} SW-480 Carcinoma cells obtained from the American Type Culture Collection and cultivated under standard conditions (minimal essential medium (MEM) containing 10% fetal calf serum (FCS)) were used to assess the cytotoxic capacity of compounds 1 and 2. Cell viability was assessed by neutral red uptake assay [14].

Financial support of the FWF (project-No. P20354) is gratefully acknowledged. We thank Alexander Roller (University of Vienna, Institute of Inorganic Chemistry) for single-crystal X-ray diffraction measurements.
