Conclusion. Granger causality tests are commonly used in economic modeling but have not been routinely applied to infectious diseases. Using this test, we found a strong correlation between weekly cases of hospitalized influenza and iGAS septic shock or pneumonia. This approach can provide insight into the potential impact of developing prevention interventions for infections with strong correlation. Further exploration of Granger tests in infectious disease modeling should be considered.

686. Use of an Influenza-Like Illness School Absenteeism Monitoring System to Identify Seasonal Influenza Outbreaks in the Community: ORCHARDS (Wisconsin, September 2014–June 2017)
Jonathan Temte, MD, PhD; Yentil Zhethayeva, MD, MPH; Shari Barlow, BA; Middlesex-Gates, Madeline; Temte, BA; Amber Schoendorf, MS; Cristalyne Bell, BA; Erik Reisdorf, MPH; Peter Shult, PhD; Mary Wedig, BS; Thomas Haupt, MS; James Conway, MD FAAFP; Ronald Gangnon, PhD; Ashley Fowlkes, MPH and Amra Uzicanin, MD, MPH; Family Medicine, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin, 2Department of Biostatistics and Medical Informatics, School of Medicine and Public Health, University of Wisconsin - Madison, Madison, Wisconsin, 3Influenza Division, Centers for Disease Control and Prevention, Atlanta, Georgia, 4Communicable Disease Division, Wisconsin State Laboratory of Hygiene, Madison, Wisconsin, 5Bureau of Communicable Diseases, Wisconsin Division of Public Health, Madison, Wisconsin, 6Pediatrics, University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin, 7Department of Biostatistics and Medical Informatics, School of Medicine and Public Health, University of Wisconsin - Madison, Madison, Wisconsin, 8Influenza Division, Centers for Disease Control and Prevention, Atlanta, Georgia, 9CDC, Atlanta, Georgia

Session: 66. Public Health: Epidemiology and Outbreaks
Thursday, October 4, 2018: 12:30 PM

Background. School absenteeism monitoring as a means for early detection of influenza activity is a suggested approach to identify seasonal influenza outbreaks within the Oregon School District, Oregon, WI (OSD: enrollment = 3,900 students). The study definition of a-ILI was validated for 700 children with acute respiratory illness (ARI) at the clinic. The study definition of a-ILI was significantly correlated with MAI in the community respectively. Influenza was significantly associated with a-ILI status (OR = 4.74; 95% CI: 2.78–8.18; P < 0.001). Of MAI patients, 371 had influenza A and 143 had influenza B. a-ILI was significantly correlated with MAI in the community (r = 0.480; P < 0.001) with a 15-day lead time. a-ILI was significantly correlated with MAI in the community (r = 0.480; P < 0.001) with a 1-day lead time. a-ILI performed poorly (r = 0.278; P > 0.001), following MAI by 9 days (Figure 1).

Conclusion. Surveillance using case-specific absenteeism was feasible to implement in OSD and performed well over a 3-year period marked by diverse presentations of seasonal influenza. Monitoring a 1- and a-ILI can detect influenza outbreaks in the community, providing early warning in time for community mitigation efforts for seasonal and pandemic influenza.

Session: 66. Public Health: Epidemiology and Outbreaks
Thursday, October 4, 2018: 12:30 PM

Background. Influenza illness can range from mild to severe, with serious outcomes occurring in children and the elderly. Flu has been studied extensively in geographies where vaccine is often plentiful. The burden of influenza is not well known in tropical regions where vaccine coverage is scant. Our study examines the impact of introducing flu vaccination in Cameroon. We developed ordinary differential equations (ODEs) under the SEIR compartmental model and calculated R0. We estimated the proportion of cases the clinics observed to make inferences to the catchment population of these health facilities. We developed another set of ODEs to introduce vaccination using a pulse function with a 50% efficacy and 45% vaccination coverage.

Conclusion. We observed vaccination at 45% coverage (US average). Cameroon would likely achieve reduced coverage. Therefore, we examined introducing vaccination with 10% coverage, and observed that flu cases were cut by over one third.

Session: 66. Public Health: Epidemiology and Outbreaks
Thursday, October 4, 2018: 12:30 PM

Background. A severe 2017–2018 influenza season was expected for the United States. We hypothesized that a surge in influenza cases paired with decreased vaccine effectiveness could increase healthcare worker (HCW) absenteeism. Because of a potential public health emergency during the 2017–2018 season, we offered oseltamivir post-exposure prophylaxis (PEP) to exposed HCWs regardless of vaccination status. We describe PEP uptake, cost, and impact on absenteeism at the University of Iowa Hospital and Clinics (UIHC).

Methods. UIHC serves as a referral and safety net health system for Eastern Iowa. Influenza seasons were defined as the period between Week 40 from 1 year to Week 13 of the following year. During the 2016–2017 season, PEP (75 mg/day for 7 days) was offered free of charge to unvaccinated exposed HCWs. Exposure was defined as proximity within 3 ft of a confirmed influenza-infected person for 10 minutes without mask protection, or direct contact with respiratory secretions. During the 2017–2018 season, PEP was expanded to all exposed HCWs regardless of vaccination status. We reviewed surveillance, employee health, pharmacy, and human resources records for the 2016–2017 and 2017–2018 seasons. We defined PEP uptake as prescriptions picked up/all referrals and absenteeism rate as sick-leave requests/scheduled hours.

Results. During the 2016–2017 and 2017–2018 seasons, we detected 373 and 427 confirmed influenza cases among patients at UIHC. HCW vaccination rates were similar: 89.7% and 90.9%. PEP was recommended in 49 exposures during 2016–2017 and 280 exposures during 2017–2018. A total of 22 (44.9%) and 133 (47.5%) HCWs picked up oseltamivir from the pharmacy during the 2016–2017 and 2017–2018 seasons. The estimated cost of oseltamivir was $1,791 and $10,828, respectively. Overall, 1,187 sick-leave requests (median = 12 hours, absenteeism rate = 3.2%), and 6,174 sick-leave requests (median = 12 hours, absenteeism rate = 3.4%) were reported during the 2016–2017 and 2017–2018 seasons.

Conclusion. Influenza case counts mildly increased from the 2016–2017 to the 2017–2018 season. Expanding PEP to all exposed HCWs, regardless of vaccination status, had moderate uptake and was costly. Absenteeism rates remained similar during both seasons.
