SELECTIVITY ON DIVISION ALGEBRAS

LUIS ARENAS-CARMONA

Abstract. A commutative order in a central simple algebra over a number field is said to be selective if it embeds in some, but not all, maximal orders in the algebra. We completely characterize selective orders in central division algebras, of dimension 9 or greater, in terms of the characterization of selective orders given by Chindburg and Friedman in the quaternionic case.

1. Introduction

Back in 1936, Chevalley [7] proved that the number \( q \) of conjugacy classes of maximal orders, in a matrix algebra \( B \), over a number field \( K \), containing a copy of the ring of integers of a fixed maximal subfield \( L \) of \( B \) had the form

\[
q = N/[H \cap L : K],
\]

where \( N \) is the total number of conjugacy classes and \( H \) is the Hilbert class field of \( K \). An analog result was later proved in 1999 by Chinburg and Friedman [8] for a quaternion algebra \( Q \) satisfying the Eichler condition, where they gave necessary and sufficient conditions for a commutative suborder to be contained in every maximal order in \( Q \). When this fails to be the case, the order is called selective and embeds into exactly one half of all conjugacy classes. This result was later extended to Eichler orders by several authors [9], [6]. We ourselves proved in [2] that Chevalley’s formula \( q = N/[H \cap L : K] \) remains valid for central simple algebras without partial ramification, i.e., for algebras that are either division algebras, or pure matrix algebras, at every finite place, as long as the Hilbert class field is replaced by another class field, which we called the spinor class field \( \Sigma \). Furthermore in 2012, in a second paper [3], we proved we always have the identity \( q = N/[F : K] \), for some explicit subfield \( F \subseteq L \cap \Sigma \) defined by certain splitting conditions, although the equality \( F = L \cap \Sigma \) does not hold in general. The field \( F \) is called the representation field.

In all of this work, a commutative order is called selective for a central simple algebra \( B \) if it embeds in some, but not all, the conjugacy classes of maximal orders in \( B \). In the notations of the previous paragraph,
an order $\mathfrak{H}$ is selective if and only if the representation field $F = F(\mathfrak{H})$ strictly contains $K$. The same year that $[3]$ was published, Linowitz and Shemanske $[11]$ noted that selectivity was not possible in a division algebra $B$ when $\sqrt{\dim_K(B)}$ is an odd prime. Furthermore, in a recent pre-print $[12]$, the same authors proved that selectivity is not possible in an algebra $B$ that had a fully ramified place. The condition implies, in particular, that $B$ is a division algebra. This hinted us that the situation for division algebras could be simpler than for more general central simple algebras. While it is easy to find commutative orders of rank $n$, in a $n^2$ dimensional matrix algebra, whose the selectivity rate $q$ is $1/n$, provided that $n$ divides the annihilator of the abelian group $\text{Gal}(H/K)$, the corresponding rate in division algebras can be only 0, 1, or $1/2$. In fact, we show in Theorem 1 below that the selectivity that was found by Chindburg and Friedman in quaternion algebras is, in a sense, responsible for all selectivity on division algebras.

**Theorem 1.1.** Let $K$ be a number field. Let $B$ be a division $K$-algebra, and let $L \subseteq B$ be a maximal subfield. Let $\mathfrak{H}$ be an arbitrary order in $L$. If $\mathfrak{H}$ is selective in $B$, the following conditions hold:

1. $\sqrt{\dim_K(B)}$ is twice an odd number,
2. the ramification degree of $B$ at every finite place is odd,
3. $B$ has a decomposition $B = B_1 \otimes_K B_2$, where $B_1$ is a quaternion algebra and $B_2$ is an odd dimensional division algebra.
4. $L$ contains a quadratic extension that is selective for $B_1$.

On the other hand, if $L$ and $B$ satisfy these conditions, then $\mathcal{O}_L$ embeds into exactly one half of all isomorphism classes of maximal orders in $B$.

Is it worth to note that, aside from the last statement, the proof of this result uses only the trivial bound $F \subseteq L \cap \Sigma$, and not the precise computation of $F$ in $[3]$. The main idea behind the proof, which also seems to be present in the previous work by Linowitz and Shemanske, is that a field that intersects "too much" the spinor class field $\Sigma$ must forfeit the necessary conditions to be embedded in the algebra $B$.

The arithmetic of maximal orders in quaternion division algebras is central in the construction of isospectral non-isometrical varieties in $[14]$ and $[13]$. Lack of selectivity is particularly important in this construction see for example $[10] \S 5.1$.

2. **The Brauer Group of a Number Field**

In this section we recall the structure results for the Brauer group of a number field that are needed to prove our main result. The proof
of these results can be found in [1]. Recall that every central simple algebra over a field $K$ is isomorphic to a ring of matrices $M_n(D)$ with entries in a central division $K$-algebra $D$. The Brauer group $\text{Br}(K)$ of $K$ is a group whose element are equivalence classes of central simple algebras over $K$, where two algebras $M_n(D)$ and $M_m(B)$ are in the same class if and only if the division algebras $D$ and $B$ are isomorphic. In this group, the identity is the class of the $K$-algebra $K$, and the inverse of a class $[C]$ is the class $[C^\text{op}]$ corresponding to the algebra $C^\text{op}$ which is isomorphic to $C$ as a vector space, but endowed with the opposite multiplication $a \ast b = b \cdot a$. The group operation is $[C][D] = [C \otimes_K D]$.

For any field $F$ containing $K$, there is a homomorphism $\phi : \text{Br}(K) \to \text{Br}(F)$ sending the class of a $K$-algebra $C$ to the class of the central simple $F$-algebra $C \otimes_K F$. In these terms, for any number field $K$ there exists an exact sequence

$$0 \to \text{Br}(K) \to \prod_{\mathfrak{p} \in \Pi(K)} \text{Br}(K_{\mathfrak{p}}) \to \mathbb{Q}/\mathbb{Z} \to 0,$$

where $\Pi(K)$ is the set of all places of $K$, including the archimedean places. In particular, a central simple $K$-algebra $A$ is completely determined by the set of completions $A_{\mathfrak{p}}$. The brauer group of the completion $K_{\mathfrak{p}}$ is given by

$$\text{Br}(K_{\mathfrak{p}}) \cong \begin{cases} \mathbb{Z}/2\mathbb{Z} & \text{if } K_{\mathfrak{p}} \cong \mathbb{R} \\ \{0\} & \text{if } K_{\mathfrak{p}} \cong \mathbb{C} \\ \mathbb{Q}/\mathbb{Z} & \text{otherwise} \end{cases}.$$

Identifying $\mathbb{Z}/2\mathbb{Z}$ with $(\frac{1}{2}\mathbb{Z})/\mathbb{Z}$, one can associate to a central simple algebra $A$, the Hasse invariant $i_\mathfrak{p}(A) \in \mathbb{Q}/\mathbb{Z}$, for every local place $\mathfrak{p}$, with the obvious restrictions at the archimedean places, and satisfying the properties

$$i_\mathfrak{p}(A) = 0 \text{ for almost all } \mathfrak{p}, \quad \sum_{\mathfrak{p} \in \Pi(K)} i_\mathfrak{p}(A) = 0.$$

Furthermore, for any positive integer $n$, the elements of order $n$ in the Brauer group are exactly the classes of $n^2$-dimensional central division $K$-algebras. It follows that every element in $\text{Br}(K)$ annihilated by $n$ is the class of a $n^2$-dimensional central simple $K$-algebra. The order of any class $[C]$ in the brauer group $\text{Br}(K)$ is the least common multiple of the orders (i.e., denominators) of the invariants $i_\mathfrak{p}(C)$. This local order is, by definition, the ramification degree $e_\mathfrak{p}(B/K)$. In particular, if $C$ is an $n^2$-dimensional division algebra, and $p$ is a prime dividing $n$, there must exists a local place $\mathfrak{p}$ such that $p^{i_\mathfrak{p}(n)}$ divides $e_\mathfrak{p}(B/K)$,
where \( v_p(n) \) is the \( p \)-adic valuation of \( n \), i.e., the largest integer \( v \) such that \( p^v \) divides \( n \). This observation is used in all that follows.

### 3. The theory of representation fields

Let \( K \) be a number field and let \( \mathfrak{A} \) be a central simple \( K \)-algebra. Two orders of maximal rank \( \mathfrak{D} \) and \( \mathfrak{D}' \) are said to be in the same genus if the completions \( \mathfrak{D}_\varphi \) and \( \mathfrak{D}'_\varphi \) are conjugate for every finite place \( \varphi \in \Pi(K) \). For simplicity, we write \( \mathfrak{D}_\varphi = \mathfrak{A}_\varphi \) whenever \( \varphi \in \Pi(K) \) is archimedean. If we define the adelizations \( \mathfrak{A}_H \) and \( \mathfrak{D}_H \) of the algebra \( \mathfrak{A} \) and the order \( \mathfrak{D} \) by the formulas

\[
\mathfrak{A}_H = \left\{ a \in \prod_{\varphi \in \Pi(K)} \mathfrak{A}_\varphi \middle| a_\varphi \in \mathfrak{D}_\varphi \text{ for almost every } \varphi \in \Pi(K) \right\},
\]

two orders \( \mathfrak{D} \) and \( \mathfrak{D}' \) are in the same genus if and only if \( \mathfrak{D}'_H = a\mathfrak{D}_H a^{-1} \) for some element \( a \in \mathfrak{A}_H \). They are in the same spinor genus when \( a \) can be chosen in the form \( a = bc \) where every coordinate \( b_\varphi \) of \( b \) has reduced norm 1, while \( c \in \mathfrak{A} \) is a global element. It is known that two orders in the same spinor genus are conjugate whenever the Eichler Condition holds, i.e., \( \mathfrak{A} \) is not the algebra of Hamilton’s Quaternions for at least one infinite place \( \varphi \). This is certainly the case when the dimension of \( \mathfrak{A} \) is not 4, or when \( K \) is not totally real. On the other hand, the set of spinor genera in a genus \( \text{gen}(\mathfrak{D}) \) is in correspondence with the Galois group over \( K \) of the spinor class field \( \Sigma = \Sigma(\mathfrak{D}) \), i.e., the class field corresponding to the class group \( K^*H(\mathfrak{D}) \) where

\[
H(\mathfrak{D}) = \{ N(a)\mid a \in \mathfrak{A}_H^*, a\mathfrak{D}_H a^{-1} = \mathfrak{D}_H \} \subseteq J_K.
\]

The spinor genus containing a second order \( \mathfrak{D}' \) corresponds to the element \( \rho(\mathfrak{D}, \mathfrak{D}') \in \text{Gal}(\Sigma/K) \) defined by \( \rho(\mathfrak{D}, \mathfrak{D}') = [N(a), \Sigma/K] \) where \( \mathfrak{D}'_H = a\mathfrak{D}_H a^{-1} \), and \( x \mapsto [x, \Sigma/K] \) is the Artin map on ideles. In particular, the number of spinor genera containing some supra-order \( \mathfrak{D}' \in \text{gen}(\mathfrak{D}) \) of a fixed order \( \mathfrak{H} \subseteq \mathfrak{A} \) is \( [\Sigma : F] \), where \( F \) is the class field corresponding to the class group \( K^*H(\mathfrak{D} \mid \mathfrak{H}) \), where

\[
H(\mathfrak{D} \mid \mathfrak{H}) = \{ N(a)\mid a \in \mathfrak{A}_H^*, a\mathfrak{H} a^{-1} \subseteq \mathfrak{D} \},
\]

provided that \( K^*H(\mathfrak{D} \mid \mathfrak{H}) \) is actually a group. This is not always the case, but it holds when \( \mathfrak{H} \) is commutative and \( \mathfrak{D} \) is maximal \(^3\). It is immediate from the definition of \( H(\mathfrak{D} \mid \mathfrak{H}) \), that we have the contention \( F \subseteq L \cap \Sigma \) for any maximal field \( L \) containing \( \mathfrak{H} \). This is the only bound needed in the sequel. A stronger bound of the form \( F \subseteq F_0(\mathfrak{A} \mid \mathfrak{H}) \cap \)

\(^3\) It is well known that the definition of \( \mathfrak{A}_H \) given here is independent of the choice of \( \mathfrak{D} \), see for example \(^3\).
Σ, was used in [4] to prove that an order contained in a quadratic extension is spinor selective for some genus in exactly one quaternion algebra. The field $F_0(\mathfrak{A}|\mathfrak{H})$ is the class field corresponding to a class group $K^*H(\mathfrak{H})$ whose definition is analogous to (1).

There is a unique genus of maximal orders in an $n^2$-dimensional central simple algebra $\mathfrak{A}$. Furthermore, the spinor class field $\Sigma_0$ for the genus of maximal orders is characterized as the largest unramified exponent-$n$ extension of the ground field $K$ satisfying the following conditions [2, §2]:

- $\Sigma_0/K$ is unramified at every infinite place $\wp$ where $\mathfrak{A}_\wp$ is a matrix algebra.
- At every finite place $\wp$, the inertia degree $f_\wp(\Sigma_0/K)$ divides $f = f_\wp(\mathfrak{A}/K)$, where $\mathfrak{A}_\wp \cong M_f(\mathfrak{B})$ for a local division algebra $\mathfrak{B}$.

4. Proof of the main result

Let $B$ be an $n^2$-dimensional central division $K$-algebra, and let $p$ be a prime dividing $n$. In particular, $B$ has order $n$ in the Brauer group of $K$ (§2). Furthermore, for every fixed prime $p$, there exists a finite place $\wp$ such that the ramification degree $e_\wp(B/K)$ is divisible by $p^t$, where $t = v_p(n)$ is the $p$-adic valuation of $n$. By the description of the spinor class field given in §3, the inertia degree $f_\wp(\Sigma_0/K)$ must be relatively prime to $p$, and the same holds for $f_\wp(F/K)$, where $F$ is the representation field. Recall also that the ramification degree $e_\wp(F/K)$ is 1 since $\Sigma/K$ is unramified at finite places.

Now let $\mathfrak{P}$ be a place of $L$ lying over $\wp$. The condition that $L$ embeds into $B$ implies that $e_\wp(B/K)$ divides the local degree $[L_\mathfrak{P} : K_\wp]$. In particular, $p^t$ divides $[L_\mathfrak{P} : K_\wp]$. Since the extension $F/K$ is abelian, we conclude that $p^t$ divides $[L_\mathfrak{P} : F_{\wp'}]$ where $\wp'$ is the restriction of $\mathfrak{P}$ to $F$. Since this holds for every place $\mathfrak{P}$ of $L$ lying over $\wp$, we conclude that $p^t$ divides

$$[L : F] = \sum_{\mathfrak{P}|\wp'} [L_\mathfrak{P} : F_{\wp'}].$$

In particular, $p$ does not divide $[F : K]$.

A similar argument holds for $p = 2$ when $v_2(n) \geq 2$. This proves (1). On the other hand, if $v_2(n) = 1$ and the ramification degree $e(B_\wp/K_\wp)$ is even, for a finite place $\wp$, the same argument proves that 2 does not divide $[F : K]$ and therefore again $[F : K] = 1$, so (2) follows.

We assume (1) and (2) in all that follows. In particular, $B$ has odd ramification degree at every finite prime, while the set $T$, of real places where $B$ has ramification degree 2, is non-empty. The order of
the set $T$ must be even, since $\sum_\wp i_\wp(B) \in \mathbb{Q}/\mathbb{Z}$, and therefore also its projection on the $2$-torsion of $\mathbb{Q}/\mathbb{Z}$, must vanish. There exists, therefore, a quaternion algebra $B_1$ ramifying at exactly the places in $T$. Similarly, there exists an odd dimensional CSA $B_2$ ramifying at the same finite places as $B$ and with the same Hasse invariants, satisfying $\dim_K(B_2) = n/2^v(n)$. Note that $B_2$ is a division algebra since, for every fixed odd prime $p$ dividing $n$, there exists a finite place $\wp$ such that the ramification degree $e_\wp(B_1/K)$ is divisible by $p^v(n)$. Furthermore, both $B$ and $B_1 \otimes_K B_2$ have the same invariants. We conclude (3).

Recall that the proportion of spinor genera representing $\mathfrak{H}$ in the genus $\mathcal{O}_0$ of maximal orders, is $[F : K]^{-1}$. The first part of the argument showed that $[F : K] = 2$, since we are assuming the order is selective and every prime-power divisor larger than 2 has been ruled out as a divisor of $[F : K]$. In particular $F$ is a quadratic extension of $K$. We claim that it satisfies the conditions in (4).

First we prove that $F \subseteq L$ embeds into $B_1$. Note that the reduced norm of every element in $B$ is positive at all places in $T$, since $B$ is a matrix algebra over the Hamilton quaternions at those places. Since $L$ embeds into $B$, so does the subfield $F$, and in fact, if $\alpha \in F$, then $N_{L/K}(\alpha) = N_{F/K}(\alpha)[L:F] > 0$ implies $N_{F/K}(\alpha) > 0$, since $[L:F]$ is odd. We conclude that $F/K$ ramifies at every place in $T$, whence $F$ satisfies the sufficient conditions of the Albert-Brauer-Hasse-Noether Theorem [10, Theorem 6.1.1] to embeds into $B_1$.

Now we assume that $L$ satisfies conditions (1)-(4), and let $E/K$ be the quadratic extension in (4). It was proved in [5] that $E$, and therefore also $L$, is selective. Here we give an independent proof for the sake of completeness. Identify $L$ with a subalgebra of $B$. Let $\mathfrak{H} = \mathcal{O}_L$, and let $\mathfrak{D}$ be a maximal order in $B$ containing $\mathfrak{H}$. It suffices to prove that the representation field $F(\mathfrak{D}/\mathfrak{H})$ contains $E$. For this, it suffices to prove that the relative spinor image $H(\mathfrak{D}/\mathfrak{H})$ is contained in $H_E = K^* N_{E/K}(J_E)$.

Note that, by hypothesis, $\mathcal{O}_E$ is selective in $B_1$, and $N_{B_1}(B_1^*) = N_B(B^*)$ at every archimedean place, since $B_2$ is a matrix algebra at those places. On the other hand, $N_{B_1}(B_1^*)$ is contained in $H_E$ at all places, since $\mathcal{O}_E$ is selective for $B_1$. It suffices therefore to prove the contention at finite places. Note that $E/K$ is unramified. Let $\wp$ be a finite place inert for $E/K$, and let $\mathfrak{P}$ be the unique place of $E$ lying over $\wp$. We need to prove that $H_\wp(\mathfrak{D}/\mathfrak{H})$ is contained in $\mathcal{O}_E^* K_\wp^{*2}$. By [3, Theorem 1], it suffices to prove that every irreducible representation of the residual algebra $\mathbb{H}_\wp$ has even dimension. Here, $\mathbb{H}_\wp$ is the image of $\mathfrak{H}$ in the quotient $\mathfrak{D}/\wp$, where $I$ is the unique maximal two-sided ideal
Note that $H_\wp$ is a quotient of $\mathcal{H}_\wp/\pi\mathcal{H}_\wp$ where $\pi$ is a uniformizing parameter of $K_\wp$. Since $\mathcal{H}$ is an algebra over the ring of integers $\mathcal{O}_E$, and therefore $\mathcal{H}_\wp$ is an algebra over the ring of integers $\mathcal{O}_{E_\wp}$ of the unique unramified quadratic extension $E_\wp$ of $K_\wp$, we conclude that $H_\wp$ is an algebra over the residue field of $E_\wp$, and the result follows. □
