Background. Banxia Baizhu Tianma Decoction (BBTD) is a traditional Chinese medicine (TCM) and has been revealed to promote symptoms of preeclampsia (PE) in clinical practice. However, its mechanisms of action and molecular targets for the treatment of PE are not clear. Method. The potential mechanisms of the BBTD against PE were explored using network pharmacology approach and bioinformatic analysis. The PE animal model was induced by phosphatidylserine/dioleoyl-phosphatidylcholine. The effects of BBTD in the treatment of PE were evaluated in vitro and in vivo. The expressions of RNA and proteins were measured by quantitative real-time polymerase chain reaction and western blotting, respectively. The cell behavior was detected using the MTT assay, Transwell assay, and flow cytometry assay. Results. A total of 173 active compounds of BBTD with 346 targets were identified, and 516 target genes related to PE were also identified from databases. 195 candidate targets for BBTD were screened from the merged PPI network of BBTD-target proteins and PE-related targets. The pathway enrichment analyses showed that the BBTD had the potential to influence a variety of biological pathways. Further pathway-gene network analysis suggested BBTD may improve symptoms of PE via several genes, including MDM2, TP53, RELA, MYC, AKT1, and EGFR. The validation results demonstrated that BBTD treatment promoted pregnancy outcome in the PE animal model. Meanwhile, BBTD regulated the gene expression of MDM2, TP53, RELA, MYC, and EGFR and inhibited the EGFR-JAK/STAT signaling pathway in placental tissue and trophoblast cells. In addition, BBTD promoted the proliferation and invasion and reduced the apoptosis of trophoblast cells. Conclusion. BBTD improved PE by inhibiting the EGFR-JAK/STAT signaling pathway and promoting the proliferation and invasion and reduced the apoptosis of trophoblast cells.

1. Introduction

Preeclampsia (PE) is a serious pregnancy-related disorder and one of the main causes of maternal and fetal morbidity and mortality worldwide [1]. It is characterized by proteinuria, hypertension, unexplained seizure, and severe headache [2]. Insulin resistance, increased systemic inflammatory response, and endothelial dysfunction are also present in PE [3]. The diagnosis of PE can be made in the absence of proteinuria, if there is laboratory evidence of target organ damage as demonstrated by either thrombocytopenia, renal insufficiency, impaired liver function tests, or pulmonary oedema [4]. PE is a multifactorial disorder that results from changes in complex pathophysiological processes due to several genetic and environmental factors. Diabetes-induced vascular damage, renal disease, pre-existing hypertension, nulliparity, elevated maternal body mass index, and older age are some of the known risk factors of PE. Although our understanding of the pathophysiology of PE has grown enormously over the past few decades, the options for intervention remain limited. Therefore, it is necessary to develop novel therapeutic...
methods for PE, particularly in those developing countries with the greatest burden of disease [5].

Traditional Chinese Medicine (TCM), an important part of complementary and alternative medicine, is widely accepted and used in clinical practice. Banxia Bai Zhu Tianma Decoction (BBTD) is made up of 13 kinds of herbs: Banxia 10 g (Arum bernatnum), Tianma 15 g (Rhizoma Gastrodiae), Baishu 15 g (Atractylodes macrocephala), Fuling 20 g (Poria cocos), Jupi 12 g (Citrus reticulata), Cangshu 15 g (Atractylodes lancea), Gouteng 15 g (Uncariae Ramulus Cum Uncis), Huangqi 9 g (Hedysarum multimajum), Danshen 15 g (Radix Salviae), Renshen 9 g (Panax ginseng), Shichangpu 15 g (Acoritatinowii Rhizoma), Yujin 15 g (Curcumae Radix), and Huangbai 6 g (Phellodendri Chinensis Cortex). It has been reported that the BBTD was effective for many diseases, including vertebrobasilar insufficiency vertigo [6], hyperlipidemia [7], sympathetic nervous cervical spondylosis [8], and hypertension [9]. Recently, the therapeutic function of the BBTD for PE has also been revealed, and it suggested that the BBTD improved the clinical symptoms and related examination indexes of early-onset severe pre-eclampsia, as well as reducing the incidence of fetal distress and growth restriction [10]. The function and certain mechanism of Gouteng against PE were recently explored; it was suggested that the anti-inflammation effect of Gouteng might be an alternative therapy for PE [11]. However, the comprehensive molecular mechanisms of the BBTD against PE remain unclear.

Network pharmacology with systematic and holistic characteristics has become a promising method to explain the complex interactions between herbs and diseases at the system level. It combines oral bioavailability prediction, multiple drug target prediction, and network analysis to understand the active compounds and therapeutic targets of TCM [12]. It has developed rapidly and been widely used in the TCM studies [13, 14]. This study provided a systematic method for mapping the mechanism of action of BBTD in the treatment of PE and identifying potential protein targets that coordinate synergistic effects of TCM. In vitro and in vivo experiments were conducted to validate the effects of BBTD on PE and the underlying mechanisms. We undertook this study to provide insight into the further in-depth development of the basic experimental research and clinical rational application of BBTD.

2. Materials and Methods

2.1. Compounds Screening and Targets Identification. To collect the herbal compounds of BBTD, we utilized the Traditional Chinese Medicine Systems Pharmacology Database (TCMSP, http://lsp.nwu.edu.cn/) and the Chinese Academy of Sciences chemistry database (CASC, http://www.organchem.csdb.cn/scdb/main/) to screen active compounds of BBTD. The candidate compounds which have oral bioavailability (OB) ≥ 30% and drug-likeness (DL) ≥ 0.18 were identified as active compounds. A bioactive molecule with high OB displays good DL, which is a qualitative concept utilized in drug design to optimize pharmaceutical and pharmacokinetic properties of molecules, such as chemical stability and solubility. The targets of candidate compounds were obtained from the TCMSP database. The network of compounds-targets was constructed using Cytoscape 3.7.1 software.

2.2. Disease-Related Targets. Details on the human genes associated with PE were acquired from three databases: (1) Comparative Toxicogenomics Database (CTD, https://www.pharmgkb.org/), (2) OMIM (https://www.omim.org/), and (3) GeneCards (https://www.genecards.org/). The gene identifiers were also converted into official gene symbols using an R-script linking the website of PubMed (https://www.ncbi.nlm.nih.gov/gene/), and only human genes were included for further analysis.

2.3. Screening of Common Targets and Networks Construction. Common target genes for drugs and diseases were obtained, and a network of the compound-common targets was constructed. The PPI networks of the compound targets and PE targets were constructed and visualized using Cytoscape 3.7.1 software using the plugin Bisogenet of Cytoscape 3.7.1 software [15], which obtains PPI data from the following six databases: Database of Interacting Proteins, Biological General Repository for Interaction Datasets, Human Protein Reference Database, IntAct Molecular Interaction Database, Molecular Interaction Database, and Biomolecular Interaction Network Database.

2.4. Bioinformatic Analysis. GO and KEGG enrichment analysis was carried out using the Database for Annotation, Visualization, and Integrated Discovery (DAVID, https://david.ncifcrf.gov, v6.8). Functional categories were enriched within genes (P < 0.05) and the top 10 GO functional categories were illustrated. Pathways that had significant changes of P < 0.05 were identified for further analysis. The genes that significantly regulated pathways were selected for gene-pathway network analysis and key target genes were identified from the gene-pathway network.

2.5. BBTD Preparation. Herbs that consisted of Banxia 10 g, Tianma 15 g, Baishu 15 g, Fuling 20 g, Jupi 12 g, Cangshu 15 g, Gouteng 15 g, Huangqi 9 g, Danshen 15 g, Renshen 9 g, Shichangpu 15 g, Yujin 15 g, and Huangbai 6 g were decocted for 60 min, and the decoction filtrate was concentrated to 200 mL (0.28 g/mL) to obtain the BBTD decoction.

2.6. Animal Studies. ICR mice were obtained from Kay Biological Technology Co., Ltd. (Shanghai, China). The study was approved by the Research Ethics Committee of Ningbo Women and Children’s Hospital. Preeclampsia in mice was induced by tail vein injection of 1 mg phosphatidylserine/dioleoyl-phosphatidylcholine (PS/PC) (Sigma-Aldrich, St. Louis, MO, USA) suspension from days 5 to 17 of pregnancy as previously described [16]. Saline was used as control. All pregnant female mice were divided into control.
group \((n = 8)\) and PE group \((n = 32)\). PE mice were orally given BBTD at 3.96, 7.92, and 15.84 g/kg/day for 16 days, while sham operation group and the control group were given olive oil for 16 days.

Proteinuria was detected using urine protein test kit (Jiancheng Institute of Biotechnology, Nanjing, China) on day 16. The systolic blood pressure (SBP) of each mouse was measured on gestation day 0 (GD0), GD4, GD8, GD12, and GD16 using the tail-cuff method (BP-2000; Visitech Systems, Apex, NC, USA). Then, the mice were anesthetized and sacrificed with 10% chloral hydrate (3 ml/kg, intraperitoneal injection). Placentas and fetuses were harvested from the mice and weighed. The collected placentas were used for subsequent experiments.

2.7. Cell Culture and Treatment. The chorionic trophoblast tissue was isolated from the placentas in the control group and PE group, cut into slices with a thickness of about 3 mm, and digested with 0.25% pancreatin in a 37°C water bath 3 times, each for 10 minutes. Cell suspension was obtained by centrifuging at 3000 rpm for 5 min to remove precipitation, washed twice with PBS, and then resuspended in DMEM/F12 containing 10% FBS, and inoculated in a culture plate at 37°C and 5% CO\(_2\) in an incubator. After being identified as impurity-free trophoblast cells, they were further cultured in a 37°C, 5% CO\(_2\) incubator. Trophoblast cells from PE mice model pretreated with or without 10 μg/mL BBTD for 30 min and trophoblast cells from the control group were used for further experiments.

2.8. MTT Assay. Cell viability was detected using an MTT assay kit (Sigma-Aldrich, St. Louis, MO, USA) according to the manufacturer’s protocol. Briefly, trophoblast cells \((1 \times 10^6)\) were seeded into 96-well plates. After culturing for 24, 48, 72 h, and 96 h, 10 μL of 5 mg/mL MTT solution (Shanghai Biyuntian Bio-Technology Co., Ltd., Shanghai, China) was added to each well and then incubated in a 37°C, 5% CO\(_2\) incubator for 4 h. The absorbance at 570 nm was measured with a microplate reader (MG Lab’Tech, Durham, NC, USA).

2.9. Flow Cytometry Assay. The effects of BBTD on cell apoptosis were measured using Annexin V-FITC/PI staining kit (Roche, Swiss) according to the manufacturer’s instruction. Briefly, the cells were seeded into a 6-well plate for 24 h. Then, the cells were collected and washed with PBS. After centrifugation at 1500 rpm for 3 min, the cell pellet was resuspended in 100 μL Annexin V-FITC/PI labeling solution and incubated for 10–15 min. Then, the apoptotic cells were analyzed immediately on a flow cytometer (Beckman Coulter, USA).

2.10. Transwell Assay. Cells were adjusted to 1 × 10^5 cells/mL and 150 μL of cell suspension was added into the Transwell chamber (Merck Millipore, Burlington, MA, USA) with a porous membrane pre-coated with or without migration Matrigel solution (Sigma-Aldrich, St. Louis, MO, USA). Complete medium \((500 \text{ ml})\) was added to the lower chamber. Cells were incubated for 48 h. Cells that had traversed the lower compartment were fixed with methanol, stained with 0.1% crystal violet (Sigma-Aldrich, St. Louis, MO, USA) and counted by light microscopy.

2.11. Quantitative Reverse Transcription PCR (qRT-PCR). The total RNA was extracted from the cells and placentas tissue using TRIzol (Invitrogen, Carlsbad, CA, USA). cDNA was reverse-transcribed from RNA by iScript advanced cDNA Synthesis Kit (BioRad, Hercules, CA, USA). RT-PCR was performed with SYBR Green chemistry (Thermo Fisher Scientific, MA, USA) on a 7500 fast RT-PCR system. The glyceraldehyde-3-phosphate \((\text{GAPDH})\) mRNA level was used as control in this experiment. All sequences of primers used in RT-PCR are shown in Table 1.

2.12. Western Blot. Total protein was extracted from the cells and placentas tissue by radioimmunoprecipitation assay buffer (Beyotime Biotechnology, Shanghai, China) and stored at −20°C. Proteins in each sample were separated by 10% SDS-PAGE, following gel transfer onto PVDF membranes and blocking in PBS containing 5% non-fat milk for 2 h at room temperature. Then, we added primary anti-bodies JAK (cat. No. ab133666, 1:1200, Abcam), p-JAK (cat. No. ab138005, 1:1200, Abcam), STAT3 (cat. No. ab68153, 1:1000, Abcam), p-STAT3 (cat. No. ab267373, 1:1000, Abcam), EGFR (cat. No. ab52894, 1:1000, Abcam), and GAPDH (cat. No. ab8245, 1:1000, Abcam) for 12 h at 4°C. The protein was washed with membrane-washing buffer 3 times (5 minutes per time), followed by the addition of secondary antibodies and incubation at room temperature for 1 h. The membrane was visualized using ECL system (Pierce, Rockford, USA), and Image J software was used for band intensity quantification.

2.13. Statistical Analysis. SPSS version 17.0 was used to perform the statistical analysis. All data were presented as mean ± standard deviation (SD). The differences among the groups were evaluated by one-way ANOVA. \(P < 0.05\) was considered to be statistically significant.

3. Results

3.1. Screening of Active Compounds of BBTD and Their Targets. In total, 245 compounds in BBTD were searched from the TCMSP database. Of these, 9 were from Atractyloides Lancea, 7 were from Atractyloides macrocephala, 4 were from Acoritatinowii Rhizoma, 13 were from Arum ternatum, 15 were from Curcumae Radix, 5 were from Citrus reticulata, 20 were from Hedysarum multijugum, 15 were from Poria cocos, 37 were from Phellodendri Chinensis Cortex, 22 were from Panax ginseng, 65 were from Radix Salviae, and 33 were from Uncariae Ramulus Cum Uncis. Owing to the lack of information about compounds of Rhizoma Gastrodiae in the TCMSP, 13 representative

3.2. Construction of the Compounds-Targets Network. To further understand the complex interactions between the compounds and their corresponding targets at a system level, we constructed a compound-target network based on the candidate compounds of BBTD and their targets (Figure 1). The network contained 519 nodes (173 compounds in BBTD and 346 targets) and 2729 edges which indicated the compound-target interactions. All candidate compounds had a median of 12 degrees, suggesting that most compounds of BBTD affected multiple targets. Based on the degree value, the top six compounds were quercetin, luteolin, kaempferol, naringenin, and tanshinone, the degrees of which were 73, 31, 28, 23, 19, and 17, respectively.

3.3. Disease Targets. PE-related targets were identified from GeneCard (218), CTD (310), and OMIM (60) databases. After compensating for data redundancy, 516 target genes were finally included (Table S2). Of these, 106 were targets of the herbs comprising BBTD, which verifies its therapeutic potential as an anti-PE TCM formulation. We constructed and analyzed the compound anti-PE targets network (Figure 2). Based on degree centrality, the top six active compounds in BBTD were quercetin, luteolin, kaempferol, wogonin, naringenin, and tanshinone, the degrees of which were 73, 31, 28, 23, 19, and 17, respectively.

3.4. Identification of Candidate BBTD Targets Responsible for Treatment of PE. PPI involves various biological processes and is regarded as the primary objective of system biology [17]. In order to reveal the mechanisms of action underlying effects of BBTD on PE, the PPI network of BBTD putative targets and the PPI network of PE-related targets were merged to identify the candidate targets for BBTD against PE. First, a putative target PPI network of BBTD-related genes was constructed with 8687 nodes and 191788 edges on a systems pharmacology platform. After further extraction of PE-related targets, a disease-specific network was constructed with 9401 nodes and 201905 edges. We then merged these two networks to obtain a core PPI network with 7695 nodes and 177332 edges. Subsequently, candidate PE-related proteins modified by BBTD were screened based on the topological features of the core PPI. A node is identified as a significant target if its degree was more than twice the median degree of all nodes in the network [18]; the median degree in our network was 25. Thus, we constructed a network of significant targets of BBTD with 2039 nodes and 84681 edges. Using a Cytoscape plugin (CytoNCA), we selected the following seven topological features to identify candidate targets: betweenness centrality (BC), degree centrality (DC), closeness centrality (CC), eigenvector centrality (EC), network centrality (NC), and local average connectivity (LAC) [19]. The median values of BC, CC, DC, EC, LAC, and NC were 788.4383, 0.4799, 86, 0.0120, 10.6032, and 11.6740, respectively. Thus, we identified 195 candidate targets with values for these topological features higher than the median values of CC and two times of other five median values. A representative flowchart of the screening process is presented in Figure 3.

3.5. GO and KEGG Enrichment Analysis. Four hundred ninety-two GO terms, with 316 in biological process, 79 in cellular component, and 97 in molecular function, were significantly enriched (P-value < 0.05). The top 10 terms are shown in Figure 4. The highly enriched GO terms in molecular function, cellular component, and biological process included poly(A) binding, protein binding, nucleoplasm, membrane, nucleus, extracellular exosome, telomere organization, nucleosome assembly, and regulation of gene expression. Sixty-two significantly enriched pathways (P-value < 0.005) including thyroid hormone signaling pathway, estrogen signaling pathway, PI3K-Akt signaling pathway, MAPK signaling pathway, neurotrophin signaling pathway were identified. Top 20 enriched pathways are shown in Figure 5; the size of the spot represented the number of genes and color represented –log FDR value.

3.6. Gene-Pathway Network Analysis. To further investigate the core genes involved in the anti-PE effect of BBTD, the significantly enriched pathways (with P-value < 0.001) and the related genes were obtained to construct the gene-pathway network, as shown in Figure 6. The topological analysis of the 28 pathways and 136 genes was carried out with BC, and the results suggested that RPS6 had the most...
maximum BC and was the core target gene. Other several genes also had larger BC, such as MDM2, MAPK1, TP53, NFKB1, RELA, MYC, and DDX5. Among these, MDM2, TP53, RELA, MYC, AKT1, and EGFR were direct targets of BBTD with higher BC, suggesting that they might be the key target genes for BBTD against PE.

3.7. The Effects of BBTD on PE Animal Mice. To study the effect of BBTD on the pregnancy outcome of PE model mice, we compared the systolic blood pressure, proteinuria, and fetal weight of mice in each group. The results showed that BBTD treatment significantly ameliorated SBP and proteinuria levels and increased fetal weights in preeclampsia animal model in a dose-dependent manner (Table 2). Meanwhile, BBTD treatment reduced the elevated gene expression of p53 and EGFR and increased the down-regulated gene expression of MDM2, RELA, and MYC in PE animal model (Figure 7(a)). In addition, the upregulated protein expression of EGFR and the elevated ratio of p-JAK/JAK and p-STAT/STAT in PE mice model were also decreased by BBTD treatment in a dose-dependent manner (Figure 7(b)–7(d)), suggesting that the beneficial effects of BBTD on PE might be associated with the regulation of these core genes and the inhibition of EGFR-JAK/STAT signaling pathway.

3.8. The Effects of BBTD on Trophoblast Cells. We found that the cell proliferation of trophoblast cells was significantly decreased in PE mice model, while BBTD treatment partially reversed this effect (Figure 8(a)). Further, we detected the
4. Discussion

In China, the unique theory of TCM has been formed and developed over two thousand years for treating and preventing various diseases, including cardiovascular disease [20], neurological diseases [21], and cancer [22]. The most prominent feature of TCM is the multi-component, multi-target, multi-pathway comprehensive treatment of diseases to achieve the effect of improving symptoms and curing.
diseases with fewer side effects. Various active ingredients in complex TCM formulations improve therapeutic effect through synergism [23]. PE is a multifactorial disorder and manifests as a maternal phenotype including hypertension and proteinuria with or without other multiorgan dysfunctions, or as the fetal phenotype including intrauterine growth retardation [24], which is suitable for treatment using TCM theory. The application of TCM or integrated TCM and western medicine on the treatment of PE has attracted widespread attention and research by clinicians. BBTD consists of 13 herbs and is mainly used in the treatment of vertigo [6] and hypertension [25], and recently a study also confirmed its function to improve symptoms of PE [10]. Our data demonstrated that BBTD improved pregnancy outcomes in PE mice models, including ameliorating SBP and proteinuria levels, as well as increasing fetal weights. Furthermore, the underlying mechanisms of BBTD actions on PE were explored using network pharmacology and validated via in vivo and in vitro experiments.

In the network pharmacology analysis, a compound-compound targets network of BBTD with 519 nods and 2729 edges was constructed. The results indicated that many compounds with a higher degree, such as quercetin, kaempferol, luteolin, 7-O-methylisomucronulatol, wogonin, and succinic acid, may be the pleiotropically crucial active compounds for BBTD. Quercetin is a polyphenol derived from plants and has been shown to exert multiple pharmacological activities, including anti-carcinogenic [26], anti-inflammatory [27], and antiviral activities [28]. It has also been reported that quercetin could be used for the prevention and/or treatment of preeclampsia owing to its protection against the placental secreted messengers released under preeclampsia-like stress conditions like placental hypoxia [29]. Normal pregnancy evokes a systemic inflammatory response and the response is exacerbated in preeclampsia and can account for its clinical features [30]. Kaempferol and wogonins are representative flavonoids with anti-oxidant, anti-inflammatory, anti-cancer, anti-diabetic, anti-osteoarthritic, and immunomodulatory properties [31–33]. Luteolin also showed anti-cancer [34], anti-oxidant, anti-inflammatory, and anti-allergic properties [35]. It sug-
gested that kaempferol, luteolin, and wogonins may improve symptoms of PE through their anti-inflammatory and immunomodulatory properties.

To further explore the potential targets of BBTD against PE, we constructed and merged the PPI network of compound-targets and PE-related targets for candidate targets for BBTD against PE. 195 targets were finally identified and used to carry out the enrichment analysis to elucidate the mechanisms underlying the anti-PE effects of BBTD. GO analysis suggested that BBTD regulated some biological processes, such as epigenetic regulation of gene expression, telomere organization, and gene silence. Recent studies demonstrated the importance of maternal epigenetic features, including DNA methylation [36], histone modifications [37], epigenetically regulated miRNA [38], and the effect of imprinted genes on trophoblast growth and invasion in pregnancy [39], which may be potential mechanisms that underlie the theories of disease for PE. Telomeres are essential components of linear chromosomes to protect against chromosome end-fusions and genomic instability and are involved in the whole reproductive system. Previous evidence showed that telomeres are shorter in placentas from preeclampsia and telomere aggregate formation in preeclampsia was increased [40]. Therefore, BBTD may exert a regulatory function in the pathogenesis of PE by regulating telomeres organization. In addition, it may also affect some cellular components and molecular function including nucleoplasm, nucleus, cytosol, protein binding, enzyme binding, and DNA binding in the treatment of PE.

BBTD is a complex TCM formulation with multiple target pathways, which were enriched in KEGG analysis. In the present study, a total of 62 KEGG pathways including thyroid hormone signaling pathway, PI3K-Akt signaling pathway, estrogen signaling pathway, and MAPK signaling pathway were significantly enriched. Thyroid hormones regulate neurodevelopment, probably from early fetal life onwards, and may lead to preterm birth in preeclampsia, and its level is associated with the severity and outcome of preeclampsia [41]. MAPKs participate in the regulation of gene expression, immune response, cell proliferation, apoptosis, and response to oxidative stress, which is one of the mechanisms of immune regulation [42], and the crosstalk between MAPK and PI3K-AKT signaling pathways contributes to the balance of the innate immune responses [43]. Estrogen is produced primarily in the placenta during pregnancy, and its abnormalities could play a crucial role in PE because they are exclusively produced by the placenta and promote angiogenesis and vasodilation [44]. Therefore, BBTD may improve symptoms of PE through the related pathways. In addition, several pathways related to virus were also significantly enriched, such as viral carcinogenesis, hepatitis B, and Epstein–Barr virus infection. It has been reported that viral infection was associated with a twofold
higher risk of preeclampsia [45]. Therefore, the autoimmune response triggered by viral infection might be regulated by BBTD via viral-related pathways. It has also been revealed that dysregulation of canonical cancer molecular pathways occurred in preeclampsia [46], and our results also suggested that BBTD may treat PE via some cancer-related pathways, such as transcriptional misregulation in cancer, pathways in cancer, and prostate cancer pathway. In vitro and in vivo experiments demonstrated that BBTD inhibited the activated EGFR-JAK/STAT signaling pathway in placental tissue and trophoblast cells of PE mice model. EGFR was involved in the PI3K-Akt signaling pathway and MAPK signaling pathway, and the JAK/STAT signaling pathway was associated with the pathogenesis of PE [47, 48].

Gene-pathway network was constructed to investigate the core and key target genes for BBTD against PE. The

results suggested that RPS6 had the maximum BC and it might be the core target and other genes with higher BC, such as MDM2, MAPK1, TP53, NFKB1, RELA, MYC, and DDX5, were identified as key target genes. Moreover, MDM2, TP53, RELA, MYC, AKT1, and EGFR were direct targets with higher BC of BBTD against PE. In vivo and in vitro experiments confirmed the regulation of p53, MDM2, RELA, MYC, and EGFR gene expression by BBTD. Evidence has confirmed the association between PE and alterations in the p53-pathway, and imbalance in p53 and MDM2 expression promotes excessive apoptosis in villous trophoblast [49]. In addition, it also suggested that p53 may conceivably serve as a potential therapeutic target to improve the placental-related disease and pregnancy outcomes. AKT acts on a variety of targets involved in many cellular processes, such as metabolism, cell cycle, survival, and differentiation [50–52]. It has been demonstrated that placental pathology in preeclampsia and retarded fetuses is related to changes in the expression pattern of EGFR [53], and the antiangiogenic factor, sFlt-1 (soluble FMS-like tyrosine kinase-1), has been strongly implicated in the pathogenesis of preeclampsia and was mediated by EGFR signaling [54].

**Figure 7:** BBTD treatment influenced the gene expression and EGFR-JAK/STAT signaling pathway. (a) The effects of BBTD on the gene expression of P53, MDM2, RELA, MYC, AKT1, and EGFR. (b) Western blot of the EGFR, p-JAK, JAK, p-STAT, and STAT. (c) The statistical analysis of the WB results of EGFR. (d) The statistical analysis of the WB results of p-JAK/JAK and p-STAT/STAT.
Figure 8: The effects of BBTD on the trophoblast cells. (a) BBTD treatment promoted the proliferation of trophoblast cells, (b) BBTD treatment upregulated the expression of the indicators of cell proliferation (PCNA and Ki67), (c) BBTD promoted the invasive cell number of trophoblast cells, (d) the statistical analysis of the invasive cell number, (e) BBTD reduced the elevated apoptosis rate of trophoblast cells in PE, (f) the statistical analysis of the apoptosis data, (g) qPCR results in each group, (h) western blot results in each group, (i) the statistical analysis of the p-JAK/JAK and p-STAT/STAT, and (j) the statistical analysis of the EGFR protein expression.
5. Conclusion

In the present study, we applied a network pharmacology approach to predict, elucidate, and confirm the potential mechanisms of the BBTD on PE. It was demonstrated that BBTD promoted pregnancy outcome in PE animal model and the proliferation and invasion and reduced the apoptosis of trophoblast cells. In addition, BBTD functions on the regulation of P53 MDM2, RELA, MYC, and EGFR gene expression and the inhibition of EGFR-JAK/STAT signaling pathway. In this study, we provided the preliminary information and basis for further exploration of BBTD’s mechanisms of action on PE, as well as a reference for studying the complex mechanism of action of TCM.

Abbreviations

BBTD: Banxia Baizhu Tianma Decoction
TCM: Traditional Chinese medicine
PE: Preeclampsia
PPI: Protein-protein interaction
OB: Oral bioavailability
DL: Drug-likeness
BC: Betweenness centrality
DC: Degree centrality
CC: Closeness centrality
EC: Eigenvector centrality
NC: Network centrality
LAC: Local average connectivity

Data Availability

The datasets used and/or analyzed during the current study are available from the corresponding author upon reasonable request.

Conflicts of Interest

The authors declare that they have no conflicts of interest.

Authors’ Contributions

SQC and XJL conceived and designed the study. SQC collected the data. AEC HBL performed animal experiments. SQC, LLY, and XJL conducted the data analysis. SQC and XJL wrote the manuscript. All authors were equally responsible for reviewing the data. All authors read and approved the final manuscript.

Acknowledgments

This article was supported by the Medical and Health Project of Zhejiang Province (Grant no. 2020KY890) and the Social Development Public Welfare Foundation of Ningbo (Grant nos. 202002N3150 and 2019C50070).

Supplementary Materials

Table S1: the characteristics of active compounds in BBTD.
Table S2: the PE-related targets obtained from different databases. (Supplementary Materials)
