Variational inequalities theory, which was introduced in the sixties, has emerged as an interesting and fascinating branch of applicable mathematics with a wide range of applications in industry, finance, economics, social, and pure and applied sciences. This field is dynamic and is experiencing an explosive growth in both theory and applications; as a consequence, research techniques and problems are drawn from various fields. The ideas and techniques of variational inequalities are being applied in a variety of diverse areas of sciences and prove to be productive and innovative. It has been shown that this theory provides the most natural, direct, simple, unified, and efficient framework for a general treatment of a wide class of unrelated linear and nonlinear problems. Variational inequalities have been extended and generalized in several directions using novel and new techniques. In parallel, optimization methods based on proximal point and proximal-like type methods have attracted a large number of researchers in the last three decades. In the same spirit, we can cite, for instance, the alternating direction multipliers method, which is based on the augmented lagrangian algorithm, which itself can be seen as a direct application of the proximal point algorithm to the dual problem of a constrained optimization problem.

The aim of this special issue is to present new approaches and theories for variational inequalities arising in mathematics and applied sciences. This special issue includes 14 high-quality peer-reviewed papers that deal with different aspects of variational inequalities. These papers contain some new, novel, and innovative techniques and ideas. We hope that all the papers published in this special issue can motivate and foster further scientific works and development of the research in the area of theory, algorithms, and applications of variational inequalities.

The summaries of the 14 papers in this issue are listed as follows.

The paper of C. Chen et al. considers a class of linearly constrained separable convex programming problems without coupled variables. They weaken some conditions to obtain convergence of the alternating direction method of multipliers and they propose also a relaxed ADMM involving an additional computation of optimal step size and establish its global convergence under mild conditions.

The paper of H. Sun and Y. Wang revisits the global error bound for the generalized nonlinear complementarity problem over a polyhedral cone (GNCP) and sharpens the global error bound for the GNCP under weaker conditions, which improves the existing error bound estimation for the problem.

The paper of M. Ma concerns the design and the convergence analysis of algorithms to split variational inequality and equilibrium problems.

The paper of Y. Wang and C. Wang gives a new modified Ishikawa type iteration algorithm for common fixed points of total asymptotically strict pseudocontractive semigroups.
Strong and weak convergence are proved under mild conditions. Furthermore, the main results presented in this work extend and improve some recent results.

The paper of X. Fu presents an implementable proximal step by a slight relaxation to the subproblem of proximal point algorithm (PPA) to solve linearly constrained convex programming. Self-adaptive strategies are proposed to improve the convergence in practice. The paper also discusses some applications and performs some numerical experiments to confirm the efficiency of the proposed method.

The paper of H. Xu establishes the strong convergence of prediction-correction and relaxed hybrid steepest-descent method (PRH method) for variational inequalities under some suitable conditions that simplify the proof. Further, the author shows the efficiency of the proposed algorithm through a well-designed set of practical numerical experiments.

The paper of M. Xu et al. considers the study of some matrix optimization problems using the proximal alternating direction method. The authors show that the restriction on the proximal parameters can be relaxed for solving these kinds of problems and give some numerical experiments to conclude that their modified method presents better performance than the classical proximal alternating direction method.

The paper of J.-L. Jiang et al. considers the locations of multiple facilities in the space \( \mathbb{R}^p \), with the aim of minimizing the sum of weighted distances between facilities and regional customers, where the proximity between a facility and a regional customer is evaluated by the closest distance. And the authors propose a new location-allocation heuristic scheme to solve their problem. Convergence is proved under mild assumptions; and furthermore some preliminary numerical results are reported to show the effectiveness of the new algorithm.

The paper of A. Roldan et al. studies the existence and uniqueness of coincidence point for nonlinear mappings of any number of arguments under a weak \((\varphi, \psi)\)-contractivity condition in partial metric spaces. The obtained results generalize, extend, and unify several classical and very recent related results in the literature in metric spaces and in partial metric spaces.

The paper of Z. Jia et al. extends the convergence analysis given by Han and Yuan for alternating direction method of multipliers (ADMM) from the strongly convex to a more general case. Further, the authors prove under the assumption that the individual functions are composites of strongly convex functions and linear functions that the classical ADMM for separable convex programming with two blocks can be extended to the case with more than three blocks.

The paper of M. Li and Y. You presents a simple proof for the same convergence rate of the relaxed proximal point algorithm (PPA) in both ergodic and nonergodic senses.

The paper of W.-S. Du et al. extends, generalizes, and improves several fundamental results on the existence (and uniqueness) of coincidence points and fixed points for well-known maps in the literature. Furthermore, some fixed coincidence point theorems for multivalued nonself maps in the context of complete metric spaces are given.

The paper of F. Ma et al. develops, studies, and implements a new prediction-correction method for monotone variational inequalities with separable structure. At each iteration, the proposed algorithm also allows the involved subvariational inequalities to be solved in parallel.

The paper of A. Barbagallo and P. Mauro concerns a dynamic oligopolistic market equilibrium problem in the realistic case in which the presence of capacity constraints and production excesses are allowed and, moreover, the production function depends not only on the time but also on the equilibrium distribution. The authors prove the equivalence between this equilibrium definition and a suitable evolutionary quasi-variational inequality, and they study the analysis of existence, regularity, and sensitivity of solutions.

**Acknowledgments**

We would like to express our sincere thanks to the authors for contributing to this issue, as well as to the anonymous reviewers for their generous and accurate refereeing process and their valuable comments and suggestions. Without their evident support this special issue would not have come out. We want to also acknowledge with gratitude the assistance and help provided by the editorial board members of this journal during the preparation of this special issue.

Abstract and Applied Analysis
Volume 2014, Article ID 598563, 10 pages
http://dx.doi.org/10.1155/2014/598563

1. Introduction

This paper concerns the following problem:

\[ \min_X \left\{ \frac{1}{2} \|X - C\|_F^2 \mid X \in S_n^+ \cap S_B \right\}, \tag{1} \]

where \( C \in R^{n \times n} \) is a given symmetric matrix,

\[ S_n^+ = \{ X \in R^{n \times n} \mid X^T = X, X \succeq 0 \}, \]

\[ S_B = \{ X \in R^{n \times n} \mid \text{Tr}(A_i X) = b_i, i = 1, 2, \ldots, p, \text{Tr}(G_j X) \leq d_j, j = 1, 2, \ldots, m \}, \tag{2} \]

matrices \( A_i \in R^{n \times n} \) and \( G_j \in R^{n \times n} \) are symmetric and scalars, \( b_i \) and \( d_j \) are the problem data, \( X \succeq 0 \) denotes that \( X \) is a positive semidefinite matrix, \( \text{Tr} \) denotes the trace of a matrix, and \( \| \cdot \|_F \) denotes the Frobenius norm; that is,

\[ \|X\|_F = \left( \text{Tr} \left( X^T X \right) \right)^{1/2} = \left( \sum_{i,j=1}^{n} X_{ij}^2 \right)^{1/2}, \tag{3} \]

and \( S_n^+ \cap S_B \) is nonempty. Throughout this paper, we assume that the Slater’s constraint qualification condition holds so that there is no duality gap if we use Lagrangian techniques to find the optimal solution to problem (1).

Problem (1) is a type of matrix nearness problem, that is, the problem of finding a matrix that satisfies some properties and is nearest to a given one. Problem (1) can be called the least squares covariance adjustment problem or the least squares semidefinite programming problem and solved by many methods [1–4]. In a least squares covariance adjustment problem, we make adjustments to a symmetric matrix so that it is consistent with prior knowledge or assumptions and a valid covariance matrix [2, 5, 6]. The matrix nearness problem has many applications especially in several areas of numerical linear algebra, finance industry, and statistics in [6]. A recent survey of matrix nearness problems can be found in [7]. It is clear that the matrix nearness problem considered here is a convex optimization problem. It thus follows from the strict feasibility and coercivity of the objective function that the minimum of (1) is attainable and unique.
In the literature of interior point algorithms, \( S^n_p \) is called the semidefinite cone and the related problem (1) belongs to the class of semidefinite programming (SDP) and second-order cone programming (SOCP) \([8]\). In fact, it is possible to reformulate problem (1) into a mixed SDP and SOCP as in \([3, 9]\):

\[
\begin{align*}
\min & \quad t \\
\text{s.t.} & \quad \langle A_i, X \rangle = b_i, \quad i = 1, 2, \ldots, p, \\
& \quad \langle G_j, X \rangle \leq d_j, \quad j = 1, 2, \ldots, m, \\
& \quad t \geq \|X - C\|_F, \\
& \quad X \in S^n_p,
\end{align*}
\]

where \( \langle X, Y \rangle = \text{Tr}(X^TY) \).

Thus, problem (1) can be efficiently solved by standard interior-point methods such as SeDuMi \([10]\) and SDPT3 \([11]\) when the number of variables (i.e., entries in the matrix \( X \)) is modest, say under 1000 (corresponds to \( n \) around 32) and the number of equality and inequality constraints is not too large (say 5,000) \([2, 3, 12]\).

Specially, let

\[
S_B = \{ X \in R^n_{+} | \text{Diag} (X) = e \},
\]

where \( \text{Diag}(X) \) is the vector of diagonal elements of \( X \) and \( e \) is the vector of 1s. Then problem (1) can be viewed as the nearest correlation matrix problem. For the nearest correlation matrix problem, a quadratically convergent Newton algorithm was presented recently by Qi and Sun \([13]\), and improved by Borsdorf and Higham \([1]\). For problem (1) with equality and inequality constraints, one difficulty in finding an efficient method for solving this problem is the presence of the inequality constraints. In \([3]\), Gao and Sun overcome this difficulty by reformulating the problem as a system of semismooth equations with two level metric projection operators and then design an inexact smoothing Newton method to solve the resulting semismooth system. For the problem (1) with large number of equality and inequality constraints, the numerical experiments in \([14]\) show that the alternating direction method (hereafter alternating direction method is abbreviated as ADM) is more efficient in computing time than the inexact smoothing Newton method which additionally requires solving a large system of linear equations at each iteration. The ADM has many applications in solving optimization problems \([15, 16]\). Papers written by Zhang, Han, Li, Yuan, and Bauschke and Borwein show that the ADM can be applied to solve convex feasibility problems \([17–19]\).

The proximal ADM is a class of ADM type methods which can also be easily applied to solve the matrix optimization problems. Generally, the proximal parameters (i.e., the parameters \( r \) and \( s \) in \([14] \) and \([15]\)) of the proximal ADM are greater than zero. In this paper, we will show that the restriction on the proximal parameters can be relaxed while the proximal ADM is used to solve problem (1). Numerical experiments also show that the proximal ADM with the relaxed proximal parameters generally has a better performance than the classical proximal ADM.

The paper is organized as follows. In Section 2, we give some preliminaries about the proximal alternating direction method. In Section 3, we convert the problem (1) to a structured variational inequality and apply the proximal ADM to solve it. The basic analysis and convergent results of the proximal ADM with relaxed proximal parameters are built in Section 4. Preliminary numerical results are reported in Section 5. Finally, we give some conclusions in Section 6.

## 2. Proximal Alternating Direction Method

In order to introduce the proximal ADM, we first consider the following structured variational inequality problem which includes two separable subvariational inequality problems: find \( (x, y) \in \Omega \) such that

\[
\begin{align*}
\left(x' - x\right)^T f (x) & \geq 0, \\
\left(y' - y\right)^T g (y) & \geq 0,
\end{align*}
\]

\( \forall (x', y') \in \Omega \),

where

\[
\Omega = \{ (x, y) \mid Ax + By = b, x \in \mathcal{X}, y \in \mathcal{Y} \},
\]

\( f : R^m_+ \rightarrow R^m_+ \) and \( g : R^r_+ \rightarrow R^r_+ \) are monotone; that is,

\[
\begin{align*}
\left(\bar{x} - x\right)^T (f (\bar{x}) - f (x)) & \geq 0, \quad \forall \bar{x}, x \in R^m_+,
\end{align*}
\]

\( \left(\bar{y} - y\right)^T (g (\bar{y}) - g (y)) \geq 0, \quad \forall \bar{y}, y \in R^r_+ \),

\( A \in R^{\ell \times \ell}, B \in R^{\ell \times s}, \) and \( b \in R^\ell; \mathcal{X} \subset R^m_+ \) and \( \mathcal{Y} \subset R^r_+ \) are closed convex sets. Studies of such variational inequality can be found in Glowinski \([20]\), Glowinski and Le Tallec \([21]\), Eckstein and Fukushima \([22–24]\), He and Yang \([25]\), He et al. \([26]\), and Xu \([27]\).

By attaching a Lagrange multiplier vector \( \lambda \in R^d \) to the linear constraint \( Ax + By = b \), problem (6)-(7) can be explained as the following form (see \([20, 21, 24]\)): find \( \omega = (x, y, \lambda) \in \mathcal{W} \) such that

\[
\begin{align*}
\left(x' - x\right)^T \left[ f (x) - A^T \lambda \right] & \geq 0, \\
\left(y' - y\right)^T \left[ g (y) - B^T \lambda \right] & \geq 0, \\
& \quad \forall \omega' = (x', y', \lambda') \in \mathcal{W}, \\
& \quad Ax + By = b = 0,
\end{align*}
\]

where

\[
\mathcal{W} = \mathcal{X} \times \mathcal{Y} \times R^d.
\]

For solving (9)-(10), Gabay \([28]\) and Gabay and Mercier \([29]\) proposed the ADM method. In the classical ADM method, the new iterate \( \omega^{k+1} = (x^{k+1}, y^{k+1}, \lambda^{k+1}) \in \mathcal{W} \) is generated from a given triple \( \omega^k = (x^k, y^k, \lambda^k) \in \mathcal{W} \) via the following procedure.

First, \( x^{k+1} \) is found by solving the following problem:

\[
\begin{align*}
\left(x' - x\right)^T \left\{ f (x) - A^T \left[ \lambda^k - \beta (Ax + By^k - b) \right] \right\} & \geq 0,
\end{align*}
\]

\( \forall x' \in \mathcal{X} \).
where $x \in \mathcal{X}$. Then, $y^{k+1}$ is obtained by solving
\[
(y' - y)^T \left[ g(y) - B^T \left[ \lambda^k - \beta \left( Ax^{k+1} + By - b \right) \right] \right] \geq 0,
\forall y' \in \mathcal{Y},
\] (12)
where $y \in \mathcal{Y}$. Finally, the multiplier is updated by
\[
\lambda^{k+1} = \lambda - \beta \left( Ax^{k+1} + By^{k+1} - b \right),
\] (13)
where $\beta > 0$ is a given penalty parameter for the linearly constraint $Ax + By - b = 0$. Most of the existing ADM methods require that the subvariational inequality problems (II)-(12) should be solved exactly at each iteration. Note that the involved subvariational inequality problems (II)-(12) may not be well-conditioned without strongly monotone assumptions on $f$ and $g$. Hence, it is difficult to solve these subvariational inequality problems exactly in many cases. In order to improve the condition of solving the subproblem by the ADM, some proximal ADMs were proposed (see, e.g., [26, 27, 30–34]). The classical proximal ADM is one of the attractive ADMs. From a given triple $w^k = (x^k, y^k, \lambda^k) \in \mathcal{W}$, the classical proximal ADM produces the new iterate $w^{k+1} = (x^{k+1}, y^{k+1}, \lambda^{k+1}) \in \mathcal{W}$ by the following procedure.

First, $x^{k+1}$ is obtained by solving the following variational inequality problem:
\[
(x' - x)^T \left[ f(x) - A^T \left[ \lambda^k - \beta \left( Ax + By - b \right) \right] \right] + r \left( x - x^k \right) \geq 0, \quad \forall x' \in \mathcal{X},
\] (14)
where $r > 0$ is the given proximal parameter and $x \in \mathcal{X}$. Then, $y^{k+1}$ is found by solving
\[
(y' - y)^T \left[ g(y) - B^T \left[ \lambda^k - \beta \left( Ax^{k+1} + By - b \right) \right] \right] + s \left( y - y^k \right) \geq 0, \quad \forall y' \in \mathcal{Y},
\] (15)
where $s > 0$ is the given proximal parameter and $y \in \mathcal{Y}$. Finally, the multiplier is updated by
\[
\lambda^{k+1} = \lambda^k - \beta \left( Ax^{k+1} + By^{k+1} - b \right),
\] (16)

In this paper, we will conclude that problem (1) can be solved by the proximal ADM and the restriction on the proximal parameters $r > 0, s > 0$ can be relaxed as $r > -1/2, s > -1/2$ when the proximal ADM is applied to solve problem (1). Our numerical experiments later also show that the numerical performance of the proximal ADM with smaller value of proximal parameters is generally better than the proximal ADM with comparatively larger value of proximal parameters.

3. Converting Problem (1) to a Structured Variational Inequality

In order to solve the problem (1) with proximal ADM, we convert problem (1) to the following equivalent one:
\[
\begin{align*}
\min_{x,y} & \quad \frac{1}{2} \|X - C\|^2_F + \frac{1}{2} \|Y - C\|^2_F \\
\text{s.t.} & \quad X - Y = 0,
\end{align*}
\] (17)
\[
X \in S^+_n, \quad Y \in S_B.
\]
Following the KKT condition of (17), the solution to (17) can be found by finding $w = (X, Y, \Lambda) \in \mathcal{W}$ such that
\[
\begin{align*}
\left\langle X' - X, (X - C) - \Lambda \right\rangle & \geq 0, \\
\left\langle Y' - Y, (Y - C) + \Lambda \right\rangle & \geq 0, \quad \forall w' = (X', Y', \Lambda') \in \mathcal{W}, \\
X - Y & = 0,
\end{align*}
\] (18)
where
\[
\mathcal{W} = S^+_n \times S_B \times R^{m \times n}.
\] (19)

It is easy to see that problem (18)-(19) is a special case of the structured variational inequality (9)-(10) and thus can be solved by proximal ADM. For given $w^k = (X^k, Y^k, \Lambda^k) \in \mathcal{W}$, it is fortunate that the $w^{k+1} = (X^{k+1}, Y^{k+1}, \Lambda^{k+1})$ can be exactly obtained by the proximal ADM in the following way:
\[
X^{k+1} = P_{S^+_n} \left\{ \frac{1}{1 + \beta + r} \left( C + rX^k + \beta Y^k + \Lambda^k \right) \right\},
\] (20)
\[
Y^{k+1} = P_{S_B} \left\{ \frac{1}{1 + \beta + s} \left( C + \beta X^{k+1} + sY^k - \Lambda^k \right) \right\},
\] (21)
\[
\Lambda^{k+1} = \Lambda^k - \beta \left( X^{k+1} - Y^{k+1} \right),
\] (22)
where the projection of $v$ on a nonempty closed convex set $S$ of $R^{m \times n}$ under Frobenius norm, denoted by $P_S(v)$, is the unique solution to the following problem; that is,
\[
P_S(v) = \arg \min_u \left\{ \|u - v\|_F^2 \mid u \in S \right\}.
\] (23)

It follows that the solution to
\[
\min \left\{ \frac{1}{2} \|Z - X\|^2_F \mid Z \in S^+_n \right\}
\] (24)
is called the projection of $X$ on $S^+_n$ and denoted by $P_{S^+_n}(X)$. Using the fact that matrix Frobenius norm is invariant under unitary transform, it is known (see [35]) that
\[
P_{S^+_n}(X) = Q\tilde{\Lambda}Q^T,
\] (25)
where
\[
Q^TXQ = \text{diag} (\lambda_1, \ldots, \lambda_n)
\] (26)
is the symmetric Schur decomposition of $X (Q = (q_1, \ldots, q_n)$ is an orthogonal matrix whose column vector $q_i, i = 1, \ldots, n,$
is the eigenvector of $X$, and $\lambda_i$, $i = 1, \ldots, n$, is the related eigenvalue),
\[
\bar{\Lambda} = \text{diag} (\bar{\lambda}_1, \ldots, \bar{\lambda}_n), \quad \bar{\lambda}_i = \max (\lambda_i, 0).
\] (27)

In order to obtain the projection $P_{S_b} (X)$, we need to solve the following quadratic program:
\[
\min_{Z} \frac{1}{2} \| Z - X \|^2_F
\]
\[
\text{s.t.} \quad \text{Tr} (A_i Z) = b_i, \quad i = 1, 2, \ldots, p,
\]
\[
\text{Tr} (G_j Z) \leq d_j, \quad j = 1, 2, \ldots, m.
\] (28)

The dual problem of (28) can be written as
\[
\min_v \frac{1}{2} v^T H v + q^T v
\]
\[
s.t. \quad v \in \mathbb{R}^p \times \mathbb{R}^m,
\] (29)

where $H$ is positive semidefinite and $H$ and $q$ have the following form, respectively:
\[
H = \begin{pmatrix}
\text{Tr} (A_1 A_1^T) & \cdots & \text{Tr} (A_1 A_p^T) & \text{Tr} (A_1 G_1^T) & \cdots & \text{Tr} (A_1 G_m^T) \\
\vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
\text{Tr} (A_p A_p^T) & \cdots & \text{Tr} (A_p A_p^T) & \text{Tr} (A_p G_1^T) & \cdots & \text{Tr} (A_p G_m^T) \\
\text{Tr} (G_1 A_1^T) & \cdots & \text{Tr} (G_1 A_p^T) & \text{Tr} (G_1 G_1^T) & \cdots & \text{Tr} (G_1 G_m^T) \\
\vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
\text{Tr} (G_m A_1^T) & \cdots & \text{Tr} (G_m A_p^T) & \text{Tr} (G_m G_1^T) & \cdots & \text{Tr} (G_m G_m^T)
\end{pmatrix}
\]
\[
q = \begin{pmatrix}
b_1 - \text{Tr} (A_1 X) \\
\vdots \\
b_p - \text{Tr} (A_p X) \\
d_1 - \text{Tr} (G_1 X) \\
\vdots \\
d_m - \text{Tr} (G_m X)
\end{pmatrix}
\] (30)

Further, letting
\[
F (w^{k+1}) = \begin{pmatrix}
X^{k+1} - C - \Lambda^{k+1} \\
Y^{k+1} - C + \Lambda^{k+1} \\
X^{k+1} - Y^{k+1}
\end{pmatrix},
\]
\[
d_1 (w^k, w^{k+1}) = \begin{pmatrix}
r I_n & 0 & 0 \\
0 & (s + \beta) I_n & 0 \\
0 & 0 & \frac{1}{\beta} I_n
\end{pmatrix}
\begin{pmatrix}
X^k - X^{k+1} \\
Y^k - Y^{k+1} \\
X^k - Y^{k+1}
\end{pmatrix},
\] (34)

where $I_n \in \mathbb{R}^{n \times n}$ is the unit matrix, and
\[
d_2 (w^k, w^{k+1}) = F (w^{k+1}) - \beta \begin{pmatrix}
I_n & 0 \\
0 & -I_n
\end{pmatrix}
\begin{pmatrix}
Y^k - Y^{k+1}
\end{pmatrix},
\] (35)

then we can get the following lemmas.

\textbf{Lemma 1.} Let $\{w^k\}$ be the sequence generated by applying the proximal ADM to problem (18)-(19); then one has
\[
\langle w^{k+1} - w^*, d_2 (w^k, w^{k+1}) \rangle \\
\geq - \langle \Lambda^k - \Lambda^{k+1}, Y^k - Y^{k+1} \rangle + \| X^{k+1} - X^* \|^2_F \\
+ \| Y^{k+1} - Y^* \|^2_F.
\] (36)
Proof. From (22) and (35), we have
\[
\langle w^{k+1} - w^*, d_2 (w^k, w^{k+1}) \rangle = - \langle \Lambda^k - \Lambda^{k+1}, Y^k - Y^{k+1} \rangle \\
+ \langle w^{k+1} - w^*, F(w^{k+1}) \rangle.
\] (37)
Since (9) and \( w^* \) are a solution to problem (18)-(19) and \( X^{k+1} \in S^c, Y^{k+1} \in S_B \), we have
\[
\langle w^{k+1} - w^*, F(w^*) \rangle \geq 0.
\] (38)
From (38), it follows that
\[
\langle w^{k+1} - w^*, F(w^{k+1}) + F(w^*) \rangle \geq 0.
\] (39)
Thus, we have
\[
\langle w^{k+1} - w^*, F(w^{k+1}) \rangle \\
\geq \langle w^{k+1} - w^*, F(w^{k+1}) - F(w^*) \rangle \\
= \langle X^{k+1} - X^*, X^{k+1} - X^* - (\Lambda^{k+1} - \Lambda^*) \rangle \\
+ \langle Y^{k+1} - Y^*, Y^{k+1} - Y^* + (\Lambda^{k+1} - \Lambda^*) \rangle \\
+ \langle \Lambda^{k+1} - \Lambda^*, X^{k+1} - X^* - (Y^{k+1} - Y^*) \rangle \\
= \langle X^{k+1} - X^*, X^{k+1} - X^* \rangle \\
+ \langle Y^{k+1} - Y^*, Y^{k+1} - Y^* \rangle \\
= \|X^{k+1} - X^*\|^2_F + \|Y^{k+1} - Y^*\|^2_F.
\] (40)
Substituting (40) into (37), we get the assertion of this lemma. \( \square \)

Lemma 2. Let \( \{w^k\} \) be the sequence generated by applying the proximal ADM to problem (18)-(19) and let \( w^* \in \mathcal{W}^* \) be any solution to problem (18)-(19); then one has
\[
\langle w^k - w^*, G_0 (w^k - w^{k+1}) \rangle \\
\geq \langle w^k - w^{k+1}, G_0 (w^k - w^{k+1}) \rangle - \langle \Lambda^k - \Lambda^{k+1}, Y^k - Y^{k+1} \rangle \\
+ \|X^{k+1} - X^*\|^2_F + \|Y^{k+1} - Y^*\|^2_F,
\] (41)
where
\[
G_0 = \frac{1}{2} + r I_n \frac{1}{2} + s + \beta I_n \frac{1}{2} + \beta I_n
\] (42)
Proof. It follows from (33) that
\[
\langle w' - w^{k+1}, d_2 (w^k, w^{k+1}) - d_1 (w^k, w^{k+1}) \rangle \geq 0, \quad \forall w' \in \mathcal{W}.
\] (43)
Thus, we have
\[
\langle w^{k+1} - w^*, d_1 (w^k, w^{k+1}) \rangle \\
\geq \langle w^{k+1} - w^*, d_2 (w^k, w^{k+1}) \rangle \\
\geq - \langle \Lambda^k - \Lambda^{k+1}, Y^k - Y^{k+1} \rangle + \|X^{k+1} - X^*\|^2_F \\
+ \|Y^{k+1} - Y^*\|^2_F.
\] (44)
From the above inequality, we get
\[
\langle w^k - w^*, G_0 (w^k - w^{k+1}) \rangle \\
\geq \langle w^k - w^{k+1}, G_0 (w^k - w^{k+1}) \rangle - \langle \Lambda^k - \Lambda^{k+1}, Y^k - Y^{k+1} \rangle + \|X^{k+1} - X^*\|^2_F \\
+ \|Y^{k+1} - Y^*\|^2_F.
\] (45)
Hence, (41) holds and the proof is completed. \( \square \)

Theorem 3. Let \( \{w^k\} \) be the sequence generated by applying the proximal ADM to problem (18)-(19) and let \( w^* \in \mathcal{W}^* \) be any solution to problem (18)-(19); then one has
\[
\|w^{k+1} - w^*\|^2_G = \|w^k - w^*\|^2_G - \langle w^k - w^{k+1}, M (w^k - w^{k+1}) \rangle,
\] (46)
where
\[
M = \frac{1}{2} + r I_n \frac{1}{2} + s + \beta I_n \frac{1}{2} + \beta I_n
\] (47)
and \( \|w\|^2_G = \langle w, Gw \rangle \).
Proof. From (41), we have
\[
\|w^{k+1} - w^*\|^2_{G_0} \\
\leq \|w^k - w^* - (w^k - w^{k+1})\|^2_{G_0} \\
\leq \|w^k - w^*\|^2_{G_0} - 2 \|w^k - w^{k+1}\|^2_{G_0}
\]
\[ + 2 \langle \Lambda^k - \Lambda^{k+1}, Y^k - Y^{k+1} \rangle - 2\|X^{k+1} - X^*\|^2_F \\
- 2\|Y^{k+1} - Y^*\|^2_F + \|w^k - w^{k+1}\|^2_{G_0} \\
= \|w^k - w^*\|^2_{G_0} - \|w^k - w^{k+1}\|^2_{G_0} \]

\[ \|w^{k+1} - w^*\|^2_G \leq \|w^k - w^*\|^2_G \left( w^k - w^{k+1}, \begin{pmatrix} rI_n & 0 \\
0 & (s + \beta) I_n \end{pmatrix} \right) \left( \begin{array}{c} \frac{1}{\beta} I_n \\
0 
\end{array} \right) \left( w^k - w^{k+1} \right) - \left( \|X^{k+1} - X^*\|^2_F + \|X^k - X^*\|^2_F \right) \]

Using the Cauchy-Schwarz Inequality on the last term of the right-hand side of (49), we obtain
\[ \|X^{k+1} - X^*\|^2_F + \|X^k - X^*\|^2_F \geq \frac{1}{2}\|X^{k+1} - X^k\|^2_F, \]
\[ \|Y^{k+1} - Y^*\|^2_F + \|Y^k - Y^*\|^2_F \geq \frac{1}{2}\|Y^{k+1} - Y^k\|^2_F. \] (50)

Substituting (50) into (49), we get
\[ \|w^{k+1} - w^*\|^2_G \leq \|w^k - w^*\|^2_G \left( w^k - w^{k+1}, M \left( w^k - w^{k+1} \right) \right). \] (51)

Thus, the proof is completed. \[ \square \]

Based on the Theorem 3, we get the following lemma.

**Lemma 4.** Let \{\(w^k\)\} be the sequence generated by applying proximal ADM to problem (18)-(19), \(w^* \in \mathbb{R}^n\) any solution to problem (18)-(19), \(r > -1/2\), and \(s > -1/2\); then one has the following:

1. The sequence \(\|w^k - w^*\|^2_G\) is nonincreasing;
2. The sequence \(\{w^k\}\) is bounded;
3. \(\lim_{k \to \infty} \|w^{k+1} - w^*\|^2_F = 0\);
4. \(G\) and \(M\) are both symmetric positive-definite matrices.

Proof. Since
\[ \begin{pmatrix} \frac{1}{2} + s + \beta & 0 \\
0 & \frac{1}{\beta} \end{pmatrix} I_n - \begin{pmatrix} I_n & -I_n \\
-I_n & \frac{1}{\beta} I_n \end{pmatrix} = \begin{pmatrix} (1/2 + s) I_n & 0 \\
0 & \frac{1}{\beta} I_n \end{pmatrix}, \] (52)

it is easy to check that if \(r > -1/2, s > -1/2\), then \(G\) and \(M\) are symmetric positive-definite matrices.

Let \(\tau > 0\) be the smallest eigenvalue of matrix \(M\). Then, from (46), we have
\[ \|w^{k+1} - w^*\|^2_G \leq \|w^k - w^*\|^2_G - \tau \|w^k - w^{k+1}\|^2_F. \] (53)

Following (53), we immediately have \(\|w^k - w^*\|^2_G\) is nonincreasing and thus the sequence \(\{w^k\}\) is bounded. Moreover, we have
\[ \|w^{k+1} - w^*\|^2_G \leq \|w^0 - w^*\|^2_G - \tau \sum_{j=0}^{k} \|w^j - w^{j+1}\|^2_F. \] (54)

So, we get
\[ \sum_{j=0}^{k} \|w^j - w^{j+1}\|^2_F < \infty, \quad \forall k > 0, \] (55)

then
\[ \lim_{k \to \infty} \|w^k - w^{k+1}\|^2_F = 0. \] (56)

Thus, the proof is completed. \[ \square \]

Following Lemma 4, now we are in the stage of giving the main convergence results of proximal ADM with \(r > -1/2\) and \(s > -1/2\) for problem (18)-(19).

**Theorem 5.** Let \(\{w^k\}\) be the sequence generated by applying proximal ADM to problem (18)-(19), \(r > -1/2, s > -1/2\); then \(\{w^k\}\) converges to a solution point of (18)-(19).

Proof. Since the sequence \(\{w^k\}\) is bounded (see point (2) of Lemma 4), it has at least one cluster point. Let \(w^{\infty}\) be a cluster point of \(\{w^k\}\) and the subsequence \(\{w^{k+}\}\) converges to \(w^{\infty}\). It follows from (33) that
\[ \lim_{j \to \infty} \left< X^t - X^{k+1}, X^{k+1} - C - \Lambda_{k+1} - \beta(Y^k - Y^{k+1}) + r(X^{k+1} - X^k) \right> \geq 0, \]
Example 6. In the first numerical experiment, we set the $C_i$ as an $n \times n$ matrix whose entries are generated randomly in $[-1, 1]$. Let $C = (C_1 + C_1^T)/2$ and further let the diagonal elements of $C$ be 1 that is, $C_{ii} = 1, i = 1, 2, \ldots, n$. In this test example, we simply let $S_0$ be in the form of (31) and let $H_L = \left((l_{ij})\right) \in \mathbb{R}^{n\times n}$,

\[ l_{ij} = \begin{cases} 
-0.5, & i \neq j \\
1, & i = j, 
\end{cases} \quad i, j = 1, 2, \ldots, n, \]

\[ H_U = \left((u_{ij})\right) \in \mathbb{R}^{n\times n}, \]

\[ u_{ij} = \begin{cases} 
0.5, & i \neq j \\
1, & i = j, 
\end{cases} \quad i, j = 1, 2, \ldots, n. \]

Moreover, let $X^0 = \text{eye}(n), Y^0 = \text{eye}(n), \Lambda^0 = \text{zeros}(n)$, $\beta = 4$, and $\epsilon = 10^{-6}$, where $\text{eye}(n)$ and $\text{zeros}(n)$ are both the Matlab functions. For different problem size $n$ and different proximal parameters $r$ and $s$, Table 1 shows the computational results. There, we report the number of iterations (It.) and the computing time in seconds (CPU.) it takes to reach convergence. The stopping criterion of the proximal ADM is

\[ \|w^{k+1} - w^k\|_{\max} < \epsilon, \] (63)

where $\|X\|_{\max} = \max(\max(\text{abs}(X)))$ is the maximum absolute value of the elements of the matrix $X$.

Remark 7. Note that if the proximal parameters are equal to zero, that is, $r = 0$ and $s = 0$, then the proximal ADM is the classical ADM.

Example 8. All the data are the same as in Example 6 except that $C_1$ is an $n \times n$ matrix whose entries are generated randomly in $[-1000, 1000]$, let $H_L = \left((l_{ij})\right) \in \mathbb{R}^{n\times n}$,

\[ l_{ij} = \begin{cases} 
-500, & i \neq j \\
1000, & i = j, 
\end{cases} \quad i, j = 1, 2, \ldots, n, \]

\[ H_U = \left((u_{ij})\right) \in \mathbb{R}^{n\times n}, \]

\[ u_{ij} = \begin{cases} 
500, & i \neq j \\
1000, & i = j, 
\end{cases} \quad i, j = 1, 2, \ldots, n. \]

The computational results are reported in Table 2.

Example 9. Let $S_0$ be in the form of (31) and $l_{ij} = 0, u_{ij} = +\infty$, $i, j = 1, 2, \ldots, n$. Assume that $C$, $X_0$, $Y_0$, $\Lambda_0$, $\beta$, $\epsilon$, and the stopping criterion are the same as those in Example 6, but the diagonal elements of matrix $C$ are replaced by

\[ C_{ii} = \alpha + (1 - \alpha) \times \text{rand}, \quad i = 1, 2, \ldots, n, \] (65)

where $\alpha \in (0, 1)$ is a given number, rand is the Matlab function generating a number randomly in $[0, 1]$. In the following numerical experiments, we let $\alpha = 0.2$. For different problem size $n$ and different proximal parameters $r$ and $s$, Table 3 shows the number of iterations and the computing time in seconds it takes to reach convergence.

### Table 1: Numerical results of Example 6.

| $n$  | $r = -0.3, s = -0.3$ | $r = 0, s = 0$ | $r = 3, s = 3$ |
|------|---------------------|----------------|----------------|
|      | It. | CPU. | It. | CPU. | It. | CPU. |
| 100  | 31  | 0.292 | 34  | 0.331 | 72  | 0.764 |
| 200  | 33  | 1.346 | 39  | 1.570 | 84  | 3.364 |
| 300  | 38  | 4.265 | 41  | 5.746 | 90  | 9.991 |
| 400  | 40  | 9.872 | 43  | 9.919 | 94  | 22.03 |
| 500  | 39  | 15.83 | 45  | 18.39 | 98  | 39.91 |

Following point (3) of Lemma 4, we have

\[ \lim_{j \to \infty} \langle X^j - X^\infty, X^\infty - C - \Lambda^\infty \rangle \geq 0, \quad \forall X^j \in \mathcal{W}, \]

\[ X^\infty = 0. \]

This means that $w^\infty$ is a solution point of (18)-(19). Since $\{w^k\}$ converges to $w^\infty$, we have that, for any given $\epsilon > 0$, there exists an integer $N > 0$ such that

\[ \|w^k - w^\infty\|^2_{G} < \epsilon, \quad \forall k \geq N. \] (59)

Furthermore, using the inequality (53), we have

\[ \|w^k - w^\infty\|^2_{G} < \|w^j - w^\infty\|^2_{G}, \quad \forall k \geq k_j. \] (60)

Combining (59) and (60), we get that

\[ \|w^k - w^\infty\|^2_{G} < \epsilon, \quad \forall k > N. \] (61)

This implies that the sequence $\{w^k\}$ converges to $w^\infty$. So the proof is completed. \(\square\)

### 5. Numerical Experiments

In this section, we implement the proximal ADM to solve the problem (1) and show the numerical performances of proximal ADM with different proximal parameters. Additionally, we compare the classical ADM (i.e., the proximal ADM with proximal parameters $r = 0$ and $s = 0$) with the alternating projections method proposed by Higham [6] numerically and show that the alternating projections method is not equivalent to proximal ADM with zero proximal parameters. All the codes were written in Matlab 7.1 and run on IBM notebook PC R400.
Example 11. Let $C_i$ be an $n \times n$ matrix whose entries are generated randomly in $[-0.5,0.5]$, $C = (C_1 + C_1^T)/2$, and let the diagonal elements of $C$ be 1. And let

$$S_B = \{ X \in R^{n \times n} \mid X = X^T, X_{ij} = e_{ij}, (i,j) \in B_c, X_{ij} \geq l_{ij}, (i,j) \in B_e, \quad X_{ij} \leq u_{ij}, (i,j) \in B_u \},$$

where $B_c, B_e, B_u$ be subsets of $\{(i,j) \mid 1 \leq i, j \leq n\}$ denoting the indexes of such entries of $X$ that are constrained by equality, lower bounds, and upper bounds, respectively. In this test example, we let the index sets $B_c, B_e, B_u$ be the same as in Example 5.4 of [3]; that is, $B_c = \{(i,i) \mid i = 1,2,\ldots,n\}$ and $B_e, B_u \subset \{(i,j) \mid 1 \leq i < j \leq n\}$ consist of the indices of $\min(n,n-i)$ randomly generated elements at the $i$th row of $X$, $i = 1, 2, \ldots, n$ with $\bar{n}_c = 5$ and $\bar{n}_e = 10$, respectively. We take $e_{ij} = 1$ for $(i,j) \in B_e$, $l_{ij} = -0.1$ for $(i,j) \in B_e$, and $u_{ij} = 0.1$ for $(i,j) \in B_u$.

Moreover, let $X_0, Y_0, \Lambda, \beta, \epsilon$, and the stopping criterion be the same as those in Example 6. For different problem size $n$, different proximal parameters $r$ and $s$, and different values of $\bar{n}_e$, Tables 5(a) and 5(b) show the number of iterations and the computing time in seconds it takes to reach convergence, respectively.

Numerical experiments show that the proximal ADM with relaxed parameters is convergent. Moreover, we draw the conclusion that the proximal ADM with smaller value of proximal parameters generally converges more quickly than the proximal ADM with comparatively larger value of proximal parameters to solve the problem (1).

Example 12. In this test example, we apply the proximal ADM with $r = 0, s = 0$ (i.e., the classical ADM) to solve the nearest correlation matrix problem, that is, problem (1) with $S_B$ in the form of (5), and compare the classical ADM numerically with the alternating projections method (APM) [6]. The APM computes the nearest correlation matrix to a symmetric $C \in R^{n \times n}$ by the following process:

$$\Delta S_0 = 0, Y_0 = C;$$

for $k = 1, 2, \ldots$,

$$R_k = Y_{k-1} - \Delta S_{k-1};$$

$$X_k = P_{S_k}(R_k);$$

$$\Delta S_k = X_k - R_k;$$

$$Y_k = P_{S_k}(X_k);$$

end.

In this numerical experiment, the stopping criterion of the APM is

$$\max \{ \| X_k - X_{k-1} \|_{\max}, \| Y_k - Y_{k-1} \|_{\max}, \| X_k - Y_k \|_{\max} \} < \epsilon.$$

(67)

Let the matrix $C$ and the initial parameters of classical ADM be the same as those in Example 6. Table 6(a) reports the numerical performance of proximal ADM and the APM for computing the nearest correlation matrix to $C$.

| $n$   | $r = -0.3, s = -0.3$ | $r = 0, s = 0$ | $r = 3, s = 3$ |
|-------|----------------------|----------------|----------------|
|       | It. | CPU. | It. | CPU. | It. | CPU. |
| 100   | 22  | 0.293| 25  | 0.354| 34  | 0.448|
| 200   | 25  | 2.119| 28  | 2.425| 40  | 3.436|
| 300   | 27  | 7.141| 30  | 8.024| 44  | 11.64|
| 400   | 29  | 17.40| 31  | 18.59| 46  | 27.32|
| 500   | 30  | 34.17| 33  | 37.45| 48  | 53.84|

| $n$   | $r = -0.3, s = -0.3$ | $r = 0, s = 0$ | $r = 1, s = 1$ |
|-------|----------------------|----------------|----------------|
|       | It. | CPU. | It. | CPU. | It. | CPU. |
| 100   | 22  | 0.293| 25  | 0.354| 34  | 0.448|
| 200   | 25  | 2.119| 28  | 2.425| 40  | 3.436|
| 300   | 27  | 7.141| 30  | 8.024| 44  | 11.64|
| 400   | 29  | 17.40| 31  | 18.59| 46  | 27.32|
| 500   | 30  | 34.17| 33  | 37.45| 48  | 53.84|

Example 10. All the data are the same as in Example 9 except that $\alpha = 0$. The computational results are reported in Table 4.
Further, let $C_j$ be an $n \times n$ matrix whose entries are generated randomly in $[0, 1]$ and $C = (C_j + C_j^T)/2$. The other data are the same as above. Table 6(b) reports the numerical performance of the classical ADM and the APM for computing the nearest correlation matrix to the matrix $C$. Numerical experiments show that the classical ADM generally exhibits a better numerical performance than the APM for the test problems above.

6. Conclusions

In this paper, we apply the proximal ADM to a class of matrix optimization problems and find that the restriction of proximal parameters can be relaxed. Moreover, numerical experiments show that the proximal ADM with relaxed parameters generally has a better numerical performance in solving the matrix optimization problem than the classical proximal alternating direction method.

Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.

The paper is concerned with the dynamic oligopolistic market equilibrium problem in the realistic case in which we allow the presence of capacity constraints and production excesses and, moreover, we assume that the production function depends not only on the time but also on the equilibrium distribution. As a consequence, we introduce the generalized dynamic Cournot-Nash principle in the elastic case and prove the equivalence between this equilibrium definition and a suitable evolutionary quasi-variational inequality. For completeness we make the analysis of existence, regularity, and sensitivity of the solution. In the end, a numerical example is provided.

1. Introduction

The aim of the paper is to improve the results obtained in [1] concerning the dynamic oligopolistic market equilibrium problem in presence of production excesses by introducing the dependence on the equilibrium commodity shipment in the production function (see \(K^*(x^*)\) in (4)) and, as a consequence, studying the so-called elastic model. This is a more realistic situation since it is reasonable to think that the production function is influenced not only by the time, but also by the evaluation of the amount of commodity shipment, namely, the forecasted equilibrium solution. The presence of production excesses may be well justified in periods of economic crisis, so it is possible that some of the amounts of the commodity available are sold out whereas for a part of the products, an excess of production can occur.

In the last decade a lot of problems considering a feasible set depending on equilibrium solutions have been studied (see, e.g., [2–4]). It is well known that the equilibrium models with fixed constraint sets may be expressed in terms of evolutionary variational inequalities, while models with elastic constraint sets are expressed by evolutionary quasi-variational inequalities. Moreover, the dependence on time leads to considering variational and quasi-variational inequalities in an infinite dimensional setting, for example, a Lebesgue space.

Let us remember that a dynamic oligopolistic market equilibrium problem is the problem of finding a trade equilibrium in a supply-demand market between a finite number of spatially separated firms producing homogeneous goods in a fixed time interval. Moreover, the firms act in a noncooperative behavior. This problem has its origin with Cournot [5]. He considered only two firms and for this reason it was called the duopoly problem. Later, Nash [6, 7] extended Cournot’s duopoly problem to \(n\) agents. A more complete and efficient study was done by Nagurney et al. in [8–11], but the problem was still faced in a static case through a finite dimensional variational approach. Finally, in [12] the time dependence was considered in the model. It allows to explore the change of behavior of equilibrium states for the oligopolistic market models over a finite time interval of interest. As Beckmann and Wallace stressed, for the first time, in [13], “the time-dependent formulation of equilibrium problems allows one to explore the dynamics of adjustment processes in which a delay on time response is operating.” Of course a delay on time response always happens because the processes do not have an infinite speed. Usually, such adjustment processes can be represented by means of a memory term which depends
on previous equilibrium solutions according to the Volterra operator (see, e.g., [14, 15]).

Furthermore, in [16] the authors describe the behavior of the market by using the Lagrange multipliers of the infinite dimensional duality theory developed in [17–21]. Such results make use of the notion of tangent cone, normal cone, and quasi-relative interior of sets (see [22, 23]), important tools to overcome the difficulty of the emptiness of the topological interior of the ordering cone which defines constraints of several infinite dimensional problems (see [24, 25]). Moreover, a sensitivity result has been obtained which states that, under additional assumptions, small changes of the solution happen in correspondence with small changes of the profit function.

Lately, in [1, 26], the model presented in [12] has been improved with the addition of production excesses and both production and demand excesses, respectively. Another important question is to find some regularity properties for the solution. In [1, 26], the continuity of solution is proved under suitable assumptions, and it results to be very helpful in order to introduce numerical schemes to compute equilibrium solutions (see [27, 28]).

In [29, 30], the authors abandon the study of the problem from a producer’s point of view whose purpose is to maximize his own profit and focus their attention on the policy-maker’s perspective whose aim is to control the commodity exportations by means of the imposition of taxes or incentives and formulate the resulting optimization problem as an inverse variational inequality.

This paper is structured as follows. In Section 2 we present the dynamic oligopolistic market equilibrium problem with the elastic production function and after that we give the definition of equilibrium according to the generalized Cournot-Nash principle. Moreover, we prove the equivalence with a suitable evolutionary quasi-variational inequality. Section 3 is devoted to prove a result of existence of the solution, while in Section 4 Kuratowski’s set convergence will be a preliminary property in order to prove the continuity of the equilibrium solution. In Section 5 we establish a sensitivity result that shows how the equilibrium solution can change if the data have been perturbed. In Section 6 a numerical example is provided to make the theoretical model presented in the previous sections more clearer.

2. Quasi-Variational Inequalities in Dynamic Oligopolistic Markets

Let us consider $m$ firms $P_i$, $i = 1, \ldots, m$, that produce a homogeneous commodity and $n$ demand markets $Q_j$, $j = 1, \ldots, n$, that are generally spatially separated. Assume that the homogeneous commodity, produced by the $m$ firms and consumed by the $n$ markets, is involved during a time interval $[0, T]$, $T > 0$.

Let $x_{ij}(t)$, $i = 1, \ldots, m$ and $j = 1, \ldots, n$, denote the nonnegative commodity shipment between the supply market $P_i$ and the demand market $Q_j$ at the time $t \in [0, T]$. In particular, let us set the vector $x_i(t) = (x_{i1}(t), \ldots, x_{in}(t))$, $i = 1, \ldots, m$ and $t \in [0, T]$, as the strategy vector for the firm $P_i$.

Let us group the commodity shipments into a matrix function $x : [0, T] \to \mathbb{R}^{m \times n}$ and suppose that $x \in L^2([0, T], \mathbb{R}^{m \times n})$. Furthermore, we assume that the nonnegative commodity shipment $x_{ij}$ between the producer $P_i$ and the demand market $Q_j$ has to satisfy time-dependent constraints, namely, there exist two nonnegative functions $\underline{x}_i, \overline{x}_i : [0, T] \to \mathbb{R}^+$ such that

$$0 \leq x_{ij}(t) \leq \underline{x}_i(t), \quad \forall i = 1, \ldots, m,$$

$$\forall j = 1, \ldots, n,$$ a.e. in $[0, T],$$

and suppose that $\underline{x}_i, \overline{x}_i \in L^2([0, T], \mathbb{R}^+)$. Let us denote

$$D = \left\{ x \in L^2([0, T], \mathbb{R}^{m \times n}) : \underline{x}_i(t) \leq x_{ij}(t) \leq \overline{x}_i(t), \right.$$ \hfill (1)

$$\forall i = 1, \ldots, m,$$

$$\forall j = 1, \ldots, n,$$ a.e. in $[0, T] \right\}. \hfill (2)$$

It is easy to verify that $D$ is a nonempty, compact, and convex subset of $L^2([0, T], \mathbb{R}^{m \times n})$. Let $p_i(t, x(t))$, $i = 1, \ldots, m$, denote the nonnegative commodity output produced by firm $P_i$ at the time $t \in [0, T]$. Let us group the production output into a vector function $p : [0, T] \times D \to \mathbb{R}^m$ and let us suppose that $p \in L^2([0, T] \times D, \mathbb{R}^m)$.

Now, let us introduce the production excesses. Let $e_i(t)$, $i = 1, \ldots, m$, be the nonnegative production excess for the commodity of the firm $P_i$ at the time $t \in [0, T]$. Let us group the production excess into a vector function $e : [0, T] \to \mathbb{R}^m$ and let us assume that $e \in L^2([0, T], \mathbb{R}^m)$.

We consider a formulation of equilibrium problems where the dependence of the production on the unknown solution $x^*$ is in the average sense with respect to the time; namely, the following feasibility condition holds:

$$\sum_{j=1}^n x_{ij}(t) + e_i(t) = \frac{1}{T} \int_0^T p_i(t, x^*(r)) \, dr,$$ \hfill (3)

$$i = 1, \ldots, m,$$ a.e. in $[0, T]$.

Hence, condition (3) states that the average of the quantity produced by each firm $P_i$ in the time interval $[0, T]$, must be equal to the commodity shipments from that firm to all the demand markets plus the production excess, at the time $t \in [0, T]$. In fact, the production is supposed to depend on the firms’ evaluation of the commodity shipments. So one can expect the producers not to evaluate the market practicability instantly, but by an average with respect to the whole time interval.
The set of feasible vectors \((x,\epsilon) \in L^2([0,T], \mathbb{R}^{mn+m})\) is then given by the set-valued map \(K : D \rightarrow 2^{L^2([0,T], \mathbb{R}^{mn+m})}\) defined as:
\[
K^* (x^*) = \left\{ (x,\epsilon) \in L^2 ([0,T], \mathbb{R}^{mn+m}) : \right. \\
x_{ij} (t) \leq x_{ij} (t) \leq \overline{x}_{ij} (t), \quad \forall i = 1, \ldots, m, \\
\forall j = 1, \ldots, n, \quad \text{a.e. in } [0,T], \\
\sum_{j=1}^{n} x_{ij} (t) + \epsilon_{i} (t) = \frac{1}{T} \int_{0}^{T} p_{i} (t, x^* (\tau)) \, d\tau, \\
\forall i = 1, \ldots, m, \quad \text{a.e. in } [0,T], \quad \epsilon_{i} (t) \geq 0, \\
\forall i = 1, \ldots, m, \quad \text{a.e. in } [0,T] \left. \right\}. 
\]

Moreover, let us associate with each firm \(P_i\) a production cost \(f_i^*, \ i = 1, \ldots, m\), and assume that the production cost of a firm \(P_i\) may depend upon the entire production pattern; namely,
\[
f_i^* = f_i^* (t, x (t), \epsilon (t)).
\] (5)

Similarly, let us associate with each demand market \(Q_j\) a demand price for unity of the commodity \(d_j, j = 1, \ldots, n\), and assume that the demand price of a demand market \(Q_j\) may depend, in general, upon the entire consumption pattern; namely,
\[
d_j = d_j (t, x (t)).
\] (6)

Let \(g_i^*, i = 1, \ldots, m\), denote the storage cost of the commodity produced by the firm \(P_i\) and assume that this cost may depend upon the entire production pattern; namely,
\[
g_i^* = g_i^* (t, x (t), \epsilon (t)).
\] (7)

Finally, let \(c_{ij}, i = 1, \ldots, m\) and \(j = 1, \ldots, n\), denote the transaction cost, which includes the transportation cost associated with trading the commodity between firm \(P_i\) and demand market \(Q_j\). Here we permit the transaction cost to depend upon the entire shipment pattern; namely,
\[
c_{ij} = c_{ij} (t, x (t)).
\] (8)

Hence, we have the following mappings:
\[
f^* : [0,T] \times L^2 ([0,T], \mathbb{R}^m) \\
\times L^2 ([0,T], \mathbb{R}^m) \rightarrow L^2 ([0,T], \mathbb{R}^m),
\]
\[
d : [0,T] \times L^2 ([0,T], \mathbb{R}^m) \rightarrow L^2 ([0,T], \mathbb{R}^m),
\]
\[
g^* : [0,T] \times L^2 ([0,T], \mathbb{R}^m) \\
\times L^2 ([0,T], \mathbb{R}^m) \rightarrow L^2 ([0,T], \mathbb{R}^m),
\]
\[
c : [0,T] \times L^2 ([0,T], \mathbb{R}^m) \rightarrow L^2 ([0,T], \mathbb{R}^m).
\] (9)

The profit \(v_i^* (t, x(t), \epsilon(t)), i = 1, \ldots, m\), of the firm \(P_i\) at the time \(t \in [0,T]\) is, then,
\[
v_i^* (t, x(t), \epsilon(t)) = \sum_{j=1}^{n} d_j (t, x(t)) x_{ij} (t) - f_i^* (t, x(t), \epsilon(t)) - \sum_{j=1}^{n} c_{ij} (t, x(t)) x_{ij} (t);
\] (10)

namely, it is equal to the price that the demand markets are disposed to pay minus the production costs, the storage costs, and the transportation costs.

By virtue of (3), we can express the nonnegative production excess \(e_{i}(t)\) at the time \(t \in [0,T]\) in terms of the integral average of the production function and the commodity shipment. As a consequence, we get
\[
\sum_{j=1}^{n} x_{ij} (t) \leq \frac{1}{T} \int_{0}^{T} p_{i} (t, x^* (\tau)) \, d\tau, \\
\forall i = 1, \ldots, m, \quad \text{a.e. in } [0,T].
\] (11)

Then, the production costs and the storage costs, by virtue of (5) and (7), respectively, become
\[
f_i (t, x (t)) = f_i^* (t, x (t), \epsilon (t)), \\
g_i (t, x (t)) = g_i^* (t, x (t), \epsilon (t)),
\] (12)

and, analogously, the profit (10) becomes
\[
v_i (t, x (t)) = v_i^* (t, x (t), \epsilon (t)) = \sum_{j=1}^{n} d_j (t, x(t)) x_{ij} (t) - f_i (t, x(t)) - g_i (t, x(t)) - \sum_{j=1}^{n} c_{ij} (t, x(t)) x_{ij} (t).
\] (13)

As a consequence, the set of feasible vectors \(x \in L^2 ([0,T], \mathbb{R}^{mn})\) becomes the set-valued map \(K : D \rightarrow 2^{L^2 ([0,T], \mathbb{R}^{mn})}\), defined as
\[
K^* (x^*) = \left\{ x \in L^2 ([0,T], \mathbb{R}^{mn}) : \\
x_{ij} (t) \leq x_{ij} (t) \leq \overline{x}_{ij} (t), \quad \forall i = 1, \ldots, m, \\
\forall j = 1, \ldots, n, \quad \text{a.e. in } [0,T], \\
\sum_{j=1}^{n} x_{ij} (t) \leq \frac{1}{T} \int_{0}^{T} p_{i} (t, x^* (\tau)) \, d\tau, \\
\forall i = 1, \ldots, m, \quad \text{a.e. in } [0,T] \right\}. 
\] (14)
Let us denote $x_i = \{x_{ij}\}_{j=1,...,n}, i = 1,...,m$, and $\nabla_D v = (\partial v_j / \partial x_{ij})_{j=1,...,n}$. Let us assume the following assumptions:

(i) $v_i(t, x(t))$ is continuously differentiable for each $i = 1,...,m$, a.e. in $[0,T],$

(ii) $\nabla_D v = (\partial v_j / \partial x_{ij})_{j=1,...,m}$ is a Carathéodory function, such that

$$\exists y \in L^2([0,T]): \|\nabla_D v(t,x)\|_{\mathbb{R}^n} \leq y(t) + \|x\|_{\mathbb{R}^n},$$

$$\forall x \in \mathbb{R}^n, \text{ a.e. in } [0,T],$$

(iii) $v_i(t, x(t))$ is pseudoconcave with respect to the variables $x_i, i = 1,...,m$, a.e. in $[0,T].$

For the reader's convenience, we recall that a function $v$, continuously differentiable, is called pseudoconcave with respect to $x_i, i = 1,...,m$, a.e. in $[0,T]$ (see [31]), if the following holds a.e. in $[0,T]:$

$$\langle \nabla_D v_i(t,x_1,...,x_i,...,x_m), x_i - y_i \rangle$$

$$= \sum_{j=1}^n \frac{\partial v_i(t,x)}{\partial x_{ij}} (x_{ij} - y_{ij}) \geq 0$$

$$= v_i(t,x_1,...,x_i,...,x_m)$$

$$\geq v_i(t,x_1,...,x_i,...,x_m).$$

Moreover, we recall that in the Hilbert space $L^2([0,T], \mathbb{R}^k)$, we define the canonical bilinear form on $L^2([0,T], \mathbb{R}^k \times L^2([0,T], \mathbb{R}^k))$ by

$$\langle \phi, w \rangle := \int_0^T \langle \phi(t), w(t) \rangle \, dt,$$

where $\phi \in (L^2([0,T], \mathbb{R}^k))^* = L^2([0,T], \mathbb{R}^k)$, $w \in L^2([0,T], \mathbb{R}^k)$, and

$$\langle \phi(t), w(t) \rangle = \sum_{i=1}^k \phi_i(w(t)).$$

Now, let us consider the dynamic oligopolistic market, in which the $m$ firms supply the commodity in a noncooperative fashion, each one trying to maximize its own profit at the time $t \in [0,T]$. We seek to determine a nonnegative commodity distribution matrix function $x^*$ for which the $m$ firms and the $n$ demand markets will be in a state of equilibrium according to the dynamic Cournot-Nash principle.

**Definition 1.** $x^* \in K(x^*)$ is a dynamic oligopolistic market equilibrium in presence of production excesses if and only if for each $i = 1,...,m$ and a.e. in $[0,T]$

$v_i(t,x^*(t)) \geq v_i(t,x_i(t), \widehat{x}_i^*(t)), \quad \text{a.e. in } [0,T],$

where $x_i(t) = (x_{ij}(t),...,x_{in}(t))$ and $\widehat{x}_i^*(t) = (x_{1j}^*(t),...,x_{ij}^*(t),...,x_{nj}^*(t))$, for $i = 1,...,m$, a.e. in $[0,T].$

**Definition 1.** States that each firm $P_i$ maximizes its own profit, at the time $t \in [0,T]$, considering the given optimal strategy $\widehat{x}_i^*(t)$ of the other firms.

**Theorem 2.** Suppose that assumptions (i), (ii), and (iii) are satisfied. Then, $x^* \in K(x^*)$ is a dynamic oligopolistic market equilibrium according to **Definition 1** if and only if it satisfies the evolutionary quasi-variational inequality

$$\int_0^T \sum_{i=1}^m \sum_{j=1}^n \frac{\partial v_i(t,x^*_j(t))}{\partial x_{ij}} (x_{ij}(t) - x^*_j(t)) \, dt \geq 0$$

$$\forall x \in K(x^*).$$

**Proof.** First of all, let us prove that the evolutionary quasi-variational inequality (20), that we can write as follows:

$$\int_0^T \sum_{i=1}^m \sum_{j=1}^n - \frac{\partial v_i(t,x^*_j(t))}{\partial x_{ij}} (x_{ij}(t) - x^*_j(t)) \, dt$$

$$= \langle -\nabla_D v(x^*), x - x^* \rangle$$

$$\int_0^T \langle -\nabla_D v(t,x^*_j(t)), x_j(t) - x^*_j(t) \rangle \, dt \geq 0$$

$$\forall x \in K(x^*),$$

is equivalent to the following point-to-point quasi-variational inequality:

$$\langle -\nabla_D v(t,x^*_j(t)), x_j(t) - x^*_j(t) \rangle$$

$$= \sum_{i=1}^m \sum_{j=1}^n - \frac{\partial v_i(t,x^*_j(t))}{\partial x_{ij}} (x_{ij}(t) - x^*_j(t)) \geq 0$$

$$\forall x(t) \in K(t,x^*), \text{ a.e. in } [0,T],$$

where

$$K(t,x^*) = \left\{ x(t) \in \mathbb{R}^n_{\geq 0} : x_{ij}(t) \leq x^*_j(t), \right\}$$

$$\forall i = 1,...,m, \forall j = 1,...,n,$$

$$\sum_{j=1}^n x_{ij}(t) \leq \frac{1}{T} \int_0^T p_i(t,x^*(r)) \, dr,$$

$$\forall i = 1,...,m.$$ 

In fact, let us suppose by absurdum that (22) does not hold, namely, $\exists x(t) \in K(x^*), \exists I \subseteq [0,T]$ with $m(I) > 0$ such that

$$\langle -\nabla_D v(t,x^*_j(t)), x(t) - x^*_j(t) \rangle < 0 \quad \text{a.e. in } I.$$ 

Let us choose, now,

$$x(t) = \begin{cases} x^*(t), & \text{in } [0,T] \setminus I, \\ \overline{x}(t), & \text{in } I. \end{cases}$$

$$\forall i = 1,...,m.$$
Hence, let us consider
\[
\langle -\nabla_D v(t, x^*(t)), x - x^* \rangle
= \int_{[0,T]} \langle -\nabla_D v(t, x^*(t)), x(t) - x^* \rangle \, dt
+ \int_I \langle -\nabla_D v(t, x^*(t)), \bar{x}(t) - x^* \rangle \, dt < 0,
\]
that is a contradiction. The vice versa is immediate.

So the equivalence between the evolutionary quasi-variational inequalities (20) and (22) is proved.

Let us prove, now, the equivalence between the dynamic Cournot-Nash principle and the evolutionary quasi-variational inequality (20).

Let us suppose that \( x^* \in \mathcal{K}(x^*) \) is an equilibrium point according to Definition 1; namely,
\[
v_i(t, x^*(t)) \geq v_i(t, x(t), \bar{x}(t)) \quad \forall x(t) \in \mathcal{K}(t, x^*),
\]
a.e. in \([0,T], \forall i = 1, \ldots, m\).

For well known theorems of optimization, we have that the necessary and sufficient condition to get (27) is that for all \( i = 1, \ldots, m \), for all \( x(t) \in \mathcal{K}(t, x^*) \), a.e. in \([0,T]\),
\[
\langle -\nabla_D v_i(t, x^*(t)), x_i(t) - x_i^*(t) \rangle = \sum_{j=1}^{n} - \frac{\partial v_i(t, x^*(t))}{\partial x_{ij}} \left( x_{ij}(t) - x_{ij}^*(t) \right) \geq 0.
\]

By assumption that \( \nabla_D v_i \) is a Carathéodory function such that
\[
\exists \varphi \in L^2([0,T]) : \|\nabla_D v_i(t, x)\|_m \leq \gamma(t) + \|x\|_m, \forall x \in \mathbb{R}^m, \text{ a.e. in } [0,T],
\]
moreover, \( x \) and \( x^* \in L^2([0,T], \mathbb{R}^m) \), so we have
\[
t \mapsto \langle -\nabla_D v_i(t, x^*(t)), x_i(t) - x_i^*(t) \rangle \in L^2([0,T], \mathbb{R}).
\]

Then, we get
\[
\langle -\nabla_D v_i(t, x^*(t)), x_i - x_i^* \rangle \geq 0 \quad \forall x \in \mathcal{K}(x^*),
\]
from which, by summing up each firm \( P_i \), for \( i = 1, \ldots, m \), we obtain
\[
\sum_{i=1}^{m} \langle -\nabla_D v_i(t, x^*(t)), x - x^* \rangle = \langle -\nabla_D v(t, x^*(t)), x - x^* \rangle \geq 0 \quad \forall x \in \mathcal{K}(x^*).
\]

Vice versa, let us suppose that \( x^*(t) \) is a solution to evolutionay quasi-variational inequality (20), but not an equilibrium solution according to the dynamic Cournot-Nash principle, namely, \( \exists y^* \subseteq [0, T] \) with \( m(I) > 0 \), \( \exists y^*_i \in \{1, \ldots, m\} \) and \( \exists y_t^* \) such that
\[
v_t(y_t(t), x^*(t)) < v_t(y_t(t), \tilde{x}_t(t), x^*_t(t)) \quad \text{in } I.
\]

Since the profit function \( v_t(t, x(t)) \) is pseudoconcave with respect to \( x_t \), we get
\[
\langle -\nabla_D v_t(t, x^*(t)), x_t^*(t) - x_t^*_t(t) \rangle < 0 \quad \text{in } I.
\]

If we choose \( x \in \mathcal{K}(x^*) \) such that
\[
x_i(t) = \begin{cases} x_i^*(t) & \text{in } [0, T] \setminus I, \quad \forall i = 1, \ldots, m, \\ x_i^*(t) & \text{in } I, \quad \text{if } i \neq i_t, \\ \tilde{x}_i & \text{in } I, \quad \text{if } i = i_t,
\end{cases}
\]
then
\[
\int_0^T \langle -\nabla_D v_t(t, x^*(t)), x(t) - x^* \rangle \, dt = \int_I \langle -\nabla_D v_t(t, x^*(t)), \tilde{x}_t - x_t^*(t) \rangle \, dt < 0,
\]
so we get the contradiction. \( \square \)

3. An Existence Theorem for Equilibrium Solutions

Now, we prove an existence result for the equilibrium solution to the dynamic elastic oligopolistic market equilibrium problem. To this aim, we recall a general existence result for solutions to quasi-variational inequalities in topological linear locally convex Hausdorff spaces due to Tan [32].

**Theorem 3.** Let \( X \) be a topological linear locally convex Hausdorff space and let \( D \) be a convex compact nonempty subset of \( X \). Let \( C : D \rightarrow 2^X \) be an upper semicontinuous multivalued mapping with \( C(x), x \in D \), convex compact nonempty, let \( \mathcal{K} : D \rightarrow 2^D \) be a closed lower semicontinuous multivalued mapping with \( \mathcal{K}(x), x \in D \), convex compact nonempty, and let \( \varphi : D \rightarrow \mathbb{R} \) be a proper convex lower semicontinuous function. Then, there exists \( x^* \in D \) such that:

(i) \( x^* \in \mathcal{K}(x^*) \),

(ii) there exists \( y^* \in \mathcal{K}(x^*) \) for which
\[
\langle x - x^*, y^* \rangle + \varphi(x) - \varphi(x^*) \geq 0, \quad \forall x \in \mathcal{K}(x^*).
\]

Now, we are able to prove our main result.

**Theorem 4.** Let \( v : [0, T] \rightarrow \mathbb{R}^m \) and \( p : [0, T] \rightarrow \mathbb{R}^m \) be two vector functions such that assumptions (i) and (iii) are satisfied and
\[
\exists \varphi \in L^2([0,T]) : \|\nabla_D v(t,x)\| \leq \gamma(t) + \|x\|, \forall x \in \mathbb{R}^m, \text{ a.e. in } [0,T];
\]

(II) $p(t,x)$ is measurable in $t$, for all $x \in \mathbb{R}^m$, continuous in $x$, a.e. in $[0,T]$, such that $\exists \Phi \in L^1([0,T])$: $\|p(t,x)\| \leq \Phi(t) + \|x\|^{\beta}$, for all $x \in \mathbb{R}^m$, a.e. in $[0,T]$.

(III) $\exists \theta(t) \geq 0$, a.e. in $[0,T]$, $\eta \in L^\infty([0,T])$ such that

$$\|p(t,x_1) - p(t,x_2)\| \leq \eta(t) \|x_1 - x_2\|,$$

\[ \forall x_1, x_2 \in \mathbb{R}^m, \text{ a.e. in } [0,T]. \tag{38} \]

Then, evolutionary quasi-variational inequality (20) admits a solution.

**Proof.** At first, observe that under the hypotheses (I) and (II) and if $x \in L^2([0,T], \mathbb{R}^m)$,

$$t \mapsto \nabla Dv(t,x(t)) \in L^2([0,T], \mathbb{R}^m), \quad \tag{39}$$

$$t \mapsto p(t,x(t)) \in L^1([0,T], \mathbb{R}^m).$$

Moreover, by (I) and (II) it follows that $\nabla Dv$ and $p$ belong to the class of nemtyski operators. Therefore if $\{x^k\}_{k \in \mathbb{N}}$ is a sequence such that $x^k \to x$, in $L^2([0,T], \mathbb{R}^m)$, we have

$$\|\nabla Dv(t,x^k) - \nabla Dv(t,x)\|_{L^2} \to 0,$$

$$\|p(t,x^k) - p(t,x)\|_{L^1} \to 0,$$ \tag{40}

where the functions $\nabla Dv$ and $p$ are $L^2$- and $L^1$-continuous, respectively.

Now, in order to show that $\kappa(x^*)$ is a closed multifunction, we prove that the following condition holds. For every two arbitrary sequences $\{x^k\}_{k \in \mathbb{N}}$ and $\{y^k\}_{k \in \mathbb{N}}$ such that $x^k \to x$ and $y^k \to y$ in $L^2([0,T], \mathbb{R}^m)$, with $y^k \in \kappa(x^k)$, $\forall n \in \mathbb{N}$, then $y \in \kappa(x)$. To this aim, let us consider two arbitrary convergent sequences in $L^2([0,T], \mathbb{R}^m)$, $\{x^k\}_{k \in \mathbb{N}}$ and $\{y^k\}_{k \in \mathbb{N}}$ to $x$ and $y$, respectively. Since $y^k \in \kappa(x^k)$, $\exists \delta(t) \leq \delta(t)$, $\forall i = 1, \ldots, m$, $j = 1, \ldots, n$, and a.e. in $[0,T]$, and the convergence of the sequence $\{y^k\}_{k \in \mathbb{N}}$ in $L^2([0,T], \mathbb{R}^m)$ implies that also $y$ satisfies the capacity constraints.

Moreover, the following relationship holds:

$$\sum_{j=1}^m \delta_j(t) \leq 1 \left\{ \frac{T}{T} \right\} \int_0^T p(x, x^k(t)) \, dt, \quad \tag{41}$$

$$i = 1, \ldots, m, \text{ a.e. in } [0,T].$$

The left-hand side converges almost everywhere to $\sum_{j=1}^m \delta_j(t)$; for the right-hand side, meanwhile, $i = 1, \ldots, m$, we have

$$\sup_{[0,T]} \left\{ \int_0^T p(t, x^k(t)) \, dt \right\} \leq \sup_{[0,T]} \left\{ \int_0^T p(t, x(t)) \, dt \right\} \leq \sup_{[0,T]} \left\{ \int_0^T p(t, x^k(t)) - p(t, x(t)) \, dt \right\} \tag{42} \leq \|\eta\|_{L^\infty([0,T])} \int_0^T \|x^k(t) - x(t)\| \, dt.$$

By considering that the convergence of $\{x^k\}$ in $L^2$ implies the convergence even in $L^1$, hence the sequence $\left\{ (1/T) \int_0^T p(t, x^k(t)) \, dt \right\}_{k \in \mathbb{N}}$ converges uniformly to $(1/T) \int_0^T p(t, x(t)) \, dt$ in $L^1([0,T], \mathbb{R}^m)$.

Now, let us show the lower semicontinuity of the multifunction $\kappa$. To this aim it suffices to prove that for every $\{x^k\}_{k \in \mathbb{N}}$ such that $x^k \to x$, in $L^2([0,T], \mathbb{R}^m)$, and for every $y \in \kappa(x)$, there exists a sequence $\{y^k\}_{k \in \mathbb{N}}$ such that $y^k \to y$, in $L^2([0,T], \mathbb{R}^m)$, with $y^k \in \kappa(x^k)$, for all $k \in \mathbb{N}$.

Let $\{x^k\}_{k \in \mathbb{N}}$ be an arbitrary sequence such that $x^k \to x$, in $L^2([0,T], \mathbb{R}^m)$, and let $y \in \kappa(x)$. Let us note that, for $i = 1, \ldots, m$ and $j = 1, \ldots, n$, and if

$$a_{ij}^k(t) = y_{ij}^k(t) - x_{ij}(t) + \frac{1}{mT}$$

$$\times \left[ \int_0^T p(t, x(t)) \, dt - \int_0^T p(t, x^k(t)) \, dt \right], \tag{43}$$

we obtain, by virtue of the uniform convergence of $\left\{ (1/T) \int_0^T p(t, x^k(t)) \, dt \right\}_{k \in \mathbb{N}}$ to $(1/T) \int_0^T p(t, x(t)) \, dt$ in $L^1([0,T], \mathbb{R}^m)$, that

$$\lim_{k \to +\infty} a_{ij}^k(t) = y_{ij}(t) - x_{ij}(t) \geq 0, \quad \text{a.e. in } [0,T]. \tag{44}$$

As a consequence, there exists an index $\nu$ such that for $k > \nu$ one has, for all $i = 1, \ldots, m$, for all $j = 1, \ldots, n$,

$$a_{ij}^k(t) \geq 0, \quad \text{a.e. in } [0,T]. \tag{45}$$

Then, we consider the sequence $\{y^k\}_{k \in \mathbb{N}}$ such that

(i) for $k > \nu$, for all $i = 1, \ldots, m$, for all $j = 1, \ldots, n$, \n
$$y_{ij}^k(t) = x_{ij}(t) + \frac{1}{mT} \int_0^T p(t, x(t)) \, dt - \int_0^T p(t, x^k(t)) \, dt,$$ \tag{46} \n
where $P_{\kappa(x,k)}(\cdot)$ denotes the Hilbertian projection on $\kappa(x^k)$.

It is easy to verify that if $k \leq \nu$, for (47), $y^k \in \kappa(x^k)$. Instead, for $k > \nu$, since for (45), $\min \{x_{ij}(t) - x_{ij}(t), a_{ij}^k(t)\} \geq 0$, for all $i = 1, \ldots, m$, for all $j = 1, \ldots, n$, a.e. in $[0,T]$,

$$y_{ij}^k(t) \geq x_{ij}(t), \quad \forall i = 1, \ldots, m, \forall j = 1, \ldots, n, \text{ a.e. in } [0,T]. \tag{48}$$

Moreover, since $\min \{x_{ij}(t) - x_{ij}(t), a_{ij}^k(t)\} \leq x_{ij}(t)$, for all $i = 1, \ldots, m$, for all $j = 1, \ldots, n$, a.e. in $[0,T]$, we have

$$y_{ij}^k(t) \leq x_{ij}(t), \quad \forall i = 1, \ldots, m, \forall j = 1, \ldots, n, \text{ a.e. in } [0,T]. \tag{49}$$
Finally, we get
\[
\sum_{j=1}^{n} y_{ij}^k(t) \leq \sum_{j=1}^{n} y_{ij}(t) + \frac{1}{T} \int_{0}^{T} p_i(t, x^k(r)) \, dr - \frac{1}{T} \int_{0}^{T} p_i(t, x(r)) \, dr
\]
\[
\leq \frac{1}{T} \int_{0}^{T} p_i(t, x(r)) \, dr + \frac{1}{T} \int_{0}^{T} p_i(t, x^k(r)) \, dr - \frac{1}{T} \int_{0}^{T} p_i(t, x(r)) \, dr
\]
\[
= \frac{1}{T} \int_{0}^{T} p_i(t, x^k(r)) \, dr, \quad \forall i = 1, \ldots, m, \text{ a.e. in } [0, T].
\]

Hence, we can conclude that \( y^k \) belongs to \( \mathcal{K}(x^k) \), for all \( k \in \mathbb{N} \).

Let us prove now the convergence of \( \{ y^k \}_{k \in \mathbb{N}} \) to \( y \) in \( L^2([0, T], \mathbb{R}^m) \). Let us observe that
\[
\lim_{k \to +\infty} \min \{ x_{ij}^k(t) - x_{ij}(t), a_{ij}^k(t) \} = y_{ij}(t) - x_{ij}(t), \quad \text{ a.e. in } [0, T].
\]

As a consequence, we have that the sequence \( \{ y^k \}_{k \in \mathbb{N}} \) converges to \( y \). It is easy to show that \( \mathcal{K}(x) \) is a closed, bounded, and convex subset of \( D \) and since the space \( D \) is compact, \( \mathcal{K}(x) \), for all \( x \in D \), is compact too. As a consequence, all the hypotheses of Theorem 3 are satisfied and the existence of at least one solution is guaranteed. \( \square \)

4. Regularity Results for Equilibrium Solutions

In this section, we study the assumptions under which the continuity of solutions to evolutionary quasi-variational inequality, which expresses the equilibrium condition for the dynamic elastic oligopolistic market equilibrium problem in presence of production excesses, is ensured.

4.1. Set Convergence. First of all, we recall the notion of Kuratowski's set convergence that has an important role in order to establish regularity results. The classical notion of convergence for subsets of a given metric space \( (X, d) \) is introduced in the 1950s by Kuratowski (see [33]; see also [34, 35]).

Let \( \{ \mathcal{K}_n \}_{n \in \mathbb{N}} \) be a sequence of subsets of \( X \). Recall that
\[
d - \lim_{n} \mathcal{K}_n = \left\{ x \in X : \exists \{ x_n \}_{n \in \mathbb{N}} \text{ eventually in } \mathcal{K}_n \text{ such that } x_n \xrightarrow{d} x \right\},
\]
\[
d - \lim_{n} \mathcal{K}_n = \left\{ x \in X : \exists \{ x_n \}_{n \in \mathbb{N}} \text{ frequently in } \mathcal{K}_n \text{ such that } x_n \xrightarrow{d} x \right\},
\]
where \textit{eventually} means that there exists \( \delta \in \mathbb{N} \) such that \( x_n \in \mathcal{K}_n \) for all \( n \geq \delta \) and \textit{frequently} means that there exists an infinite subset \( N \subseteq \mathbb{N} \) such that \( x_n \in \mathcal{K}_n \) for any \( n \in N \) (in this last case, according to the notation given above, we also write that there exists a subsequence \( \{ x_{k_n} \}_{n \in \mathbb{N}} \subseteq \{ x_n \}_{n \in \mathbb{N}} \) such that \( x_{k_n} \in \mathcal{K}_{k_n} \).

In the following, we recall Kuratowski's set convergence.

**Definition 5.** We say that \( \{ \mathcal{K}_n \} \) converges to some subset \( \mathcal{K} \subseteq X \) in Kuratowski's sense and we briefly write \( \mathcal{K}_n \rightarrow \mathcal{K} \), if \( d - \lim_n \mathcal{K}_n = d - \lim_{n \rightarrow +\infty} \mathcal{K}_n = \mathcal{K} \). Thus, in order to verify that \( \mathcal{K}_n \rightarrow \mathcal{K} \), it suffices to check that

(i) \( d - \lim_{n \rightarrow +\infty} \mathcal{K}_n \subseteq \mathcal{K} \), that is, for any sequence \( \{ x_n \}_{n \in \mathbb{N}} \)

frequently in \( \mathcal{K}_n \) such that \( x_n \xrightarrow{d} x \) for some \( x \in S \), then \( x \in \mathcal{K} \);

(ii) \( \mathcal{K} \subseteq d - \lim_{n \rightarrow +\infty} \mathcal{K}_n \), that is, for any \( x \in \mathcal{K} \) there exists a sequence \( \{ x_n \}_{n \in \mathbb{N}} \)

eventually in \( \mathcal{K}_n \) such that \( x_n \xrightarrow{d} x \).

The below lemma establishes that the feasible set \( \mathcal{K} \) of the dynamic elastic oligopolistic market equilibrium problem in the presence of production excesses satisfies the property of Kuratowski's set convergence.

**Lemma 6.** Let \( x, \tilde{x} \in C^0([0, T], \mathbb{R}^m) \), let \( p \in C^0([0, T] \times \mathbb{R}^m, \mathbb{R}_+^m) \) be such that
\[
\exists \phi \in C^0([0, T], \mathbb{R}_+) : \| p(t, x) \| \leq \phi(t) \| x \|, \quad \forall x \in \mathbb{R}^m, \text{ in } [0, T],
\]

and let \( \{ t_k \}_{k \in \mathbb{N}} \) be a sequence such that \( t_k \xrightarrow{} t \), with \( t \in [0, T] \), as \( k \xrightarrow{} +\infty \). Then, the sequence of sets
\[
\mathcal{K}(t_k, x^*) = \left\{ x(t_k) \in \mathbb{R}^m : x_{ij}(t_k) \leq x_{ij}(t) \leq \tilde{x}_{ij}(t_k), \quad \forall i = 1, \ldots, m, \forall j = 1, \ldots, n, \right\}
\]
\[
\sum_{j=1}^{n} x_{ij}(t_k) \leq \frac{1}{T} \int_{0}^{T} p_i(t, x^*(r)) \, dr, \quad \forall i = 1, \ldots, m \},
\]

for all \( k \in \mathbb{N} \), converges to
\[
\mathcal{K}(t, x^*) = \left\{ x(t) \in \mathbb{R}^m : x_{ij}(t) \leq x_{ij}(t) \leq \tilde{x}_{ij}(t), \quad \forall i = 1, \ldots, m, \forall j = 1, \ldots, n, \right\}
\]
\[
\sum_{j=1}^{n} x_{ij}(t) \leq \frac{1}{T} \int_{0}^{T} p_i(t, x^*(r)) \, dr, \quad \forall i = 1, \ldots, m \},
\]

as \( k \xrightarrow{} +\infty \), in Kuratowski’s sense.
Proof. Firstly, we prove condition (K1). Let \( \{t_k\}_{k \in \mathbb{N}} \) be a sequence such that \( t_k \to t \), with \( t \in [0, T] \) as \( k \to +\infty \). Making use of the continuity assumptions on \( \varphi, \tilde{\varphi}, \) and \( p \), we get \( \varphi(t, x(t)) \to \tilde{\varphi}(t, x(t)) \), and \( p(t, y) \to p(t, y) \) as \( k \to +\infty \), respectively. Furthermore,

\[
\exists \phi \in C^0 \left( [0, T], \mathbb{R}_+ \right): \|p(t, x^*(r))\| \leq \phi(t) + \|x^*(r)\|^2,
\]

for \( t \in [0, T] \) and \( r \in [0, T] \). Since \( \phi \in C^0([0, T]) \) and \( x^* \in L^2([0, T], \mathbb{R}_+) \), then we have for \( t \in [0, T] \) and \( r \in [0, T] \)

\[
\|p(t, x^*(r))\| \leq \phi(t) + \|x^*(r)\|^2 \in L^1([0, T]),
\]

and by virtue of the continuity of \( p \) with respect to the first variable we also obtain

\[
\lim_{n \to +\infty} p(t_n, x^*(r)) = p(t, x^*(r)),
\]

for \( r \in [0, T] \) and \( x^* \in L^2([0, T], \mathbb{R}_+) \). Taking into account a well known generalization of Lebesgue’s theorem,

\[
\lim_{n \to +\infty} \int_0^r p(t_n, x^*(r)) \, dr = \int_0^r p(t, x^*(r)) \, dr,
\]

for every \( x^* \in L^2([0, T], \mathbb{R}_+) \).

Let \( x(t) \in \mathcal{K}(t, x^*) \) be fixed and let us note that, for \( i = 1, \ldots, m \) and \( j = 1, \ldots, n \), and if

\[
a_{ij} (t_k) = x_{ij} (t_k) - \bar{x}_{ij} (t_k) + \frac{1}{nT} \left[ \int_0^T p_i(t_k, x^* (t)) \, dt - \int_0^T p_i (t, x^* (t)) \, dt \right]
\]

we have

\[
\lim_{k \to +\infty} a_{ij} (t_k) = x_{ij} (t) - \bar{x}_{ij} (t) \geq 0.
\]

As a consequence, there exists an index \( \nu \) such that for \( k > \nu \), for all \( i = 1, \ldots, m \), for all \( j = 1, \ldots, n \),

\[
a_{ij} (t_k) \geq 0.
\]

As a consequence, we consider the sequence \( \{x(t_k)\}_{k \in \mathbb{N}} \) such that

(i) for \( k > \nu \), for all \( i = 1, \ldots, m \), for all \( j = 1, \ldots, n \),

\[
x_{ij} (t_k) = x_{ij} (t_k) + \min \{ x_{ij} (t_k) - \bar{x}_{ij} (t_k), a_{ij} (t_k) \},
\]

(ii) for \( k \leq \nu \), for all \( i = 1, \ldots, m \), for all \( j = 1, \ldots, n \),

\[
x_{ij} (t_k) = P_{\mathcal{K}(t_k, x^*)} x_{ij} (t_k),
\]

where \( P_{\mathcal{K}(t_k, x^*)} \) denotes the Hilbertian projection on \( \mathcal{K}(t_k, x^*) \).

Obviously if \( k \leq \nu \), for (64) we have \( x(t_k) \in \mathcal{K}(t_k, x^*) \). Instead, for \( k > \nu \), since for (62), \( \min \{ x_{ij} (t_k) - \bar{x}_{ij} (t_k), a_{ij} (t_k) \} \geq 0 \), for all \( i = 1, \ldots, m \), for all \( j = 1, \ldots, n \), we get

\[
x_{ij} (t_k) \leq x_{ij} (t_k), \quad \forall i = 1, \ldots, m, \quad \forall j = 1, \ldots, n.
\]

Moreover, since \( \min \{ x_{ij} (t_k) - \bar{x}_{ij} (t_k), \bar{x}_{ij} (t_k) - \bar{x}_{ij} (t_k), a_{ij} (t_k) \} \leq \bar{x}_{ij} (t_k) - \bar{x}_{ij} (t_k) \), for all \( i = 1, \ldots, m \), for all \( j = 1, \ldots, n \), we have

\[
x_{ij} (t_k) \leq \bar{x}_{ij} (t_k), \quad \forall i = 1, \ldots, m, \quad \forall j = 1, \ldots, n.
\]

Since

\[
\min \{ x_{ij} (t_k) - \bar{x}_{ij} (t_k), \bar{x}_{ij} (t_k) - \bar{x}_{ij} (t_k), a_{ij} (t_k) \} \leq a_{ij} (t_k) = x_{ij} (t_k) - \bar{x}_{ij} (t_k)
\]

\[
+ \left[ \frac{1}{nT} \int_0^T p_i (t_k, x^* (t)) \, dt - \int_0^T p_i (t, x^* (t)) \, dt \right]
\]

\[
\forall i = 1, \ldots, m, \quad \forall j = 1, \ldots, n,
\]

we have

\[
x_{ij} (t_k) \leq x_{ij} (t_k) + \frac{1}{nT} \left[ \int_0^T p_i (t_k, x^* (t)) \, dt - \int_0^T p_i (t, x^* (t)) \, dt \right]
\]

\[
\forall i = 1, \ldots, m, \quad \forall j = 1, \ldots, n.
\]

Then, taking into account (68), we obtain

\[
\sum_{j=1}^n x_{ij} (t_k) \leq \sum_{j=1}^n x_{ij} (t) + \frac{1}{T} \int_0^T p_i (t, x^* (t)) \, dt
\]

\[
- \frac{1}{T} \int_0^T p_i (t, x^* (t)) \, dt
\]

\[
\leq \frac{1}{T} \int_0^T p_i (t, x^* (t)) \, dt
\]

\[
+ \frac{1}{T} \int_0^T p_i (t_k, x^* (t)) \, dt
\]

\[
- \frac{1}{T} \int_0^T p_i (t, x^* (t)) \, dt
\]

\[
= \frac{1}{T} \int_0^T p_i (t_k, x^* (t)) \, dt, \quad \forall i = 1, \ldots, m.
\]
Hence, \( x(t_k) \in K(t_k, x^*) \), for all \( k \in \mathbb{N} \), and
\[
\lim_{k \to \infty} x_{ij}(t_k) = x_{ij}(t) + \min \left\{ x_{ij}(t) - \bar{x}_{ij}(t), x_{ij}(t) - x_{ij}(t) \right\}
\]
\[
= x_{ij}(t) + x_{ij}(t) - x_{ij}(t) = x_{ij}(t).
\]
(70)

Then, the proof of condition (K1) is completed.

Let us prove, now, condition (K2). Let \( \{t_k\}_{k \in \mathbb{N}} \) be a sequence such that \( t_k \to t \), with \( t \in [0, T] \), as \( k \to +\infty \).

Let \( \{x(t_k)\}_{k \in \mathbb{N}} \) be a sequence, such that \( x(t_k) \in K(t_k, x^*) \), for all \( k \in \mathbb{N} \), and converging to \( x(t) \), as \( k \to +\infty \). We have to prove that \( x(t) \in K(t, x^*) \).

Since \( x(t_k) \in K(t_k, x^*) \), for all \( k \in \mathbb{N} \),
\[
\bar{x}_{ij}(t_k) \leq x_{ij}(t_k) \leq \bar{x}_{ij}(t_k), \quad \forall j = 1, \ldots, m, \quad \forall k \in \mathbb{N},
\]
(71)

\[
\sum_{j=1}^{n} x_{ij}(t_k) \leq \frac{1}{T} \int_{0}^{T} p_j(t_k, x^*(\tau)) d\tau, \quad \forall i = 1, \ldots, m, \quad \forall k \in \mathbb{N}.
\]
(72)

Passing to the limit in (71) as \( n \to +\infty \) and taking into account the continuity assumption on the functions \( \bar{x}, \bar{x} \), and \( p \), we have
\[
x_{ij}(t) \leq x_{ij}(t) \leq \bar{x}_{ij}(t), \quad \forall j = 1, \ldots, m, \quad \forall i = 1, \ldots, n.
\]
(73)

Now, passing to the limit for \( n \to +\infty \) in the left-hand side of (72), we have
\[
\lim_{n \to +\infty} \sum_{j=1}^{n} x_{ij}(t_k) = \sum_{j=1}^{n} x_{ij}(t), \quad \forall i = 1, \ldots, m.
\]
(74)

Then, from (74) and (59), we obtain
\[
\sum_{j=1}^{n} x_{ij}(t) \leq \frac{1}{T} \int_{0}^{T} p_j(t, x^*(\tau)) d\tau, \quad \forall j = 1, \ldots, n.
\]
(75)

As a consequence,
\[
x(t) \in K(t, x^*),
\]
(76)

and, hence, condition (K2) is achieved.

\[ \square \]

### 4.2. Continuity of Solutions to Weighted Quasi-Variational Inequalities

In [2, 36–39] some continuity results for variational and quasi-variational inequalities in infinite dimensional spaces have been obtained. It is worth remarking that similar results have been proved for weighted variational and quasi-variational inequalities in nonpivot Hilbert spaces (see [4, 40]).

Now, we show a continuity result for equilibrium solutions to the dynamic elastic oligopolistic market equilibrium problem in presence of production excesses.

\[ \text{Theorem 7.} \quad \exists \phi \in C^0([0, T]) : \| p(t, x) \| \leq \phi(t) + \| x \|^2, \]
\[ \forall x \in \mathbb{R}^m, \text{ in } [0, T], \]
\[ \exists \gamma \in C^0([0, T], \mathbb{R}^m) : \| p(t, x) - p(t, x_2) \| \leq \gamma \| x_1 - x_2 \|, \]
\[ \forall x_1, x_2 \in \mathbb{R}^m, \text{ in } [0, T]. \]
(77)

Moreover, let \( \nu \in C^1([0, T] \times \mathbb{R}^m, \mathbb{R}^m) \) be a vector function satisfying assumption (iii) and such that
\[ \exists \mu > 0 : \langle -\nabla_D \nu(t, x), x - y \rangle \geq \mu \| x - y \|^2, \]
\[ \forall x, y \in \mathbb{R}^m, \text{ in } [0, T]. \]
(78)

Then the dynamic elastic market equilibrium distribution in presence of production excesses \( x^* \in K(x^*) \) is continuous in \([0, T]\).

\[ \square \]

### 5. A Sensitivity Result

In this section a theorem about the sensitivity of solution is presented. The following result establishes that a small change in profit function produces a small change in equilibrium distribution.

\[ \text{Theorem 8.} \quad \text{Assume that the profit function changes from } \nu(\cdot) \text{ to the perturbed function } \tilde{\nu}(\cdot) \text{ and denote by } x^* \text{ and } \bar{x} \text{ the corresponding solutions of the following quasi-variational inequalities:} \]
\[ \langle -\nabla_D \nu(x^*), x - x^* \rangle \geq 0, \quad \forall x \in K(x^*), \]
\[ \langle -\nabla_D \tilde{\nu}(\bar{x}), x - \bar{x} \rangle \geq 0, \quad \forall x \in K(x^*). \]
(79)

\[ \langle -\nabla_D \nu(x) + -\nabla_D \nu(y), x - y \rangle \geq \alpha \| x - y \|_{L^2([0,T],\mathbb{R}^m)}, \]
(80)

Let \( \nabla_D \nu(t, x) \) be a strongly monotone function of constant \( \alpha \), namely, for all \( x, y \in K(x^*), \exists \alpha > 0 \) such that
\[ \langle -\nabla_D \nu(x) + -\nabla_D \nu(y), x - y \rangle \geq \alpha \| x - y \|_{L^2([0,T],\mathbb{R}^m)}^2. \]
(81)

Moreover, let \( \nabla_D \nu \) be a Carathéodory function such that
\[ \exists h \in L^2([0,T]) : \| \nabla_D \nu(t, x(t)) \|_{mn} \leq h(t) + \| x(t) \|_{mn}, \quad \text{a.e. in } [0, T]. \]
(82)
Then, it follows that
\[
\|x^* - \bar{x}\|_{L^2([0,T],\mathbb{R}^{mn})} \leq \frac{1}{\alpha} \| -\nabla_D V(\bar{x}) + \nabla_D V(x^*) \|_{L^2([0,T],\mathbb{R}^{mn})}.
\] (83)

**Proof.** Choosing \(x(t) = \bar{x}(t)\) in (79) and \(x(t) = x^*(t)\) in (80), by summing up the two new inequalities, we have
\[
\langle \langle -\nabla_D V(\bar{x}) + \nabla_D V(x^*), x^* - \bar{x} \rangle \rangle \geq 0.
\] (84)

By adding and subtracting \(-\nabla_D V(\bar{x})\) in (84), we have
\[
\langle \langle -\nabla_D V(\bar{x}) + \nabla_D V(\bar{x}), x^* - \bar{x} \rangle \rangle \geq \langle \langle -\nabla_D V(x^*) + \nabla_D V(\bar{x}), x^* - \bar{x} \rangle \rangle.
\] (85)

Moreover, by using the strong monotonicity, inequality (85), and the Cauchy-Schwartz inequality, we get
\[
\begin{align*}
\alpha \|x^* - \bar{x}\|_{L^2([0,T],\mathbb{R}^{mn})}^2 &\leq \langle \langle -\nabla_D V(x^*) + \nabla_D V(\bar{x}), x^* - \bar{x} \rangle \rangle \\
&\leq \langle \langle -\nabla_D V(\bar{x}) + \nabla_D V(\bar{x}), x^* - \bar{x} \rangle \rangle \\
&\leq \| -\nabla_D V(\bar{x}) + \nabla_D V(\bar{x}) \|_{L^2([0,T],\mathbb{R}^{mn})} \\
&\times \|x^* - \bar{x}\|_{L^2([0,T],\mathbb{R}^{mn})},
\end{align*}
\] (86)

from which we get
\[
\begin{align*}
\|x^* - \bar{x}\|_{L^2([0,T],\mathbb{R}^{mn})} &\leq \frac{1}{\alpha} \| -\nabla_D V(\bar{x}) + \nabla_D V(x^*) \|_{L^2([0,T],\mathbb{R}^{mn})} \\
&\leq 1.
\end{align*}
\] (87)

**6. A Numerical Example**

This section is devoted to provide a numerical example of the theoretical achievements presented.

Let us consider two firms and two demand markets, as in Figure 1. Let \(\underline{x}, \bar{x} \in L^2([0,1], \mathbb{R}^4)\) be the capacity constraints such that, a.e. in \([0,1]\),
\[
\underline{x}(t) = \begin{pmatrix} 0 & \frac{2}{5}t \\ \frac{1}{2}t & 0 \end{pmatrix}, \quad \bar{x}(t) = \begin{pmatrix} 10t & 5t \\ 12t & 10t \end{pmatrix}.
\] (88)

Let us denote
\[
D = \left\{ x \in L^2([0,1], \mathbb{R}^4) : \underline{x}_{ij}(t) \leq x_{ij}(t) \leq \bar{x}_{ij}(t), \quad \forall i = 1, 2, \forall j = 1, 2, \text{ a.e. in } [0,1] \right\}.
\] (89)

Let \(p \in L^1([0,1] \times D, \mathbb{R}^2)\) be the production function, such that, a.e. in \([0,1]\),
\[
p(t) = \begin{pmatrix} 6t + 2x_{11}^2(t) \\ 3t + 2x_{11}^2(t) + x_{12}^2(t) \end{pmatrix}.
\] (90)

\[
\text{As a consequence, the feasible set is the set value function}
\]
\[
K(x^*) = \left\{ x \in L^2\left([0,1], \mathbb{R}^4\right) : \underline{x}_{ij}(t) \leq x_{ij}(t) \leq \bar{x}_{ij}(t), \quad \forall i = 1, 2, \forall j = 1, 2, \text{ a.e. in } [0,1], \right. \\
\left. \sum_{j=1}^2 x_{ij}(t) \leq \int_0^1 p_i(t, x^*(r)) \, dr, \quad \forall i = 1, 2, \text{ a.e. in } [0,1] \right\}.
\] (91)

Let us consider the profit function \(v \in C^1([0,1] \times D, \mathbb{R}^2)\) given by
\[
v_1(t, x(t)) = -4x_{11}^2(t) - 2x_{12}^2(t) - x_{11}(t)x_{12}(t) + 6tx_{11}(t) + 3tx_{12}(t),
\]
\[
v_2(t, x(t)) = -2x_{21}^2(t) - 2x_{12}^2(t) - 2x_{21}(t)x_{22}(t) + 6tx_{21}(t) + 5tx_{22}(t).
\] (92)

Then, the operator \(-\nabla_D v \in L^2([0,1] \times D, \mathbb{R}^4)\) is given by
\[
-\nabla_D v(t, x(t)) = \begin{pmatrix} 8x_{11}(t) + x_{12}(t) - 6t & 4x_{12}(t) + x_{11}(t) - 3t \\ 4x_{21}(t) + 2x_{22}(t) - 6t & 10x_{22}(t) + 2x_{21}(t) - 5t \end{pmatrix}.
\] (93)
The dynamic oligopolistic market equilibrium distribution in presence of the excesses is the solution to the evolutionary quasi-variational inequality:

\[
\begin{aligned}
\int_0^1 & \sum_{j=1}^2 \sum_{i=1}^2 - \frac{\partial v_j(t,x^*(t))}{\partial x_{ij}} (x_{ij}(t) - x_{ij}^*(t)) \, dt \geq 0, \\
\forall x \in K(x^*).
\end{aligned}
\] (94)

Let us observe that all the hypotheses of Theorem 4 are satisfied; hence, evolutionary quasi-variational inequality (94) admits solutions.

In order to compute a solution to (94) we make use of the direct method (see [41]). We consider the following system:

\[
\begin{align*}
8x_{11}^*(t) + x_{12}^*(t) - 6t &= 0, \\
x_{11}^*(t) + 4x_{12}^*(t) - 3t &= 0, \\
4x_{21}^*(t) + 2x_{22}^*(t) - 6t &= 0, \\
2x_{21}^*(t) + 10x_{22}^*(t) - 5t &= 0,
\end{align*}
\]

\[
x_{ij}(t) \leq x_{ij}^*(t) \leq \bar{x}_{ij}(t), \quad \forall i = 1, 2, \forall j = 1, 2, \text{a.e. in } [0,1],
\]

\[
\sum_{j=1}^2 x_{ij}^*(t) \leq \int_0^1 p_i(t,x^*(t)) \, dt, \quad \forall i = 1, 2, \text{a.e. in } [0,1],
\] (95)

and we get the following solution, a.e. in [0,1],

\[
x^*(t) = \left( \begin{array}{c}
7t \\
10t \\
25t \\
18t
\end{array} \right) \left( \begin{array}{c}
3t \\
5t \\
2t \\
9t
\end{array} \right). \] (96)

Let us observe that the solution satisfies all the constraints; in particular, if we compute

\[
\begin{align*}
\int_0^1 p_1(t,x^*(t)) \, dt &= 6t + \frac{7}{10}, \\
\int_0^1 p_2(t,x^*(t)) \, dt &= 3t + 1,
\end{align*}
\] (97)

we are able to obtain the related production excesses:

\[
e(t) = \left( \begin{array}{c}
47t + 7 \\
10 \\
25t + 18 \\
18
\end{array} \right). \] (98)

7. Conclusions

In [1] the dynamic oligopolistic market equilibrium problem was studied by introducing production excesses, and the dynamic Cournot-Nash equilibrium was characterized as a solution to a suitable evolutionary variational inequality. In this paper, in order to have a model closer to reality, it was supposed that the production function depends on the equilibrium commodity shipment. Hence, an elastic formulation was introduced that leads to an equivalent formulation by means of a suitable evolutionary quasi-variational inequality.

By means of this mathematical formulation, results of existence and regularity of solutions were proved. Furthermore, a sensitivity analysis is provided. At last a numerical example was provided in order to clarify the theoretical results. In future work, it is possible to consider also demand excesses and elastic demand function, in order to have a more complete and realistic model.

Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.

A Sharper Global Error Bound for the Generalized Nonlinear Complementarity Problem over a Polyhedral Cone

Hongchun Sun and Yiju Wang

Received 12 July 2013; Revised 17 September 2013; Accepted 30 September 2013

1. Introduction

Let \( K = \{ v \in \mathbb{R}^m \mid A v \geq 0, B v = 0 \} \) be a polyhedral cone in \( \mathbb{R}^m \) for matrices \( A \in \mathbb{R}^{s \times m}, B \in \mathbb{R}^{t \times m} \), and let \( K^o \) be its dual cone; that is,

\[
K^o = \{ u \in \mathbb{R}^m \mid u = A^\top \lambda_1 + B^\top \lambda_2, \lambda_1 \in \mathbb{R}^s_+, \lambda_2 \in \mathbb{R}^t \}.
\]

(1)

For continuous mappings \( F, G : \mathbb{R}^n \to \mathbb{R}^m \), the generalized nonlinear complementarity problem, abbreviated as GNCP, is to find vector \( x^* \in \mathbb{R}^n \) such that

\[
F(x^*) \in K, \quad G(x^*) \in K^o, \quad F(x^*)^\top G(x^*) = 0.
\]

(2)

Throughout this paper, the solution set of the GNCP, denoted by \( X^* \), is assumed to be nonempty.

The GNCP is a direct generalization of the classical nonlinear complementarity problem and a special case of the general variational inequalities problem [1]. The GNCP was deeply discussed [2–5] after the work in [6]. The GNCP plays a significant role in economics, operation research, nonlinear analysis, and so forth (see [7, 8]). For example, the classical Walrasian law of competitive equilibria of exchange economies can be formulated as a generalized nonlinear complementarity problem in the price and excess demand variables (see [8]).

For the GNCP, the solution existence and the numerical solution methods for the GNCP were discussed [2, 3, 6]. As an important tool for a mathematical problem, the global error bound estimation for GNCP with the mapping being \( \gamma \)-strongly monotone and Hölder continuous was discussed in [5], and a global error bound for the GNCP for the linear and monotonic case was established in [4].

In this paper, we will establish a global error bound for the problem (2) without the Hölder continuity of the underlying mapping. To this end, we first develop some new equivalent reformulations of the GNCP under weaker conditions and then establish a sharper global error bound for the GNCP in terms of some easier computed residual functions. The results obtained in this paper can be taken as an improvement of the existing results for GNCP and variational inequalities problem [4, 5, 9–11].

To end this section, we give some notations used in this paper. Vectors considered in this paper are taken in the Euclidean space \( \mathbb{R}^n \) equipped with the usual inner product, and the Euclidean 2-norm and 1-norm of vector in \( \mathbb{R}^n \) are, respectively, denoted by \( \| \cdot \| \) and \( \| \cdot \|_1 \). We use \( R^+ \) to denote the nonnegative orthant in \( \mathbb{R}^n \) and use \( x_+ \) and \( x_- \) to denote the vectors composed by elements \( (x_+,)_i := \max\{x_i, 0\}, (x_-)_i := \max\{-x_i, 0\}, 1 \leq i \leq n \), respectively. For simplicity, we use \( (x; y) \) to denote vector \( (x^\top, y^\top)^\top \), use \( I \) to denote the identity matrix with appropriate dimension, use \( x \geq 0 \) to denote
a nonnegative vector $x \in \mathbb{R}^n$, and use $\text{dist}(x, X^*)$ to denote
the distance from point $x$ to the solution set $X^*$.

2. Global Error Bound for the GNCP

First, we give some concepts used in the subsequent.

**Definition 1.** The mapping $F: \mathbb{R}^n \rightarrow \mathbb{R}^m$ is said to be
(i) monotone with respect to $G: \mathbb{R}^n \rightarrow \mathbb{R}^m$ if
\[
\langle F(x) - F(y), G(x) - G(y) \rangle \geq 0, \quad \forall x, y \in \mathbb{R}^n;
\]
(ii) $\gamma$-strongly $G$-monotone with respect to $G: \mathbb{R}^n \rightarrow \mathbb{R}^m$ if there are constants $c_i > 0, \gamma > 0$ such that
\[
\langle F(x) - F(y), G(x) - G(y) \rangle \geq c_i \|G(x) - G(y)\|^{1+\gamma},
\]
\[
\forall x, y \in \mathbb{R}^n.
\]

**Remark 2.** Based on this definition, $\gamma$-strongly $G$-monotone implies monotonicity, and if $F(x) = Mx + p, G(x) = Nx + q$ with $M, N \in \mathbb{R}^{m \times n}, p, q \in \mathbb{R}^m$, then the above Definition 1(i) is equivalent to that the matrix $M^T N$ is positive semidefinite.

Now, we give some assumptions for our analysis based on Definition 1.

**Assumption 3.** For mappings $F, G$ and matrix $A$ involved in the GNCP, we assume that

(A1) mapping $F$ is monotone with respect to mapping $G$;

(A2) matrix $A^T$ has full-column rank.

**Remark 4.** Under (A2) in the assumption, matrix $A^T$ has left inverse $(AA^T)^{-1} A$, that is, its pseudoinverse of $A^T$. Certainly, the assumption on matrix $A^T$ is weaker than that on matrix $(A^T, B^T)$ which has full-column rank [4]. In addition, when the mappings $F, G$ are both linear, then Assumption 3(A1) coincides with Assumption (A1) in [4].

In the following, we will establish a new equivalent reformulation to the GNCP. First, we give the following conclusion established in [2].

**Theorem 5.** A point $x^* \in \mathbb{R}^n$ is a solution of the GNCP if and only if there exist $\lambda^*_1 \in \mathbb{R}^s, \lambda^*_2 \in \mathbb{R}^r$, such that
\[
AF(x^*) \geq 0,
\]
\[
BF(x^*) = 0,
\]
\[
\lambda^*_1 \geq 0,
\]
\[
(F(x^*))^T G(x^*) = 0,
\]
\[
G(x^*) = A^T \lambda^*_1 + B^T \lambda^*_2.
\]

From Theorem 5, under Assumption 3(A2), we can transform the system into a new system in which neither $\lambda_1$ nor $\lambda_2$ is involved. To this end, we need the following conclusion [12].

**Lemma 6.** If the linear system $Hy = b$ is consistent, then $y = H^T b$ is the solution with the minimum 2-norm, where $H^T$ is the pseudo-inverse of $H$.

**Lemma 7.** Suppose that Assumption 3(A2) holds. Then, for any $x \in \mathbb{R}^n$, the following statements are equivalent.

1. There exist $\lambda_1 \in \mathbb{R}^s, \lambda_2 \in \mathbb{R}^r$ such that $G(x) = A^T \lambda_1 + B^T \lambda_2$.

2. Consider
\[
\left\{-A^{-1}_L B^T \left(\left(\begin{array}{c} A^T \end{array}\right) - I \right) B^T \right\} \left[\begin{array}{c} A^T \lambda^*_1 - I \end{array}\right] + A^T - I \right) B^T \right\} \}
\]

where $A_L^{-1} = (AA^T)^{-1} A$.

**Proof.** The proof follows that of Lemma 2.1 in [4], and for completeness, we include it.

Set
\[
X_1 := \left\{ x \in \mathbb{R}^n \mid G(x) = A^T \lambda_1 + B^T \lambda_2 \right\}
\]
for some $\lambda_1 \in \mathbb{R}^s, \lambda_2 \in \mathbb{R}^r$.

\[
X_2 := \left\{ x \in \mathbb{R}^n \mid \left\{-A^{-1}_L B^T \left(\left(\begin{array}{c} A^T \end{array}\right) - I \right) B^T \right\} \right\} \}
\]

Now, we show that these two sets are equal.

First, for any $x \in X_1$, there exist $\lambda_1 \in \mathbb{R}^s, \lambda_2 \in \mathbb{R}^r$ such that
\[
G(x) = A^T \lambda_1 + B^T \lambda_2.
\]

Premultiplying (8) by $A_L^{-1}$ gives
\[
A_L^{-1} G(x) = A_L^{-1} A^T \lambda_1 + A_L^{-1} B^T \lambda_2.
\]

Combining this with (8) yields that
\[
G(x) = A^T \left(\begin{array}{c} A_L^{-1} G(x) - A_L^{-1} B^T \lambda_2 \end{array}\right) + B^T \lambda_2,
\]
\[
= A^T A_L^{-1} G(x) - \left[\begin{array}{c} A^T A_L^{-1} B^T - B^T \end{array}\right] \lambda_2;
\]
that is,
\[
\left[A^TA_L^{-1}B^T - B^T \right] \lambda_2 = \left[A^TA_L^{-1} - I \right] G(x).
\] (11)

Recalling Lemma 6, we further have
\[
\lambda_2 = \left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \left[A^TA_L^{-1} - I \right] G(x).
\] (12)

Combining this with (9) yields that
\[
\lambda_1 = \left\{-A_L^{-1}B^T\left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \left[A^TA_L^{-1} - I \right] + A_L^{-1} \right\}
\times G(x).
\] (13)

Using (8), (12), and (13), we have
\[
\left\{A^T \left\{-A_L^{-1}B^T\left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \left[A^TA_L^{-1} - I \right] + A_L^{-1} \right\}
\times G(x) \right. \\
+ \left. B^T\left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \left[A^TA_L^{-1} - I \right] \right\} G(x) = 0.
\] (14)

From the fact that \( \lambda_1 \geq 0 \), by (13), one has
\[
\left\{-A_L^{-1}B^T\left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \left[A^TA_L^{-1} - I \right] + A_L^{-1} \right\} G(x)
\geq 0.
\] (15)

Combining this with (14) leads to that \( x \in X_2 \). This shows that \( X_1 \subseteq X_2 \).

Second, for any \( x \in X_2 \), let
\[
\left\{A^T \left\{-A_L^{-1}B^T\left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \left[A^TA_L^{-1} - I \right] + A_L^{-1} \right\}
\times G(x) \right. \\
+ \left. B^T\left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \left[A^TA_L^{-1} - I \right] \right\} G(x)
\] (16)

Then, \( \lambda_1 \in R^t \), \( \lambda_2 \in R^t \). From (14), one has
\[
G(x) = A^T \left\{-A_L^{-1}B^T\left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \left[A^TA_L^{-1} - I \right] + A_L^{-1} \right\}
\times G(x)
\] (17)
\[
+ B^T\left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \left[A^TA_L^{-1} - I \right] \right\} G(x)
\] (18)
\[
= A^T \lambda_1 + B^T \lambda_2;
\]

Combining this conclusion with Theorem 5, we can establish the following equivalent formulation of the GNCP:
\[
AF(x) \geq 0, \\
BF(x) = 0, \\
(F(x))^\top G(x) = 0, \\
UG(x) \geq 0, \\
VG(x) = 0,
\] (19)

where
\[
U = \left\{-A_L^{-1}B^T\left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \left[A^TA_L^{-1} - I \right] + A_L^{-1} \right\},
V = \left\{A^T \left\{-A_L^{-1}B^T\left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \\
\times \left[A^TA_L^{-1} - I \right] + A_L^{-1} \right\}
\right. \\
+ \left. B^T\left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \left[A^TA_L^{-1} - I \right] \right\}.
\] (20)

For the ease of description, we denote \( \mu = F(x), \nu = G(x) \).

Thus, system (18) can be written as
\[
A\mu \geq 0, \\
B\mu = 0, \\
\mu^\top \nu = 0, \\
U\nu \geq 0, \\
V\nu = 0.
\] (21)

For system (20), one has
\[
\mu^\top \nu = \mu^\top \left\{A^T \left\{-A_L^{-1}B^T\left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \\
\times \left[A^TA_L^{-1} - I \right] + A_L^{-1} \right\}
\right. \\
+ \left. B^T\left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \left[A^TA_L^{-1} - I \right] \right\} \nu
\] (22)
\[
\left. + B^\top \left[\left(A^TA_L^{-1} - I \right) B^T \right]^+ \left[A^TA_L^{-1} - I \right] \right\} \nu
\] (23)
\[
= [A\mu]^\top \left\{U\nu \right\},
\]
where the first equality follows from the last equality in (20), and the last equality uses the second equality in (20). Thus, system (20) can be further written as
\[
A\mu \geq 0, \\
B\mu = 0, \\
(A\mu)^\top (U\nu) = 0, \\
U\nu \geq 0, \\
V\nu = 0.
\] (24)

that is, \( x \in X_1 \). Hence, \( X_2 \subseteq X_1 \), and the desired result follows.
Furthermore, for any \((\mu, \nu) \in \mathbb{R}^m \times \mathbb{R}^m\) with \(A\mu \geq 0, U\nu \geq 0\), it holds from (21) that
\[
\mu^T \nu \geq 0. \tag{23}
\]
Now, consider the following optimization problem:
\[
\begin{align*}
\min_{\omega} & \quad f(\omega) = [(I,0)\omega] \quad [(0,I)\omega] \\
\text{s.t.} & \quad \omega \in \Omega,
\end{align*}
\]
where \(\omega = (\mu, \nu), \Omega = \{ \omega \in \mathbb{R}^{2m} \mid A(I,0)\omega \geq 0, B(I,0)\omega = 0, U(I,0)\omega \geq 0, V(I,0)\omega = 0 \} \). Denote the solution set of (24) by \(\Omega^*\).

**Lemma 8.** Under Assumption 3(A1), \(f(\omega)\) is a convex function.

**Proof.** For any \(\omega_1, \omega_2 \in \mathbb{R}^{2m}, \tau \in [0,1]\), we have
\[
\begin{align*}
f(\tau \omega_1 + (1-\tau) \omega_2) - \tau f(\omega_1) - (1-\tau) f(\omega_2) &= [(I,0)(\tau \omega_1 + (1-\tau) \omega_2)]^T \\
	imes [(0,I)(\tau \omega_1 + (1-\tau) \omega_2)] - \tau [(I,0)\omega_1]^T [(0,I)\omega_1] \\
&\quad - \tau [(I,0)\omega_1]^T [(0,I)\omega_1] - (1-\tau) [(I,0)\omega_2]^T [(0,I)\omega_2] \\
&\quad (25)
\end{align*}
\]
with \(\theta_{\text{opt}}\) being the optimal value of \(\theta\) on \(S\). There exists a scalar \(c_\gamma > 0\) such that
\[
\text{dist}(x,S) \leq c_\gamma \max \left\{ \text{dist}(x,P), \left[ \theta(x) - \theta_{\text{opt}} \right]_+ \right\}, \quad \forall x \in \mathbb{R}^n. \tag{26}
\]

Before proceeding, we present the following definition introduced in [15].

**Definition 12.** The mapping \(G : \mathbb{R}^n \to \mathbb{R}^m\) is said to be strongly nonexpanding with a constant \(\alpha > 0\) if \(\|G(x) - G(y)\| \geq \alpha \|x - y\|\).

By Lemma 8, \(f(\omega)\) is a convex function and the feasible set \(\Omega\) is a polyhedral. Combining this with Lemmas 10 and 11, we immediately obtain the following conclusion.

**Theorem 13.** Suppose that \(F\) is \(\gamma\)-strongly monotone with positive constants \(c_\gamma, \gamma\), respectively, and \(G\) is strongly nonexpanding with constant \(\alpha > 0\). Then, there exists constant \(\rho_1 > 0\) such that
\[
\text{dist}(x,X^*) \leq \rho_1 \left\{ \|AF(x)\| + \|BF(x)\| \\
+ \|UG(x)\| + \|VG(x)\| + \left[ F(x)^T G(x) \right]_+ \right\}^{\frac{1}{\gamma}} \left( \frac{1}{2} \right)^{2/(1+\gamma)}, \quad \forall x \in \mathbb{R}^n. \tag{29}
\]
Proof. For any \( x \in \mathbb{R}^n \), let \( \omega = (\mu, \nu) = (F(x), G(x)) \in \mathbb{R}^{2m} \). Then, there exists \( \omega^* = (\mu^*, \nu^*) = (F(x^*), G(x^*)) \in \Omega^* \) such that dist(\( \omega, \Omega^* \)) = \( \|\omega - \omega^*\| \). A direct computation yields that

\[
\operatorname{dist}^{1+\gamma}(x, x^*) \leq \left\| x - x^* \right\|^{1+\gamma}
\]

\[
\leq \frac{1}{\alpha^{1+\gamma}} \left\| G(x) - G(x^*) \right\|^{1+\gamma}
\]

\[
\leq \frac{1}{c_1 \alpha^{1+\gamma}} \left\| (F(x) - F(x^*))^\top (G(x) - G(x^*)) \right\|
\]

\[
\leq \frac{1}{c_1 \alpha^{1+\gamma}} \left\| F(x) - F(x^*) \right\| \left\| G(x) - G(x^*) \right\|
\]

\[
\leq \frac{1}{2c_1 \alpha^{1+\gamma}} \left\{ \left\| F(x) - F(x^*) \right\|^2 + \left\| G(x) - G(x^*) \right\|^2 \right\}
\]

\[
= \frac{1}{2c_1 \alpha^{1+\gamma}} \left\| \omega - \omega^* \right\|^2
\]

\[
= \frac{1}{2c_1 \alpha^{1+\gamma}} \operatorname{dist}^2(\omega, \Omega^*)
\]

\[
\leq \frac{1}{2c_1 \alpha^{1+\gamma}} \left\| \omega - \omega^* \right\|^2
\]

\[
\times \max \left\{ \operatorname{dist}(\omega, \Omega), \left\| f(\omega) \right\|, \left\| f(\omega) \right\|^{1/2} \right\}
\]

\[
\leq \frac{1}{2c_1 \alpha^{1+\gamma}} \left\| \omega - \omega^* \right\|^2
\]

\[
\times \max \left\{ c_2, 1 \right\} \left\{ \left\| A\mu \right\| + \left\| B\nu \right\| + \left\| U(0, I) \omega \right\| + \left\| V(0, I) \omega \right\| \right\}
\]

\[
\leq \frac{1}{2c_1 \alpha^{1+\gamma}} \left\| \omega - \omega^* \right\|^2
\]

\[
\times \max \left\{ c_2, 1 \right\} \left\{ \left\| A\mu \right\| + \left\| B\nu \right\| + \left\| U\nu \right\| + \left\| V\nu \right\| + \left\| [\mu^\top \nu]^\top \right\|^{1/2} \right\}
\]

where the second inequality follows from Definition 12 with constant \( \alpha > 0 \), the third inequality follows from Definition 1(iii) with constants \( c_1 > 0 \), \( \gamma > 0 \), the fourth inequality follows from the Cauchy-Schwarz inequality, the fifth inequality follows from the fact that \( (1/2)(a^2 + b^2) \geq ab \), for all \( a, b \in \mathbb{R} \), the sixth inequality follows from Lemma 1 with constant \( c_1 > 0 \) and Lemma 9, and the seventh inequality follows from Lemma 10 with constant \( c_2 > 0 \). By (30) and letting \( \rho_1 = \{(1/2c_1 \alpha^{1+\gamma})c_2^2 \max\{c_2, 1\}^2\}^{1/(1+\gamma)} \), then the desired result follows.

Remark 14. It is clear that if \( F \) is \( \gamma \)-strongly \( G \)-monotone and \( G \) is strongly nonexpanding, then

\[
\langle F(x) - F(y), G(x) - G(y) \rangle \geq c_1 \|G(x) - G(y)\|^{1+\gamma}
\]

\[
\geq c_1 \alpha^{1+\gamma} \|x - y\|^{1+\gamma},
\]

\[
\forall x, y \in \mathbb{R}^n.
\]

Moreover, the conditions which both \( F \) and \( G \) are Hölder continuous (or both \( F \) and \( G \) are Lipschitz continuous) in Theorem 13 are removed. Thus, Theorem 13 is stronger than Theorem 2.5 in [5]. Furthermore, by Theorem 2.1 in [5], the GNCP can be reformulated as general variational inequalities problem, and the conditions in Theorem 13 are also weaker than those in Theorem 3.1 in [15], Theorem 3.1 in [11], Theorem 3.1 in [10], and Theorem 2 in [9], respectively.

On the other hand, the condition that \( F \) is \( \gamma \)-strongly \( G \)-monotone and \( G \) is strongly nonexpanding in Theorem 13 is extended compared with the condition that \( F \) is strongly monotone with respect to \( G \) (i.e., \( \gamma = 1 \)) in Theorems 3.4 and 3.6 in [15], and it is also extended than compared with the condition \( F \) is strongly monotone with respect to \( G \) (i.e., \( \gamma = 1 \)) in Theorem 3.1 in [11], and compared with the condition that \( F(x) = x, G(x) \) is strongly monotone (i.e., \( \gamma = 1 \)) in Theorem 3.1 in [10].

Using the following Definition 15 developed from the complementarity conditions in (22), we can further detect the error bound of the GNCP.

Definition 15. A solution \( x_0 \) of the GNCP is said to be non-degenerate if it satisfies

\[
AF(x_0) + UG(x_0) > 0.
\]

Lemma 16. Suppose that Assumptions 3(A1) and 3(A2) hold, and the GNCP has a nondegenerate solution, say \( x_0 \). Then,

\[
\Omega^* = \{ \omega \in \Omega \mid [(I, 0)\omega]^\top [(I, 0)\omega] = 0 \; \text{and} \; [(I, 0)\omega]^\top [(I, 0)\omega] = 0 \},
\]

\[
\Omega^* = [(I, 0)\omega]^\top [(I, 0)\omega] = 0,
\]

by Assumption 3(A1), for any \( \omega \in \Omega \), we have

\[
0 \leq (\mu - \mu_0)^\top (\nu - \nu_0)
\]

\[
= [(I, 0)\omega - (I, 0)\omega_0]^\top [(I, 0)\omega - (I, 0)\omega_0]
\]

\[
= [(I, 0)\omega]^\top [(I, 0)\omega] - [(I, 0)\omega_0]^\top [(I, 0)\omega_0]
\]

\[
- [(I, 0)\omega_0]^\top [(I, 0)\omega_0];
\]

that is,

\[
[(I, 0)\omega]^\top [(I, 0)\omega] + [(I, 0)\omega]^\top [(I, 0)\omega]
\]

\[
\leq [(I, 0)\omega]^\top [(I, 0)\omega].
\]
To prove the assertion, we only need to show that the solution set $\Omega^*$ is equal to the set
\[
W := \{ \omega \in \Omega \mid [(I, 0) \omega] + [(0, I) \omega_0] = 0 \}.
\]

For any $\tilde{\omega} \in \Omega^*$, combining Lemma 9 with (20) yields that
\[
[(I, 0) \tilde{\omega}]^T [(0, I) \tilde{\omega}] = 0.
\]

Letting $\omega = \tilde{\omega}$ in (36) yields that
\[
[(I, 0) \omega] + [(0, I) \tilde{\omega}^T [(I, 0) \omega_0] = 0.
\]

Since $\tilde{\omega}_0, \omega_0 \in \Omega$, using the similar technique to that of (21), we can obtain
\[
[(I, 0) \omega] + [(0, I) \omega] + [(I, 0) \omega_0] = 0.
\]

Hence, $\omega \in \Omega^*$. \hfill \Box

Based on Lemma 16, we obtain the following conclusion.

**Corollary 17.** Suppose that the hypotheses of Lemma 16 hold. Then,
\[
\Omega^* = \{ \omega \in \Omega \mid [(I, 0) \omega] + [(0, I) \omega_0] = 0 \}.
\]

**Theorem 18.** Suppose that the hypotheses of Theorem 13 hold, and the GNCP has a nondegenerate solution. Then, there exists constant $\rho_2 > 0$ such that
\[
\text{dist}(x, X^*) \leq \rho_2 \left\{ \| [A F(x)]_+ \| + \| B F(x) \| + \| [U G(x)]_+ \| \right. \]
\[
+ \| V G(x) \| + \left\| [F(x)^T G(x)]_+ \right\|^{2/(1+\gamma)}, \quad \forall x \in \mathbb{R}^n.
\]

**Proof.** For any $x \in \mathbb{R}^n$, let $\omega = (\mu, \nu) = (F(x), G(x)) \in \mathbb{R}^{2m}$. Then, there exists $\omega^* = (\mu^*, \nu^*) = (F(x^*), G(x^*)) \in \Omega^*$ such that $\text{dist}(\omega, \Omega^*) = \| \omega - \omega^* \|$. Letting $x_0$ be a nondegenerate solution of GNCP and letting $\omega_0 = (F(x_0), G(x_0)) \in \Omega^*$, then
\[
\text{dist}^{1+\gamma}(x, X^*) \leq \| x - x^* \|^{1+\gamma}
\]
\[
\leq \frac{1}{2c_1\alpha^{1+\gamma} \gamma 2} \sqrt{\text{dist}^{2}(\omega, \Omega^*)}
\]
\[
\leq \frac{1}{2c_1\alpha^{1+\gamma} 2\gamma} \sqrt{\text{dist}^{2}(\omega, \Omega^*)}
\]
\[
	imes \left\{ \left[ [A (I, 0) \omega]_0 + \| [U (0, I) \omega]_0 \| \right. \right.
\]
\[
+ \| B (I, 0) \omega \| + \| V (0, I) \omega \|
\]
\[
+ \left\| [((I, 0) \omega) + [(0, I) \omega_0] \right\|^{2}
\]
\[
\leq \frac{1}{2c_1\alpha^{1+\gamma} 2} \sqrt{\text{dist}^{2}(\omega, \Omega^*)}
\]
\[
	imes \left\{ \left[ [A (I, 0) \omega] + \| [U \gamma]_0 \| + \| B \mu \|
\right. \right.
\]
\[
+ \| V \gamma \| + \left\| [\mu^T \gamma]_0 \right\|^{2}
\]
\[
\right\},
\]

where the second equality uses the similar technique to that of (30), the third inequality follows from Corollary 17 and Lemma 10 with constant $c_4 > 0$, and the last inequality is based on (36). By (48) and letting $\rho_2 = \left(1/\alpha^{1+\gamma} 2\gamma\right)^{1/(1+\gamma)}$, the desired result follows. \hfill \Box

In the following, we give an error bound of the Hölderian type [14].

**Lemma 19.** For $i = 1, 2, \ldots, m$, let $g_i(x)$ be a convex quadratic function. If the set $S := \{ x \in \mathbb{R}^n \mid g_i(x) \leq 0,$
Abstract and Applied Analysis
g_2(x) \leq 0, \ldots, g_m(x) \leq 0 \) is nonempty, then there exist a positive integer \( d \leq n + 1 \) (called the degree of singularity of the inequality system) and a positive scalar \( c_5 \) such that
\[
\text{dist}(x, S) \leq c_5 \max \left\{ \|g(x)\|, \|g(x)\|^{1/2d} \right\}, \quad \forall x \in \mathbb{R}^n,
\]
(49)
where \( [g(x)]_+ = (|g_1(x)|, |g_2(x)|, \ldots, |g_m(x)|) \). Furthermore, if \( S \) contains an interior point, then \( d = 0 \).

Based on (18) and (21), the GNCP can also be written as
\[
\begin{align*}
AF(x) & \geq 0, \\
BF(x) & = 0, \\
(F(x))^T G(x) & \leq 0, \\
UG(x) & \geq 0, \\
VG(x) & = 0.
\end{align*}
\]
(50)
From Lemma 19, we can establish the following global error bound for GNCP.

**Theorem 20.** Suppose that the hypotheses of Theorem 13 hold, and there exists point \( \hat{x} \in \mathbb{R}^n \) such that
\[
F(\hat{x})^T G(\hat{x}) < 0.
\]
(51)
Then, there exists constant \( \rho_3 > 0 \) such that
\[
\text{dist}(x, X^*) \leq \rho_3 \left\{ \|AF(x)\| \|BF(x)\| + \|UG(x)\| + \|VG(x)\| + \|F(x)^T G(x)\|^{2/(1 + \gamma)} \right\}, \quad \forall x \in \mathbb{R}^n.
\]
(52)

**Proof.** Let \( S_1 := \{ \omega \in \mathbb{R}^{2m} \mid f(\omega) \leq 0 \} \), where \( f(\omega) = [(I, 0)\omega]^T [(0, I)\omega] \). By Lemma 8, we have \( f(\omega) \) is a convex quadratic function. Combining this with (51), using Lemma 19 with \( d = 0 \), this yields the following result
\[
\text{dist}(\omega, S_1) \leq c_6 \|f(\omega)\|_+, \quad \forall \omega \in \mathbb{R}^{2m},
\]
(53)
where \( c_6 \) is a positive constant.

Obviously, \( S_1 \) is a closed convex set. Thus, for any \( \omega \in \mathbb{R}^{2m} \), there exists a vector \( \omega^- \in S_1 \) such that
\[
\|\omega - \omega^-\| = \text{dist}(\omega, S_1).
\]
(54)
For convenience, we also let
\[
\Psi(\omega) = (-A(I, 0)\omega, -B(I, 0)\omega, -U(0, I)\omega, \\
-V(0, I)\omega, B(I, 0)\omega, V(0, I)\omega),
\]
(55)
From (50), we have \( \Omega^* = \Omega \cap S_1 \), where \( \Omega \) is defined in (24), so for any \( \omega \in S_1 \), combining Lemma 10, one has
\[
\text{dist}(\omega, \Omega^*) \leq c_7 \left\{ \|(-A(I, 0)\omega, -B(I, 0)\omega, -U(0, I)\omega, \\
-V(0, I)\omega, B(I, 0)\omega, V(0, I)\omega)\| + \|F(\omega)\| \right\}^{1/2}, \quad \forall \omega \in \mathbb{R}^{2m}.
\]
(56)
\[\begin{align*}
&\leq (\|A(I,0)\| + 2\|B(I,0)\| + \|U(0,I)\| + 2\|V(0,I)\|) \\
&\quad \times \|\omega - \bar{a}\| \\
&= (\|A(I,0)\| + 2\|B(I,0)\| + \|U(0,I)\| + 2\|V(0,I)\|) \\
&\quad \times \text{dist}(\omega, S_1),
\end{align*}\]

where the second equality follows from the fact that
\[\min\{a, b\} = a - P_{R_+} (a - b), \quad \forall a, b \in R,\]

and the first inequality is by nonexpanding property of projection operator. Thus,
\[
\Psi(\omega) \leq \|\Psi(\omega)\| \\
\quad + (\|A(I,0)\| + 2\|B(I,0)\| + \|U(0,I)\| + 2\|V(0,I)\|) \times \text{dist}(\omega, S_1).
\]

Combining (56) with (59), for any \(\omega \in R^{2m}\), we have
\[
dist(\omega, \Omega^*) \leq \text{dist}(\omega, S_1) + \|\bar{a}, \Omega^*\| \\
\leq \text{dist}(\omega, S_1) + \sigma \|\Psi(\omega)\| \\
\quad + \sigma (\|\Psi(\omega)\| \\
\quad + (\|A(I,0)\| + 2\|B(I,0)\| + \|U(0,I)\| + 2\|V(0,I)\|) \times \text{dist}(\omega, S_1)) \\
\leq \sigma \|\Psi(\omega)\| \\
\quad + [\sigma (\|A(I,0)\| + 2\|B(I,0)\| \\
\quad + \|U(0,I)\| + 2\|V(0,I)\|)] + 1) \\
\quad \times \text{dist}(\omega, S_1) \\
\leq \sigma \|\Psi(\omega)\| \\
\quad + [\sigma (\|A(I,0)\| + 2\|B(I,0)\| \\
\quad + \|U(0,I)\| + 2\|V(0,I)\|)] + 1) \times \|f(\omega)\| \\
\leq \eta \left(\|\Psi(\omega)\| + \left\|f(\omega)\right\|\right) \\
\leq \eta \left(\|\Psi(\omega)\| + \left\|f(\omega)\right\|\right) \\
\leq \eta \left(\|B(I,0)\omega\| + \|V(0,I)\omega\| + \left\|f(\omega)\right\|\right) \\
\leq \eta \left(\sqrt{n} \|B(I,0)\omega\| + \sqrt{n} \|V(0,I)\omega\| \\
\quad + \sqrt{m} \|V(0,I)\omega\| + \sqrt{m} \|V(0,I)\omega\| \\
\quad + \left\|f(\omega)\right\|\right)
\]

where the second inequality follows from (56) with constant \(\sigma = c_1 \sqrt{2} + 2\|I\| + 2m\), the third inequality uses (59), the fifth inequality follows from (53), the sixth inequality follows from the fact that
\[
\eta = \max \left\{\sigma, \left(\|A(I,0)\| + 2\|B(I,0)\| + \|U(0,I)\| \\
\quad + 2\|V(0,I)\| + 1\right) c_6\right\},
\]

the seventh and ninth inequalities follow from the fact that
\[
\|x\| \leq \|x\|_1 \leq \sqrt{n} \|x\|_1, \quad \forall x \in R^n,
\]

and the last inequality follows by letting \(c_8 = \eta \max\{\sqrt{n}, \sqrt{m}, \sqrt{m}, 1\}\).

For any \(x \in R^n\), letting \(\omega := (\mu, \nu) = (F(x), G(x)) \in R^{2m}\), then there exists \(\omega^* = (\mu^*, \nu^*) = (F(x^*), G(x^*)) \in \Omega^*\) such that \(\text{dist}(\omega, \Omega^*) = \|\omega - \omega^*\|\), and a direct computation yields that
\[
\text{dist}^{1+\gamma} (x, X^*) \leq \left\|x - x^*\right\|^{1+\gamma} \\
\leq \frac{1}{2c_1 \alpha^{1+\gamma}} \text{dist}^{2} (\omega, \Omega^*) \\
\leq \frac{1}{2c_1 \alpha^{1+\gamma}} c_8^2 \\
\times \left\{\left[\|A(I,0)\omega\| + \|U(0,I)\omega\| \\
\quad + \|B(I,0)\omega\| + \|V(0,I)\omega\|\right] \right\}^2 \\
= \frac{1}{2c_1 \alpha^{1+\gamma}} c_8^2 \left\{\left[A\mu\right] \| + \left[U\nu\| + \|B\mu\| \\
\quad + \|V\nu\| + \left[\mu\nu\|\right]^2\right\}^2,
\]

where the deduction of the second equality uses the similar technique to that of (30), and the third inequality is by (60). By (63) and letting \(\rho_3 = \left\{(1/2c_1 \alpha^{1+\gamma})c_8^2\right\}^{1/(1+\gamma)}\), then the desired result follows.

\[\square\]

Remark 21. When \(F\) is strongly monotone with respect to \(G\), that is, \(\gamma = 1\), without the requirement of nondegenerate solution, the square root term in the error bound estimation is removed as stated in Theorem 20. Hence, the error estimation becomes more practical than that in Theorem 4.1 in [4].
3. Global Error Bound for the GLCP

In this section, we consider the linear case of the GCP such that mappings \( F \) and \( G \) are both linear; that is, \( F(x) = Mx + p \), \( G(x) = Nx + q \) with \( M, N \in \mathbb{R}^{m \times n}, p, q \in \mathbb{R}^m \):

\[
\begin{align*}
\min & \quad H(x) = (Mx + p)^\top (Nx + q) \\
\text{s.t.} & \quad x \in X,
\end{align*}
\]

where

\[
X = \left\{ x \in \mathbb{R}^n \mid A(Mx + p) \geq 0, U(Nx + q) \geq 0, B(Mx + p) = 0, V(Nx + q) = 0 \right\}.
\]

For problem (64), combining (18) with (23) and using a similar discussion in Lemmas 8 and 9, we also have the following conclusion.

Lemma 22. Under Assumption 3(A1), \( H(x) \) is a convex function.

Lemma 23. \( x^* \in \mathbb{R}^n \) is a solution of the GLCP if and only if \( x^* \) is global optimal solution with the objective vanishing of (64).

Based on (64), using the argument similar to that of Theorem 13, we can obtain the following conclusion.

Theorem 24. Under Assumptions 3(A1) and 3(A2), and that mappings \( F \) and \( G \) are both linear, there exist constant \( \rho_4 > 0 \) such that

\[
\text{dist} (x, X^*) \leq \rho_4 \left\{ \| [A(F(x)) + B(F(x))] \| + \| [U(G(x)) + V(G(x))] \| + \right.
\]

where the first inequality follows from Lemma II with constant \( c_2 > 0 \) and Lemma 23, and the second inequality uses Lemma 10 with constant \( c_{10} > 0 \). By (67) and letting \( \rho_5 = c_9 \max \{ c_{10}, 1 \} \), the desired result follows.

Remark 25. Obviously, Assumption 3(A2) in Theorem 24 is weaker than Assumption (A2) in Theorem 4.1 in [4], Assumption 3(A1) coincides with Assumption (A1) in [4]. In addition, Theorem 24 is sharper than Theorem 4.1 in [4].

The following result further estimates the error bound for the GLCP.

Theorem 26. Suppose that the hypotheses of Theorem 24 hold, and the GLCP has a nondegenerate solution. Then, there exists constant \( \rho_5 > 0 \) such that

\[
\text{dist} (x, X^*) \leq \rho_5 \left\{ \| [A(F(x)) + B(F(x)) + [U(G(x)) + V(G(x))] \| + \right.
\]

where \( x_0 \) is a nondegenerate solution of GLCP, and \( X \) is defined in (64). For any \( x \in \mathbb{R}^n \), a direct computation yields

\[
\text{dist} (x, X^*) \leq c_{11} \left\{ \| [A(Mx + p)] \| + \| [U(Nx + q)] \| + \right.
\]

where the first inequality follows from Lemma II with constant \( c_2 > 0 \) and Lemma 23, and the second inequality uses (36). Letting \( \rho_5 = c_{11} \), the desired result follows.

Remark 27. The condition in Theorem 26 is weaker than that in Theorem 4.2 in [4].
Theorem 28. Suppose that the hypotheses of Theorem 24 hold, and there exists point $\bar{x} \in R^n$ such that (51) holds. Then there exists constant $\rho_0 > 0$ such that

$$\text{dist} (x, X^*) \leq \rho_0 \left[ \| AF(x) \| + \| BF(x) \| + \| UG(x) \| + \| VG(x) \| + \| F(x)^T G(x) \| \right],$$

\( \forall x \in R^n. \) (71)

Proof. Let $S_2 := \{ x \in R^n \mid H(x) \leq 0 \}$, where $H(x) = (Mx + p)^T (Nx + q)$. By Lemma 22, $H(x)$ is a convex quadratic function, and $S_2$ is a closed convex set. For any $x \in R^n$, there exists a vector $\bar{x} \in S_2$ such that

$$\| x - \bar{x} \| = \text{dist} (x, S_2).$$

(72)

Combining (51) and applying Lemma 19 yield the following result:

$$\text{dist} (x, S_2) \leq c_{12} \left[ \| H(x) \| \right], \quad \forall x \in R^n,$n

(73)

where $c_{12}$ is a positive constant. For convenience, we let

$$\phi (x) = \langle -AF(x), BF(x), -UG(x), \rangle$$

$$-VG(x), BF(x), VG(x) \rangle.$$

From (50), we have $X^* = X \cap S_2$, where $X$ is defined in (64). So for any $x \in S_2$, combining Lemma 10 and using the similar technique to that of (56), one has

$$\text{dist} (x, X^*) \leq c_{13} \left[ \| AF(x) \| + \| UG(x) \| + \| BF(x) \| + \| VG(x) \| \right]$$

$$\leq c_{13} \sqrt{2s + 2t + 2m} \| \phi (x) \|,$n

(75)

where $c_{13}$ is a positive constant.

Using the fact that

$$\min \{ a, b \} = a - P_{R} (a - b), \quad \forall a, b \in R,$n

(67)

and using the similar technique to that of (57), one has

$$\| \phi (x) - \phi (\bar{x}) \|$$

$$= \| AF(x), BF(x), UG(x), VG(x), BF(x), VG(x) \| - \| AF(\bar{x}), BF(\bar{x}), UG(\bar{x}), \rangle$$

$$- \langle AF(\bar{x}), BF(\bar{x}), UG(\bar{x}), -VG(\bar{x}), BF(\bar{x}), VG(\bar{x}) \rangle \|$$

$$\leq \| AF(x) - AF(\bar{x}) \| + 2 \| BF(x) - BF(\bar{x}) \|$$

$$+ \| UG(x) - UG(\bar{x}) \| + 2 \| VG(x) - VG(\bar{x}) \|$$

$$\leq (\| AM \| + 2 \| BM \| + \| UN \| + 2 \| VN \|) \| x - \bar{x} \|$$

$$= (\| AM \| + 2 \| BM \| + \| UN \|$$

$$+ 2 \| VN \|) \| x - \bar{x} \|,$n

(77)

where the second inequality is by nonexpanding property of projection operator. Thus,

$$\| \phi (x) \| \leq \| \phi (\bar{x}) \| + (\| AM \| + 2 \| BM \|$$

$$+ \| UN \| + 2 \| VN \|) \| x - \bar{x} \|.$n

(78)

Combining (75) with (78), we know that for any $x \in R^n$, it holds that

$$\text{dist} (x, X^*)$$

$$\leq \text{dist} (x, S_2) + \text{dist} (x, S_2)$$

$$\leq \text{dist} (x, S_2) + \sigma_1 \| \phi (\bar{x}) \|$$

$$\leq \text{dist} (x, S_2) + \sigma_1 (\| AM \| + 2 \| BM \|$$

$$+ \| UN \| + 2 \| VN \|) \| x - \bar{x} \|$$

$$\leq \sigma_1 \| \phi (x) \|$$

$$\leq [\sigma_1 (\| AM \| + 2 \| BM \|$$

$$+ \| UN \| + 2 \| VN \|) + 1] \| x - \bar{x} \|$$

$$\leq \sigma_1 (\| AF(x) \| + \| BF(x) \|$$

$$+ \| UG(x) \| + \| VG(x) \| + \| H(x) \|)$$

$$\leq \eta_1 (\| AF(x) \| + \| BF(x) \|$$

$$+ \| UG(x) \| + \| VG(x) \| + \| H(x) \|)$$

$$\leq \eta_1 (\| AF(x) \| + \| BF(x) \|$$

$$+ \| UG(x) \| + \| VG(x) \| + \| H(x) \|)$$

$$\leq \rho_0 (\| AF(x) \| + \| BF(x) \|$$

$$+ \| UG(x) \| + \| VG(x) \| + \| H(x) \|)$$

$$\leq \rho_0 (\| AF(x) \| + \| BF(x) \| + \| UG(x) \| + \| VG(x) \| + \| H(x) \|)$$

$$\leq \rho_0 (\| AF(x) \| + \| BF(x) \| + \| UG(x) \| + \| VG(x) \| + \| H(x) \|)$$

(79)

where the second inequality follows from (75) with constant $\sigma_1 = c_{13} \sqrt{2s + 2t + 2m}$, the third inequality follows from (78), the fifth inequality follows from (73), the sixth inequality follows by letting $\eta_1 = \max \{ \sigma_1, \| AM \| + 2 \| BM \| + \| UN \| + 2 \| VN \| + 1 \},$ and the seventh and ninth inequality follow from the fact that

$$\| x \| \leq \| x \| \leq \sqrt{n} \| x \|, \quad \forall x \in R^n.$$n

(80)

By (79) and letting $\rho_0 = \eta_1 \max \{ \sqrt{\delta}, \sqrt{t}, \sqrt{m}, 1 \}$, the desired result follows. \qed
Remark 29. In Theorem 28, without the requirement of nondegenerate solution, the square root term in the error bound estimation is removed. Hence, the error estimation becomes more practical than that in Theorem 4.1 in [4].

4. Comparison with Existing Error Bound

In the end of this paper, we will present an example to compare Theorem 13 and Theorem 2.5 in [5]. Furthermore, we will present two examples to show the conclusion in Theorem 2.5 can provide a global error bound for the GNCP, while the conclusion in Theorem 2.5 in [5] cannot do.

Example 30. When \( X = R^m \), (2) reduces to the generalized nonlinear complementarity problem of finding vector \( x^* \in R^m \) such that

\[
F(x^*) \geq 0, \quad G(x^*) \geq 0, \quad F(x^*)^T G(x^*) = 0. \tag{81}
\]

For (81), using Theorem 13 with \( y = 1 \), we have

\[
\text{dist}(x, X^*) \leq \tilde{p} \rho \varphi(x), \quad \forall x \in R^m, \tag{82}
\]

where \( \varphi(x) =: \|F(x)\|_1 + \|G(x)\|_1 + \|F(x)^T G(x)\|_1 + \|G(x)^T F(x)\|_1^{1/2} \).

Using Theorem 2.5 in [5] with \( y = 1, v_1 = v_2 = 1, \) and \( \beta = 1, \) we have that there exists constant \( \beta > 0 \) such that

\[
\text{dist}(x, X^*) \leq \tilde{p} \rho \varphi(x), \tag{83}
\]

where \( \rho(x) =: \|F(x)\|_1 + \|G(x)\|_1 \). In addition,

\[
\varphi(x) \leq \left\{ 2 \sqrt{m} + \max \{F(x), G(x)\} \right\} \left\{ r(x) + r(x)^{1/2} \right\}. \tag{84}
\]

In particular, when \( \|x\| \leq c_{14} \) with constant \( c_{14} > 0 \), then there exists positive constant \( c_{15} \) such that

\[
\varphi(x) \leq c_{15} \left\{ r(x) + r(x)^{1/2} \right\}. \tag{85}
\]

In fact, we have

\[
\varphi(x) \leq \|F(x)\|_1 + \|G(x)\|_1 + \|F(x)^T G(x)\|_1 + \|G(x)^T F(x)\|_1^{1/2}
\]

\[
\leq 2 \sqrt{m} \min \{F(x), G(x)\}
\]

\[
\leq 2 \sqrt{m} \sum_{i=1}^{m} \|F(x)_i\|_1 \|G(x)_i\|_1^{1/2}
\]

\[
\leq 2 \sqrt{m} \sum_{i=1}^{m} \|F(x)_i\|_1 \|G(x)_i\|_1^{1/2}
\]

\[
\leq 2 \sqrt{m} \sum_{i=1}^{m} \|F(x)_i\|_1 \|G(x)_i\|_1^{1/2}
\]

\[
\leq 2 \sqrt{m} \min \{F(x), G(x)\}
\]

\[
\leq 2 \sqrt{m} \sum_{i=1}^{m} \|F(x)_i\|_1 \|G(x)_i\|_1^{1/2}
\]

where the first inequality follows from the fact that \( \|x\| \leq \|x\|_1 \), for all \( x \in R^m \), the second inequality follows from the proof that the fourth inequality follows from the fact that \( a \leq \|a, b\| \), for all \( a, b \in R \), the third inequality follows from the fact that \( a + b \leq a + b \), for all \( a, b \in R \), the fourth inequality follows from the Cauchy-Schwarz inequality.

Example 31. For mappings \( F, G : R_+ \to R \) involved in problem (81), we set

\[
F(x) = (x + 1)^2, \quad G(x) = \sqrt{x}. \tag{87}
\]

It is easy to see that the solution set \( X^* = \{0\} \), and one has

\[
\langle F(x) - F(y), G(x) - G(y) \rangle = \frac{x + y + 2}{\sqrt{x} + \sqrt{y}}(x - y)^2 \tag{88}
\]

\[
\geq (x - y)^2,
\]

where the first inequality follows from the fact that \( x + y + 2 \geq \sqrt{x} + \sqrt{y} \).

In fact, we consider the following four cases.

Case 1 \((x \geq 1 \text{ and } y \geq 1)\). Then, \( x \geq \sqrt{x} \) and \( y \geq \sqrt{y} \), and the desired result follows.

Case 2 \((0 \leq x \leq 1 \text{ and } 0 \leq y \leq 1)\). Then, \( \sqrt{x} \leq 1 \) and \( \sqrt{y} \leq 1 \), and the desired result follows.

Case 3 \((0 \leq x \leq 1 \text{ and } y \geq 1)\). Then, \( \sqrt{x} \leq 1 \) and \( \sqrt{y} \leq y \), and the desired result follows.

Case 4 \((x \geq 1 \text{ and } 0 \leq y \leq 1)\). Then, \( \sqrt{x} \leq x \) and \( \sqrt{y} \leq 1 \), and the desired result follows.
For any \( x(\epsilon) := \epsilon, \epsilon \geq 0 \). By Theorem 13 with \( y = 1 \), we can obtain
\[
\|x(\epsilon) - 0\| = \frac{\epsilon}{(\epsilon + 1)^2 \epsilon + \sqrt{\epsilon + 1}} \rightarrow 0 \quad (89)
\]
as \( \epsilon \to +\infty \). Thus, Theorem 13 provides a global error bound for the GNCP. Using Theorem 2.5 in [5], for \( x(\epsilon) \), we have
\[
\frac{\|x(\epsilon) - 0\|}{\varphi(x(\epsilon))} = \frac{\epsilon}{\min \{(\epsilon + 1)^2, \sqrt{\epsilon}\}} = \frac{\epsilon}{\sqrt{\epsilon}} = \epsilon \rightarrow +\infty \quad (90)
\]
as \( \epsilon \to +\infty \). Thus, Theorem 2.5 in [5] fails in providing an error bound for this GNCP.

**Example 32.** For mappings \( F, G : \mathbb{R} \to \mathbb{R} \) involved in problem (81), we set
\[
F(x) = \frac{1}{3}x^3 + x, \quad G(x) = x. \quad (91)
\]

It is easy to see that the solution set \( X^* = \{0\} \). Without loss of generality, we let \( x > y \), and one has
\[
F(x) - F(y) \geq (x - y)^2, \quad (92)
\]
where the inequality follows from the fact that
\[
\left( \frac{1}{3}x^3 + x \right) - \left( \frac{1}{3}y^3 + y \right) - (x - y)^2
= (x - y)\left[ \frac{1}{3}x^2 + \frac{1}{3}y^2 + \frac{1}{3}xy + 1 + (x - y) \right] \geq 0. \quad (93)
\]
In fact, we consider the following four cases.

**Case 1** \( (x > y \geq 0) \). Then, \((1/3)x^2 + (1/3)y^2 + (1/3)xy + 1 + (x - y) \geq 0\), and the desired result follows.

**Case 2** \( (0 \geq x > y) \). Then, \((1/3)x^2 + (1/3)y^2 + (1/3)xy + 1 + (x - y) \geq 0\), and the desired result follows.

**Case 3** \( (x \geq 0, y < 0 \text{ and } x + y \geq 0) \). Then,
\[
\frac{1}{3}x^2 + \frac{1}{3}y^2 + \frac{1}{3}xy + 1 + (x - y)
= \frac{1}{3}x(x + y) + \frac{1}{3}y^2 + 1 + (x - y) \geq 0, \quad (94)
\]
and the desired result follows.

**Case 4** \( (x \geq 0, y < 0 \text{ and } x + y \leq 0) \). Then,
\[
\frac{1}{3}x^2 + \frac{1}{3}y^2 + \frac{1}{3}xy + 1 + (x - y)
= \frac{1}{3}x^2 + \frac{1}{3}y(x + y) + 1 + (x - y) \geq 0, \quad (95)
\]
and the desired result follows.

Thus, we obtain
\[
\left\langle F(x) - F(y), G(x) - G(y) \right\rangle \geq (x - y)^3. \quad (96)
\]
For any \( x(\epsilon) := \epsilon, \epsilon \geq 0 \). By Theorem 13 with \( y = 2 \), we can obtain
\[
\frac{\|x(\epsilon) - 0\|}{\varphi(x(\epsilon))} = \frac{\epsilon}{\left\{ \left[ (1/3)\epsilon^3 + \epsilon \right] \epsilon + \sqrt{\left[ (1/3)\epsilon^3 + \epsilon \right] \epsilon} \right\}^{2/3}} \rightarrow 0 \quad (97)
\]
as \( \epsilon \to +\infty \). Thus, Theorem 13 provides a global error bound for the GNCP.

On the other hand, using Theorem 2.5 in [5], for \( x(\epsilon) \), we have
\[
\frac{\|x(\epsilon) - 0\|}{r(x(\epsilon))} = \frac{\epsilon}{\min \{(1/3)\epsilon^3 + \epsilon, \epsilon\}} = \frac{\epsilon}{\epsilon^{\delta}} \rightarrow +\infty \quad (98)
\]
as \( \epsilon \to +\infty \), where \( \delta \) is a constant with \( 1/3 < \delta \leq 1/2 \). Thus, Theorem 2.5 in [5] fails in providing an error bound for this GNCP.

### 5. Conclusion

In this paper, we established some global error bounds on the generalized nonlinear complementarity problems over a polyhedral cone, which improves the result obtained for variational inequalities and the GNCP [4, 5, 9–11] by weakening the assumptions. Surely, under milder conditions, we may establish global error bounds for GNCP and use the error bounds estimation to establish quick convergence rate of the methods for the GNCP. This is a topic for future research.

### Acknowledgments

The authors wish to give their sincere thanks to the associated editor and two anonymous referees for their valuable suggestions and helpful comments which improve the presentation of the paper. This paper considers the locations of multiple facilities in the space \( \mathbb{R}^p \), with the aim of minimizing the sum of weighted distances between facilities and regional customers, where the proximity between a facility and a regional customer is evaluated by the closest distance. Due to the fact that facilities are usually allowed to be sited in certain restricted areas, some locational constraints are imposed to the facilities of our problem. In addition, since the symmetry of distances is sometimes violated in practical situations, the gauge is employed in this paper instead of the frequently used norms for measuring both the symmetric and asymmetric distances. In the spirit of the Cooper algorithm (Cooper, 1964), a new location-allocation heuristic algorithm is proposed to solve this problem. In the location phase, the single-source subproblem with regional demands is reformulated into an equivalent linear variational inequality (LVI), and then, a projection-contraction (PC) method is adopted to find the optimal locations of facilities, whereas in the allocation phase, the regional customers are allocated to facilities according to the nearest center reclassification (NCR). The convergence of the proposed algorithm is proved under mild assumptions. Some preliminary numerical results are reported to show the effectiveness of the new algorithm.

1. Introduction

Due to the large number of practical applications in various fields such as marketing, urban planning, supply chain management, and transportation, the continuous facility location problem has aroused the attention of many researchers ever since the pioneering work [1, 2]. For a comprehensive review on this topic, see, for example, [3, 4]. More specifically, the continuous facility location problem in a space is to seek the optimal locations for facilities serving customers (also called demand points), with certain objectives such as minimizing the sum of distances between facilities and customers.

The vast majority of literature treats the locations of facilities and customers as points in a space. Hence, the distances between facilities and customers are just the point-to-point distance without any ambiguity. In practical applications, however, regional demand arises frequently in such scenarios as uncertain demand, mobile demand, or cumbersome discrete situation whose number of demand points is extremely large. For such scenarios, many authors (e.g., [5–11]) promote that the regional customer, that is, the locations of customers are geometrically connected regions rather than points, should be considered. Therefore, in this paper, we consider the case of regional customer.

The question to be emphasized here, however, is how to measure the proximity from a regional customer to a facility. In the literature, different kinds of distances have been used to measure the required proximity. For example, the average distance evaluated by the proximity between the facility and some mean point in the interior of a regional customer (e.g., [10–13]) and the farthest distance measured by the proximity between the facility and the farthest point on the boundary of a regional customer (e.g., [8, 9, 14, 15]). Definitely, the regional customers are treated by the average fashion when the average distance is considered, while the farthest distance realizes the worst-off nature in the sense that the regional customers are represented by their respective farthest points. In some real-life applications, however, the best-off nature is
of importance in facility location; see, for example, [6, 16, 17].

To realize precisely the desired best-off nature, we need to consider the closest distance; that is, the proximity from a regional customer to a facility is evaluated by the closest distance to this facility. Thus, in this paper, we consider the closest distance to measure such a proximity. Note that the three kinds of distances have been well justified in [14, 15] and the reader can be referred to them for more details.

Focusing on the real-life applications with vast eyes, the regional customers and the closest distances are highly essential to be considered. An example is about the communication network where several central servers are required to be sited. The demand points on the network are partially connected forming groups, each containing a large number of demand points. The points in the same group are connected to one another, and thus, each group becomes a regional customer in the plane. The servers need to be connected to the closest points in each regional customer, and the rest of the regional customer will be connected to the servers through that connection. Hence, the regional customers and the closest distances need to be used in the locations of these central servers. For more applications, we refer to, for example, [6, 15, 16].

As a matter of fact, in the literature of facility location, the distance is usually measured by norms such as $l_p$-norms and block norms. References [3, 18] discuss the approximations about the weighted $l_p$-norms based on statistical evidence. References [19, 20] investigate the use of block norms to obtain good approximation of actual distances. As it is known, the symmetry property of the norm assures that the distance from one point to another is always equal to the distance back. Nevertheless, as one of the first in-depth studies of mathematical location problems, [21] highlights the fact that in numerous real situations the symmetry of the distance is violated, for example, transportation in rush-hour traffic, flight in the presence of wind, navigation in the presence of currents, transportation on an inclined terrain, and so forth. For about two decades after the work of [21], however, no further research on this topic seems to be published, and only in the recent twenty years have the asymmetric distance problems started to attract the researchers’ interest, for example, [22–28].

In this paper, we are interested in the locations of multiple facilities in the space $R^p$ with the aim of minimizing the sum of weighted distance between these facilities and regional customers, where the distance between a facility and a regional customer is evaluated by the closest distance. In addition, we formulate this problem in a quite general way with the aim of enhancing its practical applicability. First, we recognize that, usually, not all the points in the space $R^p$ are possible locations; that is, new facilities are often allowed to be sited within the confines of the restricted areas. Therefore, we introduce locational constraints so that both the unconstrained and constrained problems are taken into consideration in this paper. Second, since the distance in many practical situations is not necessarily symmetric, the 

### 2. Model Description

This paper focuses on finding locations in the space $\mathbb{R}^p$ for $m$ facilities, with the objective to minimize the sum of weighted closest distances between these facilities and $n$ regional customers. Note that the minsum single-source models with closest distance have been well justified in [6, 16] where the distances are particularly measured by $l_1$-norm and $l_2$-norm, respectively. In our multi-source model, however, the gauge is used to measure the distances between facilities and regional customers, and thus, both the symmetric distance (including the $l_1$-norm used in [16] and the $l_2$-norm used in [6]) and the asymmetric distance are considered.

Let $B$ be a compact convex set in $\mathbb{R}^p$, and let the interior of $B$ contain the origin; then, the gauge of $B$ is defined by

$$\gamma(x) = \inf \left\{ \lambda > 0 \mid \frac{x}{\lambda} \in B \right\}, \quad \forall x \in \mathbb{R}^p. \quad (1)$$

$B$ is called the unit ball of $\gamma(\cdot)$ due to

$$B = \{ x \in \mathbb{R}^p \mid \gamma(x) \leq 1 \}. \quad (2)$$

This way to define a gauge from a compact convex set was first introduced by Minkowski [29]. The gauge $\gamma(\cdot)$ satisfies the following properties:

1. $\gamma(x) \geq 0$ and $\gamma(x) = 0 \iff x = 0$;
2. $\gamma(tx) = t\gamma(x)$ for any $t \geq 0$;
3. $\gamma(x + y) \leq \gamma(x) + \gamma(y)$ for any $x$ and $y \in \mathbb{R}^p$.

It follows from (2) and (3) that any gauge $\gamma(x)$ is a convex function of $x$. The distance measuring function can be derived from a gauge by

$$D(x, y) = \gamma(y - x). \quad (3)$$

The rest of this paper is organized as follows. Section 2 states the formulation of our problem, which is shown to be nonconvex and NP-hard. The spirit of the well-known location-allocation heuristic algorithm, which consists of a location phase and an allocation phase in each iteration, is also discussed in this section. In Section 3, the sub-problems arising in location phase and allocation phase are solved. More specifically, for the subproblem arising in allocation phase, the regional customers are allocated to facilities according to the nearest reclassification (NCR) heuristic, whereas for the single-source subproblem arising in location phase, the relationship between the subproblem and a monotone linear variational inequality (LVI) is firstly built, and then, a projection-contraction (PC) method is adopted to find the optimal location of the facility. A new location-allocation heuristic algorithm is proposed in Section 4 for solving our targeted problem, and its convergence is proved in Section 5. Preliminary numerical results are reported in Section 6 to verify the efficiency of the proposed algorithm. Finally, some conclusions are drawn in Section 7.
When $B$ is symmetric around the origin, according to the definition of (1), we have
\[ y(-x) = y(x), \quad \forall x \in \mathbb{R}^p. \tag{4} \]

Combining (3) and (4), it follows that
\[ D(x, y) = D(y, x), \tag{5} \]

which means that the distance measured by $y()$ is symmetric. On the contrary, when $B$ is not symmetric around the origin, (4) does not hold any more, and thus, the distance measured by the gauge $y()$ is asymmetric. Thus, when different compact convex sets are used as unit balls, different gauges (symmetric or asymmetric) can be generated and employed to measure distances in location problems, which depends on the requirements of practical applications.

Let $\Lambda = \{ A_j \subset \mathbb{R}^p \mid j = 1, \ldots, n \}$ denote the set of regional customers, and let $x_i (i = 1, \ldots, m)$ be the location of the $i$th facility. Each regional customer $A_j$ is simply assumed to be closed and convex. We denote the closest point in $A_j$ to the facility $x_i$ by
\[
a_j(x_i) := \arg\min\{D(q, x_i) \mid q \in A_j\}, \tag{6}\]

Then, the closest distance between the facility $x_i$ and the regional customer $A_j$, denoted by $d_j(x_i)$, can be represented by
\[
d_j(x_i) := \min_{q \in A_j} D(q, x_i) = y(x_i - a_j(x_i)). \tag{7}\]

When the gauge is used to measure distances, we have the following proposition for $a_j(x)$ and $d_j(x)$ which is similar to that in [16].

**Proposition 1.** Let $x$ be the location of a facility; then, the closest point $a_j(x)$ in (6) is well defined, and the closest distance $d_j(x)$ in (7) is a convex function of $x$.

**Proof.** Since $A_j$ is a convex set and $y()$ is a convex function, (6) is a convex problem, and thus, $a_j(x)$ is well defined.

Now, we prove that $d_j(x)$ is a convex function of $x$ as follows. Let $x$ and $y$ be two points in $\mathbb{R}^p$ and $\lambda \in [0, 1]$; then, due to $a_j(x)$ and $a_j(y)$ in $A_j$ and the convexity of $A_j$, it follows that $\lambda a_j(x) + (1 - \lambda) a_j(y) \in A_j$, and thus, we have
\[
d_j(\lambda x + (1 - \lambda) y) = \min_{q \in A_j} D(q, \lambda x + (1 - \lambda) y) \leq D(\lambda a_j(x) + (1 - \lambda) a_j(y), \lambda x + (1 - \lambda) y) \]

Therefore, $d_j(x)$ is convex with respect to $x$, and the proof is complete.

Based on the notations introduced above, now the constrained multi-source location problem (abbreviated as CMLP) we consider in this paper takes the following formulation:

\[
\text{CMLP:} \quad \min_{x, w} \sum_{j=1}^{n} \sum_{i=1}^{m} w_{ij} d_j(x_i) = \sum_{j=1}^{n} \sum_{i=1}^{m} w_{ij} y(x_i - a_j(x_i)) \\
\text{s.t.} \quad \sum_{j=1}^{m} w_{ij} = s_j, \quad j = 1, 2, \ldots, n, \\
x_i \in \Pi_i, \quad i = 1, 2, \ldots, m, \tag{9}\]

where $s_j \geq 0$ is the given demand required by the $j$th customer, $X = (x_1^T, \ldots, x_n^T)^T$ is the variable of the locations of facilities to be determined, $W = (w_{ij})_{m \times n}$ is the undetermined variable of $w_{ij}$, which denotes the unknown allocation from the $i$th facility to the $j$th customer, and $\Pi_i$ is the locational constraint for the $i$th facility which is assumed to be a convex and closed set in $\mathbb{R}^p$.

More explanations are required for our model (9). First, the locational constraint $\Pi_i$ in (9) can also be chosen as $\mathbb{R}^p$, and if all $\Pi_i (i = 1, \ldots, m)$ are $\mathbb{R}^p$, the CMLP (9) is a unconstrained problem, and thus, both the constrained and unconstrained problems are considered in our model. Second, mark that the minsum models analyzed in [6, 16] are two special cases of CMLP (9), where $m = 1$, $\Pi_i = \mathbb{R}^p$, and $y(x)$ is particularly $l_1$-norm in [16] and Euclidean norm in [6].

It is noted that, with the presupposition that each facility is capable of providing sufficient services for the targeted customers, each customer is ultimately served only by the nearest facility in order to minimize the total sum of weighted distances. Therefore, the mathematical model CMLP also has the following form:

\[
\text{CMLP}: \quad \min_{x \in \Pi} C(X) = \sum_{j=1}^{n} s_j \min_{1 \leq i \leq m} d_j(x_i) = \sum_{j=1}^{n} s_j \min_{1 \leq i \leq m} y(x_i - a_j(x_i)), \tag{10}\]

where $\Pi$ is the cartesian product of locational constraints; that is, $\Pi = \Pi_1 \times \cdots \times \Pi_m$. 

When all \( A_j \) are points not regions and all \( \Pi_i \) are \( R^p \), CMLP (9) reduces to the well-known multi-source Weber problem (MWP) which has wide applications in operations research, marketing, urban planning, and so forth; see, for example, [3, 30, 31]. Recall the fact that the multi-source Weber problem is nonconvex [32] and NP-hard [33], and therefore, heuristics algorithms are extremely popular and highly appreciated for overcoming the difficulty caused by its nonconvexity and NP-hardness; see, for example, [3, 30, 34–37]. In particular, the classical location-allocation heuristic, also called the Cooper algorithm, has received much attention ever since it was presented originally by Cooper in [34] for MWP, whose attractive characteristic is that each iteration consists of a location phase and an allocation phase. Now, as a more general problem of MWP, CMLP is also nonconvex and NP-hard. Hence, in this paper, we are interested in applying the location-allocation heuristic to solve the CMLP (9). Accordingly, some location subproblems and allocation subproblems occur. To clarify it, let \( \mathcal{M} = \{1, 2, \ldots, m\}, \mathcal{A} = \{1, 2, \ldots, n\} \), and then \( \Lambda = \mathcal{A}_j : j \in \mathcal{M} \). At the \((k-1)^{th}\) iteration, let \( \Lambda^{k-1} = \{\Lambda_1^{k-1}, \Lambda_2^{k-1}, \ldots, \Lambda_m^{k-1}\} \) be the disjoint partition of \( \Lambda \) in the sense that \( \bigcup_{i=1}^{m} \Lambda_i^{k-1} = \Lambda \) and \( \Lambda_i^{k-1} \cap \Lambda_j^{k-1} = \emptyset \) (for \( i \neq j \)), and each \( \Lambda_i^{k-1} \) is the part of \( i = 1, \ldots, m \) in the partition is called one cluster. Then, at the \( k^{th} \) iteration, the location phase finds the candidates of locations of facilities (denoted by \( x_1^k, x_2^k, \ldots, x_m^k \)) by solving the following \( m \) constrained single-source location problems (CSLP) with the closest distance under gauge for each cluster \( \Lambda_i^{k-1} \), \( i = 1, \ldots, m \):

\[
\text{CSLP:} \quad x_i^k = \arg \min_{x \in \Pi_i} \left\{ C_i^k (x) := \sum_{j \in \mathcal{A}_j, j \in \Lambda_i^{k-1}} s_j \gamma(x - a_j (x)) \right\} = \sum_{j \in \mathcal{A}_j, j \in \Lambda_i^{k-1}} s_j \min_{q \in \Lambda_i^{k-1}} \gamma(x - q_j), \quad i = 1, \ldots, m.
\]

After the location phase, the allocation phase then revises the current partition of \( \Lambda \) to generate a new disjoint partition of \( \Lambda = \{\Lambda_1^k, \Lambda_2^k, \ldots, \Lambda_m^k\} \) by the following nearest center reclassification (NCR) heuristic (see [38]): for some customer \( A_j \in \Lambda_h^k \) \( \{(j \in \Pi_i, h \in \Pi_j)\} \) is the nearest point for \( A_j \) among all \( x_i^k \) computed by (11), then \( \Lambda_h^k = \Lambda_h^k \setminus \{A_j\} \) and \( \Lambda_j^k = \Lambda_j^k \cup \{A_j\} \). If \( x_i^k \) solved by (11) is the nearest facility for every regional customer in \( \Lambda_i^k \) for any \( i \in \{1, 2, \ldots, m\} \), then \( x_i^k \) \( i = 1, 2, \ldots, m \) are the desirable locations of facilities and stop. Otherwise, we set \( k = k + 1 \) and repeat the iterations.

3. The Subproblems in Location and Allocation Phases

In this section, we will discuss the subproblems arising in the location phase and allocation phase. The allocation phase will partition the customers to \( m \) clusters by the nearest center reclassification (NCR) heuristic, and the location phase will find the optimal location for each cluster by solving \( m \) CSLPs (II).

3.1. Nearest Center Reclassification for Allocation of Customers. The implementation of NCR heuristic to allocate regional customers can be executed by the following framework; see [38] for more details about this heuristic.

Algorithm 2 (the implementation of NCR). Given an initial partition \( \Lambda^0 = \{\Lambda_1^0, \Lambda_2^0, \ldots, \Lambda_m^0\} \); for \( k = 1, 2, \ldots \), do:

Step 1. Set \( t = 0 \) (\( t \) stores the number of reassignments);

Step 2. Compute the facility \( x_i^k \) of \( \Lambda_i^{k-1} \) by solving CSLP (II), for \( i = 1, 2, \ldots, m \);

Step 3. For \( j = 1, 2, \ldots, n \) do:

\[
d_{ij} := \gamma(x_i^k - a_j (x_i^k)) \quad \text{for} \quad i = 1, \ldots, m;
\]

if \( A_j \in \Lambda_h^k \) and \( d_{ij} = \min_{j \in \Phi, i \in \Pi} d_{ij} \), then \( \Lambda_h^k = \Lambda_h^k \setminus \{A_j\}, \Lambda_j^k = \Lambda_j^k \cup \{A_j\} \),

\( t = t + 1 \).

Step 4. If \( t = 0 \), then the iteration terminates with \( \{x_1^k, \ldots, x_m^k\} \) being the desirable locations for facilities and the customers in \( \Lambda_i^{k-1} \) being served by \( x_i^k \) \( i = 1, \ldots, m \).

3.2. The Variational Inequality Approach for CSLP (II). According to the spirit of location-allocation heuristic algorithm, our central task for the CMLP is to solve CSLP (II) in location phase by an efficient means. Recall that the CSLP is a generalized problem of the minisum models discussed in [6,16], where \( \Pi_i = R^p \) and the gauge \( \gamma(\cdot) \) are the particular \( l_1 \)-norm in [16] and \( l_2 \)-norm in [6]. For the model under \( l_1 \)-norm in [16], by taking advantage of the piecewise linearity of the objective function, this model can be reduced to a standard minisum problem which can be easily solved by obtaining a median point for each coordinate separately. For the minisum model under \( l_2 \)-norm in [6], an efficient Weiszfeld-type method is proposed, and the convergence of this method is analyzed. Similar to Weiszfeld procedure [2], one problem of the proposed method is that the singular case, that is, the current iterate happens to be within some location of regional customers, may occur during its implementation. Due to the use of the gradient of objective function in the iteration, this method will terminate unexpectedly once the singular case occurs. In order to tackle the undesirable singular case and make the Weiszfeld-type method computational effective, the authors suggest to ignore the gradient of \( \|x - a_j (x)\| \) if \( x \in A_j \) and then add an extra descent check and a boundary check to the iteration. As pointed out by Theorem 1 in [6], however, the sequence generated by the proposed Weiszfeld-type method is possible to be convergent to a nonoptimal point which is on the boundary of the regional customer.

In this section, a variational inequality approach is proposed to solve the general CSLP (II), where the locational constraints are imposed to the facility and the gauge is
used as distance measuring function. Note that the study of variational inequality has received much attention due to its various applications arising in engineering, operations research, economics, transportation, and so forth; see, for example, [39–45]. Specifically, the CSLP (II) considered in this paper is first reformulated into an equivalent linear variational inequality (LVI), and then, a projection-contraction (PC) method is adopted to solve the LVI. Consequently, a sequence will be generated by the variational inequality approach, which is shown to be convergent to the optimal solution of the problem.

Let \( \Lambda^k \) contain \( d \) customers, throughout this section, we ignore some superscripts and subscripts in (11) and consider the simplified model of (11) without confusion:

\[
\text{MCSLP: } x = \arg \min_{x \in \Pi} \left\{ C(x) := \sum_{j=1}^{d} s_j y(x-a_j(x)) \right\}. \tag{12}
\]

According to Proposition 1, it follows that CSLP (II), or equivalently MCSLP (12), is convex problem of \( x \).

### 3.2.1. LVI Reformulation of MCSLP

For the gauge \( y(\cdot) \) in (12) which is defined by (1), there exists a dual gauge, \( y^d(\cdot) \), defined by

\[
y^d(z) = \max \left\{ z^T x \mid y(x) \leq 1 \right\} \tag{13}
\]

Let \( B^d \) be the unit ball of the dual gauge \( y^d(\cdot) \), which is also convex and compact and exactly the polar set of \( B \). The dual gauge of \( y^d(\cdot) \) is again \( y(\cdot) \), that is,

\[
y(x) = \max \left\{ z^T x \mid y^d(x) \leq 1 \right\}, \tag{14}
\]

which can also be rewritten as

\[
y(x) = \max_{x \in B^d} z^T x. \tag{15}
\]

For more details about gauge and dual gauge, as well as their unit balls, the readers can be referred to [27].

According to (15), MCSLP (12) is equivalent to the following min-max problem:

\[
\min_{x \in \Pi} \max_{z, e \in B^d} \sum_{j=1}^{d} z_j^T (x-a_j(x)), \tag{16}
\]

where each \( z_j \) is a vector in \( B^d_j = \{ \xi \in R^n \mid y^d(\xi) \leq s_j \} \). Since \( a_j(x) \) is the closest point to \( x \) in \( A_j \), we can introduce \( y_j \in A_j \) to replace \( a_j(x) \). Hence, (16) is equivalent to

\[
\min_{x \in \Pi, y \in A_j} \max_{e, e \in B^d_j} \sum_{j=1}^{d} z_j^T (x-y_j). \tag{17}
\]

### Theorem 3

The MCSLP (12) and the LVI (21)-(22) are equivalent in the sense that they have the same solution of \( x \in \Pi \).
Proof. Since the MCSLP (12) is equivalent to (17), we need to prove that (17) and the LVI (21)-(22) are equivalent. In the following, we will prove that \((x^*, y^*, z^*)\) is a solution of (17) if and only if \((x^*, y^*, z^*)\) is a solution of LVI (21)-(22).

Let \((x^*, y^*, z^*)\) be the solution of (17); then, according to the deduction above, we know that \((x^*, y^*, z^*)\) is the solution of LVI (21)-(22).

On the other hand, let \((x^*, y^*, z^*)\) be the solution of LVI (21)-(22) and \(\phi(x, y, z) = \sum_{j=1}^{d} z^*_j (x - y)_j\); then, the inequality (19) is true, which means that \((x^*, y^*, z^*)\) is the saddle point of \(\phi(x, y, z)\).

Note that \((x^*, y^*, z^*)\) is the saddle point of \(\phi(x, y, z)\) if and only if \((x^*, y^*, z^*) \in \Omega\) and

\[
\max_{z \in B^d} \phi(x^*, y^*, z) = \phi(x^*, y^*, z^*) = \min_{x \in \Pi, y \in Y} \phi(x, y, z^*),
\]

which implies that

\[
\min_{x \in \Pi, y \in Y} \max_{z \in B^d} \phi(x, y, z) \leq \max_{z \in B^d} \phi(x^*, y^*, z) \leq \phi(x^*, y^*, z^*) = \min_{x \in \Pi, y \in Y} \phi(x, y, z^*) = \min_{x \in \Pi, y \in Y} \phi(x, y, z).
\]

On the other hand, let \(z'\) be any vector in \(B^d\); then, we have

\[
\min_{x \in \Pi, y \in Y} \phi(x, y, z') \leq \min_{x \in \Pi, y \in Y, z \in B^d} \max_{z \in B^d} \phi(x, y, z).
\]

We choose \(z'\) in (25) as the maximum point of the left term over \(z' \in B^d\); then,

\[
\max_{z \in B^d} \min_{x \in \Pi, y \in Y} \phi(x, y, z) \leq \min_{x \in \Pi, y \in Y, z \in B^d} \max_{z \in B^d} \phi(x, y, z).
\]

Combining (24) and (26), it follows that all terms in (24) are equal, and therefore,

\[
\phi(x^*, y^*, z^*) = \min_{x \in \Pi, y \in Y} \max_{z \in B^d} \phi(x, y, z),
\]

which implies that \((x^*, y^*, z^*)\) is the solution of (17). \(\square\)

Remark 4. It is worth pointing out that the equivalence between the MCSLP (12) and the linear variational inequality (21)-(22) can also be obtained by the duality theory and the variable \(z_j\) and the set \(B^d_{z_j}\) \((j = 1, \ldots, d)\) in (16) are, respectively, the dual vector and dual ball in the space \(R^p\) which satisfy \(z_j \in B^d_{z_j}\).

The norms especially \(l_1, l_2\), and \(l_\infty\) are frequently used to measure distances in the literature; see, for example, [18, 19]. It should be noted that the gauge used in this paper is an extension of norms which include \(l_1, l_2\), and \(l_\infty\). When the gauge \(\gamma(\cdot)\) is chosen as the \(l_1, l_2\), and \(l_\infty\)-norm, the dual gauge \(\gamma^d(\cdot)\) will be the \(l_\infty, l_2\), and \(l_1\)-norm, respectively. Let

\[
B_{s/z} = \left\{ \xi \in R^p : \|\xi\|_2 \leq s_j \right\}, \quad \mathcal{B}_2 = B_{s_1}\times\cdots\times B_{s_d}, \tag{28}
\]

where \(\| \cdot \|_2\) is the Euclidean norm; then, as a particular case of our single-source location problem (11), the problem under \(l_2\)-norm analyzed in [6] can be reformulated into the LVI (21)-(22) in which \(\mathcal{B}^d\) is equal to \(\mathcal{B}_2\) and \(\Pi = R^p\).

Further let

\[
B_{s_1} = \left\{ \xi \in R^p : \|\xi\|_1 \leq s_j \right\}, \quad B_{s_\infty} = \left\{ \xi \in R^p : \|\xi\|_\infty \leq s_j \right\}, \tag{29}
\]

where \(\| \cdot \|_1\) and \(\| \cdot \|_\infty\) are the \(l_1, l_\infty\)-norm, respectively, and

\[
\mathcal{B}_1 = B_{s_1}\times\cdots\times B_{s_1}, \quad \mathcal{B}_\infty = B_{s_\infty}\times\cdots\times B_{s_\infty}. \tag{30}
\]

Then, the CSLP (11) under \(l_1\)-norm (the minimum model discussed in [16]) and the CSLP under \(l_\infty\)-norm are equivalent to the LVI (21)-(22), where \(\mathcal{B}^d\) is, respectively, equal to \(\mathcal{B}_\infty\) and \(\mathcal{B}_1\) and the locational constraints \(\Pi\) are both \(R^p\).

3.2.2. A Projection-Contraction Method for LVI (21)-(22).

Among numerous effective numerical algorithms for solving VI, especially LVI, one famous one is the projection-contraction (PC) method which was originally proposed by Uzawa [46]. The attractive characteristics of the PC method, for example, simpleness and effectiveness, have motivated further development on VI especially in computational aspects; see, for example, [39, 47–49]. In this section, we will summarize some concepts and results about linear variational inequalities and then adopt the projection-contraction method in [48] for solving LVI (21)-(22). More details about the proposed PC method can be referred to [48].

Let \(W\) be a nonempty closed convex set of \(R^d\). For a given \(v \in R^d\), the projection of \(v\) onto \(W\) denoted by \(P_W(v)\) is the unique solution of the following problem:

\[
P_W(v) = \text{argmin} \{ ||u - v||_2 \mid u \in W \}. \tag{31}
\]

A basic proposition of the projection mapping on a closed convex set is

\[
(v - P_W(v))^T (u - P_W(v)) \leq 0, \quad \forall v \in R^d, \forall u \in W. \tag{32}
\]

It is well known (see, e.g., [50]) that for any \(\beta > 0\), \(u^*\) is the solution of LVI(\(\Omega, M, q\)) if and only if

\[
e(u^*, \beta) := u^* - P_\Omega [u^* - \beta (Mu^* + q)] = 0. \tag{33}
\]

In the literature of variational inequalities, \(e(u, \beta)\) is usually called the error bound of LVI, and it quantitatively measures how much \(u^*\) fails to be the solution of LVI(\(\Omega, M, q\)). Therefore, \(e(u, \beta)\) can serve as the stopping criterion for solving LVI(\(\Omega, M, q\)) iteratively.
Let
\[ e(u) = e(u, 1), \quad g(u) = M^T e(u) + (Mu + q), \]
and \( \Omega^* \) be the set of solutions of LVI(\( \Omega, M, q \)); then, for the positive semidefinite (not necessarily symmetric) matrix \( M \), the following theorem can be obtained.

**Theorem 5** (Lemma 1 and Theorem 2 in [48]). Let \( u \in \Omega \), \( u^* \in \Omega^* \), \( g(u) \), and \( \varphi(u) \) be defined as (34). Then, it holds that
\[
(u - u^*)^T g(u) \geq \varphi(u) \geq \|e(u)\|^2. \tag{35}
\]

For \( u \in \Omega \setminus \Omega^* \), it follows from Theorem 5 that \(-g(u)\) is a descent direction of the unknown function \( \|u - u^*\|^2 \).

We state the projection-contraction method in [48] as follows which is used to solve the LVI (21)-(22).

**Algorithm 6** (the projection-contraction method for LVI (21)-(22)).

**Step 0.** Let \( \varepsilon > 0 \), \( \beta = 1, \alpha_1, \alpha_2 \) \((\alpha_1 > \alpha_2)\) and \( u^0 \in \Omega \). Set \( k = 0 \).

**Step 1.** Calculate \( e(u^k) \). If \( \|e(u^k)\| < \varepsilon \), stop.

**Step 2.** Calculate \( g(u^k) \) and set \( \alpha(u^k) \) as
\[
\alpha(u^k) = \frac{\|e(u^k)\|^2}{\|e(u^k)\|^2 + \|M^T e(u^k)\|^2}. \tag{36}
\]

**Step 3.** Calculate \( u^{k+1} \) as
\[
u^{k+1} = \Pi_\Omega \left[ u^k - \rho \alpha(u^k) g(u^k) \right], \quad \rho \in (0, 2). \tag{37}
\]

**Step 4.** Adjust \( \beta \) as follows
\[
\beta = \begin{cases} 
\frac{3}{2} \beta & \sqrt{\alpha(u^k)} \geq \alpha_1, \\
\frac{2}{3} \beta & \sqrt{\alpha(u^k)} \leq \alpha_2, \\
\beta & \text{otherwise,}
\end{cases} \tag{38}
\]
and set
\[
M = \beta M, \quad q = \beta q. \tag{39}
\]

Let \( k = k + 1 \) and go to Step 1.

**Remark.** In Step 4 of Algorithm 6, the parameter \( \beta \) is self-adaptive during the iterations according to the value of \( \alpha(u^k) \). Note that \( M \) is skew-symmetric, and thus, \( \alpha(u^k) \) can also be rewritten as
\[
\alpha(u^k) = \frac{\|e(u^k)\|^2}{\left(\|e(u^k)\|^2 + \|M^T e(u^k)\|^2\right)^{1/2}}. \tag{40}
\]
which is shown to be in \([0, 1]\). It follows from (39)-(40) that the two terms \( \|e(u^k)\|^2 \) and \( \|M^T e(u^k)\|^2 \) in the denominator of \( \alpha(u^k) \) are balanced by the self-adaptive parameter \( \beta \).

**Theorem 8** (Theorem 3 in [48]). Let \( u^* \) be a solution of LVI (21)-(22); then, the sequence \( \{u^k\} \) generated by Algorithm 6 satisfies
\[
\|u^{k+1} - u^*\|^2 \leq \|u^k - u^*\|^2 - \frac{\rho(2 - \rho)}{\|I + M^T M\|^2} \|e(u^k)\|^2. \tag{41}
\]

As a result, \( \{e(u^k)\} \) converges to zero, and thus, all accumulation points of \( \{u^k\} \) are the solutions of LVI (21)-(22). However, it follows from (41) that \( \|u^{k+1} - u^*\| \leq \|u^k - u^*\| \), which implies that \( \{u^k\} \) has only one accumulation point. Thus, the sequence \( \{u^k\} \) generated by Algorithm 6 will converge to the optimal solution of LVI (21)-(22).

4. A Location-Allocation Heuristic for CMLP (9)

Recall the fact that for the well-known multi-source Weber problem (MWP), heuristics algorithms are extremely popular and frequently used for overcoming its nonconvexity and NP-hardness. In particular, the location-allocation heuristic algorithm has drawn much attention ever since its presentation by Cooper [34]. Note that the targeted CMLP (9) is an extension of the MWP and it is harder than MWP, and thus, in this paper, we also focus on applying the location-allocation heuristic algorithm for solving the CMLP in the spirit of Cooper’s work.

Our previous analysis indicates that each iteration of the location-allocation heuristic algorithm to be presented consists of an allocation phase and a location phase. The allocation task generates a new disjoint partition of all the regional customers according to the principle of NCR as in the Cooper algorithm, and the location phase identifies the optimal locations for the current partition of customers via implementing the variational inequality approach for solving \( m \) CSLPs.

Mark that the CMLP (9) differs from MWP mainly in that the customers are represented by regions rather than points. Consequently, the CSLPs involved in the location phase are constrained location problems with regional demand and closest distances under gauge. No doubt that the numerical implementation of the heuristic algorithm to be presented is expected to be more complicated than the location-allocation algorithms for MWP. Therefore, how to accelerate the convergence of the proposed heuristic deserves further consideration. To achieve this objective, we here consider a particular strategy for the initial partition of regional customers or the initial locations of facilities. In practical implementation, we suggest to choose the solution of the following constrained multi-source Weber problem (CMWP) as the initial locations of facilities for CMLP:

\[
\text{CMWP: } \min_{(x_1, \ldots, x_m) \in \Pi_1 \times \cdots \times \Pi_m} C'(X) = \sum_{j=1}^n s_j \min_{1 \leq i \leq m} g(x_i, g_j), \tag{42}
\]
where \( g_j \)’s are geometric centers of the regional customers. Then, we apply the NCR to determine an initial partition of regional customers according to the solution of (42). For solving the constrained multi-source Weber problem (42), we
employ the location-allocation heuristic algorithm in [35]. As we will show by numerical experiments, this initialization strategy can accelerate the convergence of the proposed algorithm greatly.

In the spirit of Cooper’s work, the new heuristic algorithm is ready to be presented for solving the targeted CMLP (9), and its iterative framework can be elaborated as follows.

**Algorithm 9** (a location-allocation heuristic algorithm for CMLP). *Initialization*: Solve (42) by the location-allocation heuristic in [35] and use its heuristic solutions as the initialization. The algorithm greatly.

**Step 1 (location phase).** Solve the involved CSLP (II) and find the location of facility \( x^k \) for \( \Lambda^k \) by the variational inequality approach. Denote \( x^k = (x_1^k, \ldots, x_m^k)^T \).

**Step 2 (allocation phase).** Update the partition of regional customers \( \Lambda \) from \( \Lambda^k \) to \( \Lambda^{k+1} \) based on the spirit of NCR heuristic.

**Step 3** If \( \| X^k - X^{k-1} \| < \epsilon \), the current locations and partition are heuristic locations of facilities and heuristic partition of customers. Otherwise, set \( k = k + 1 \) and go to Step 1.

**Remark 10.** At the \((k + 1)\)th iteration, it is recommended to use \( x^k \) (and the corresponding \( y \) and \( z \)) in Step 1 as the initial iterate in the variational inequality approach for solving \( x^{k+1} \) \((i = 1, \ldots, m)\), considering the fact that \( \Lambda^k \) usually differs from \( \Lambda^{k-1} \) slightly in practical implementation.

**Remark 11.** Compared to the main body of the proposed location-allocation heuristic algorithm, the workload of the initialization is relatively less. However, this initialization strategy can reduce its number of iterations and computing time, which will be verified by the numerical experiments to be reported in Section 6.2. Hence, the convergence of the proposed algorithm is accelerated greatly by this initialization strategy.

5. Convergence of the Proposed Heuristic Algorithm

In this section, we analyze the convergence of the proposed location-allocation heuristic (Algorithm 9). For simplification of our discussion, some notations are introduced as follows. Let \( A = A_1 \times \cdots \times A_m \), and recall \( \Pi = \Pi_1 \times \cdots \times \Pi_m \). For any \( X = (x_1^T, \ldots, x_m^T)^T \in \Pi \) and \( C = (c_1^T, \ldots, c_m^T)^T \in A \), we can define an ordered pair \((X, C)\) and we can also define the function \( \omega(X, C) \), in the current partition of customers as follows:

\[
\omega(X, C) = \sum_{j=1}^m \sum_{i=1}^n \omega_{ij} (x_i - c_j) = \sum_{j=1}^m \sum_{i=1}^m s_j y (x_i - c_j),
\]

which represents the objective functional value of CMLP (9) at \((X, C)\).

During the implementation of Algorithm 9, we denote the map \( \mathcal{A} : \Pi \times A \rightarrow \Pi \times A \) as the allocation operation in Step 1 and the map \( \mathcal{A} : \Pi \times A \rightarrow \Pi \times A \) as the allocation operation in the Step 2. It follows that

\[
\mathcal{A} \left( X^k, C^k \right) = \left( X^{k+1}, C^{k+1} \right),
\]

where \( X^k \) and \( X^{k+1} \) are, respectively, the locations of facilities in the \( k \)th and \((k + 1)\)th iteration, \( C^k \) is the variable of the closest points to \( X^k \) in the partition of \( \Lambda^k \), \( C^{k+1} \) is the closest points to the new \( X^{k+1} \) in the partition of \( \Lambda^{k+1} \). Then, the iterate scheme of the location-allocation heuristic is

\[
\left( X^{k+1}, C^{k+1} \right) = \mathcal{A} \mathcal{L} \left( X^k, C^k \right).
\]

Let \( S(X^0, C^0) \) denote the iterative sequence generated by the location-allocation heuristic for CMLP with the initial iterate \((X^0, C^0)\). During the implementation of the proposed heuristic algorithm, we choose the initial iterate in location phase for solving CSLP as Remark 10 indicates. We first give the following proposition which reveals the monotonicity of the generated sequence \( S(X^0, C^0) \).

**Proposition 12.** \( S(X^0, C^0) \) is strictly monotone in the sense that \( \omega(X^{k+1}, C^{k+1}) < \omega(X^k, C^k) \) if \( X^{k+1} \neq X^k \).

**Proof.** Since \( X^{k+1} \neq X^k \), there exists at least one \( i \in \mathcal{M} \) such that \( x_i^{k+1} \neq x_i^k \). For such \( i \)'s according to the following convex optimization problem

\[
x_i^{k+1} = \arg \min_{x \in \Pi_i} \left\{ C_{j_i}^{k+1} (x) = \sum_{j \in \mathcal{M} \setminus \{i\}, x \in \Lambda_j} s_j y (x - a_j (x)) \right\},
\]

we have

\[
\omega(X^{k+1}, C^{k+1}) < \omega(X^k, C^k).
\]

Based on Remark 10, we know that if \( x_i^k \) is the solution of (46), then \( x_i^{k+1} \) will be equal to \( x_i^k \). Therefore, \( x_i^{k+1} \neq x_i^k \) implies that \( x_i^k \) is not the solution of (46), and thus, \( C_i^{k+1} (X^{k+1}) < C_i^k (x^k) \). It follows that

\[
\omega(X^{k+1}, C^{k+1}) < \omega(X^k, C^k).
\]

On the other hand, based on the principle of NCR in the allocation phase of Algorithm 9, we also have

\[
\omega(X^{k+1}, C^{k+1}) \leq \omega(X^{k+1}, C^{k+1}),
\]
By Combining (48) and (49), it follows that
\[
\omega(X^{k+1}, C^{k+1}) < \omega(X^k, C^k) .
\] (50)

The proof is complete. \(\Box\)

Based on the monotonicity of the generated sequence 
S(X0, C0), the following theorem can be proved.

**Theorem 13.** Let \(\{S_k\} := S(X^0, C^0)\). Then, the generated sequence \(\{S_k\}\) satisfies that

1. \(\omega(S_k) \rightarrow \omega(S)\) for some \(S \in \Pi \times A\),
2. all accumulation points of \(\{S_k\}\) have the same objective functional values.

**Proof.** After a finite number of iterations, if \(X^{J+1} = X^J\), then the iterates after \(S_J\) will be constant, and thus, \(\{S_k\}\) is convergent to \((X^J, C^J) \in \Pi \times A\), and the two assertions are both true.

Below, we will discuss the case that \(X^{J+1} \neq X^k\) for any \(k \in N\). First, we prove the first assertion. Since \(S_k \in \Pi \times A\) and \(\Pi \times A\) is a compact space, it follows from the Bolzano-Weierstrass theorem that there exists a subsequence of \(\{S_k\}\) which, say \(\{S_k\}_K\), converges to an element \(S \in \Pi \times A\); that is,
\[
\lim_{K \rightarrow \infty} \{S_k\}_K \rightarrow S, \quad S \in \Pi \times A.
\] (51)

Note that \(\omega(X, C)\) is a continuous function according to (43); then,
\[
\lim_{K \rightarrow \infty} \omega(\{S_k\}_K) \rightarrow \omega(S), \quad S \in \Pi \times A.
\] (52)

Due to that \(\{\omega(S_k)\}\) is a monotone sequence (Proposition 12) and has lower bound, then \(\omega(S_k)\) is convergent. Thus, any subsequence of \(\{\omega(S_k)\}\) will be convergent to the same value. Note that \(\{\omega(\{S_k\}_K)\}\) is a subsequence of \(\{\omega(S_k)\}\) and it is convergent to \(\omega(S)\); then, it follows that
\[
\lim_{K \rightarrow \infty} \omega(S_k) \rightarrow \omega(S), \quad S \in \Pi \times A.
\] (53)

The second assertion can easily be proved. Let \(P\) be an accumulation point of \(\{S_k\}\); then, there exists one subsequence \(\{S_k\}_K\) which converges to \(P\), and due to the continuity of \(\omega(X, C)\), we have
\[
\omega(\{S_k\}_K) \rightarrow \omega(P).
\] (54)

The first assertion has shown that \(\{\omega(S_k)\}\) is convergent, and note that \(\{\omega(\{S_k\}_K)\}\) is a subsequence of \(\{\omega(S_k)\}\); then, it follows that
\[
\omega(P) = \lim_{K' \rightarrow \infty} \omega(\{S_k\}_K) = \lim_{K \rightarrow \infty} \omega(S_k).
\] (55)

Thus, all accumulation points of \(\{S_k\}\) have the same objective functional values equal to \(\lim_{K \rightarrow \infty} \omega(S_k)\). \(\Box\)

**Lemma 14.** \(J: \Pi \times A \rightarrow \Pi \times A\) which is defined in (44) is a closed map over \(\Pi \times A\).

**Proof.** Note that the CSLP (II) is a convex problem, then
\[
\text{argmin}_{x \in \Pi_i} \left\{ \sum_{j \in A_i} s_{ij} \min_{y \in A_j} \gamma(x_i - q_j) \right\},
\] (56)

\[i = 1, 2, \ldots, m,
\]

are continuous. Since \(\Pi \times A\) is a compact space and also a Hausdorff space and every continuous map from a compact space to a Hausdorff space is closed, it follows that \(J\) is closed over \(\Pi \times A\). \(\Box\)

**Lemma 15.** Let \(v_0\) be a given vector in \(\Pi \times A\) and \(\Delta := \{v \in \Pi \times A | \omega(v) \leq \omega(v_0)\}\). Then, \(\Delta\) is a compact set.

**Proof.** It is known that every closed subset of a compact space is also compact, and therefore, it is enough to prove that \(\Delta\) is a closed set.

For any sequence \(\{v_k\}\) with \(v_k \in \Delta\), since \(\Pi \times A\) is compact, according to Bolzano-Weierstrass, there exists a convergent subsequence \(\{v_k\}_K\) of \(\{v_k\}\) such that
\[
\lim_{K \rightarrow \infty} \{v_k\}_K \rightarrow v.
\] (57)

Due to the continuity of \(\omega\), it follows that
\[
\lim_{K \rightarrow \infty} \omega(\{v_k\}_K) = \omega(v).
\] (58)

On the other hand, \(\{v_k\}_K \in \Delta\) implies
\[
\omega(\{v_k\}_K) \leq \omega(v_0).
\] (59)

By combining (58), (59), and the continuity of \(\omega\), the following inequality is obtained:
\[
\omega(v) \leq \omega(v_0),
\] (60)

and accordingly, \(v \in \Delta\). This means that \(\Delta\) is closed, and the proof is complete. \(\Box\)

Now, we are ready to prove the convergence of the proposed location-allocation heuristic (Algorithm 9). Let \(\Xi \subseteq \Pi \times A\) be the nonempty local solution set of CMLP (9). Recall that in the location-allocation Cooper algorithm for MWP, if \(X^{J+1} = X^J\) occurs after a finite number of iterations, the iterates after \(X^J\) will be constant. Then, no further improvement is possible for MWP, and it follows from [32, 34] that the \(X^J\) is a local solution of MWP. Similarly, in the proposed location-allocation heuristic algorithm for CMLP, if \(X^{J+1} = X^J\) occurs, the iterates after \(S_J = (X^J, C^J)\) will also be constant. Then, exactly as in the location-allocation Cooper algorithm for MWP, no further improvement is possible for CMLP, and a local solution, namely, \(S_J\), is obtained. Hence in this case, \(\{S_k\}\) is convergent to the \(S_J \in \Xi\). However, it is not assured that \(X^{J+1} = X^J\) always occurs during the implementation of Algorithm 9, and therefore, we assume that \(X^{k+1} \neq X^k\) for any \(k \in N\) and prove the convergence in this case.
Theorem 16. Assume that $X_k^{k+1} \neq X^k$ for any $k \in N$; then, all the accumulation points of the sequence $\{S_k\}$ belong to $\Xi$.

Proof. Let $S$ be an accumulation point of $\{S_k\}$. Due to $S_k \in \Pi \times A$ and the compactness of $\Pi \times A$, we know that (1) $S \in \Pi \times A$ and (2) there exists a subsequence $\{S_k\}_K$ which is convergent to $S$. According to Theorem 13, we know that

$$\lim_{k \to \infty} \omega(S_k) = \omega(S), \quad S \in \Pi \times A. \tag{61}$$

So, it is enough to prove $S \in \Xi$. We prove this by contradiction. Assume that $S \notin \Xi$; that is, $S$ is not a solution, and we consider the subsequence $\{S_k\}_{K'}$. Denote $\Delta = \{v \in \Pi \times A | \omega(v) \leq \omega(S_0)\}$. Due to Proposition 12, it follows that for all $k \in N$ we have $(X^{k+1}, C_k) \in \Delta$ and $(X^{k+1}, C^{k+1}) \in \Delta$. According to Lemma 15, $\Delta$ is compact, and thus, there exists $K' \subset K$ such that

$$\lim_{K' \to \infty} (X^{k+1}, C_k)_{K'} = v_1, \quad \lim_{K' \to \infty} (X^{k+1}, C^{k+1})_{K'} = v_2. \tag{62}$$

According to Lemma 14, the map $\mathcal{L}$ is closed at $S \in \Pi \times A$; then, it follows that $v_1 = \mathcal{L}(S)$. Further, due to $S \notin \Xi$, $v_1$ will be not equal to $S$. Otherwise, we can choose $S$ as the initial iterate of the location-allocation heuristic algorithm, then, the sequence generated by the algorithm will be constant. It follows from the first case (i.e., $X^{k+1} = X^l$) that $S$ will be a local solution, which contradicts with $S \notin \Xi$. Therefore, we can obtain $v_1 \neq S$. Together with the monotone proposition of $\mathcal{L}$ (48), we have the inequality

$$\omega(v_1) < \omega(S). \tag{63}$$

On the other hand, note that $\omega(X^{k+1}, C_k^k) = (X^{k+1}, C^{k+1})$; then, by the monotonicity of $\omega$ (49), it follows that

$$\omega(X^{k+1}, C^{k+1})_{K'} \leq \omega(X^{k+1}, C_k^k)_{K'}, \tag{64}$$

and thus, by taking the limit for (64) and by the continuity of $\omega$, we know $\omega(v_2) \leq \omega(v_1)$. Combining this with (63), we obtain

$$\omega(v_2) < \omega(S). \tag{65}$$

However, note that $v_2$ and $S$ are two accumulation points of $\{S_k\}$, and according to the second assertion of Theorem 13, $\omega(v_2) = \omega(S)$, which will contradict with (65). Therefore, our assumption is wrong, and thus, $S \in \Xi$. \hfill $\square$

As a result, we have the following convergence theorem for the sequence generated by the proposed location-allocation algorithm.

Theorem 17. The sequence $S(X_0, C_0^k)$ generated by the proposed location-allocation heuristic algorithm either converges to a point in $\Xi$ or all accumulation points of $S(X_0, C_0^k)$ belong to $\Xi$.

6. Numerical Results

This section reports some preliminary numerical results to verify the theoretical assertions proved in previous sections. Section 3.1, reports some numerical results of the proposed variational inequality approach for the CSLP (II) (or equivalently (12)) which includes (1) the results of the comparison between our approach and the Weiszfeld-type method by solving the example in [6] and some randomly generated unconstrained examples under Euclidean distances and (2) the results of our approach for solving some randomly generated constrained examples under a gauge. These numerical results demonstrate the efficiency of the proposed variational inequality approach for CSLP. In the second subsection, we apply the proposed location-allocation heuristic algorithm to solve some randomly generated examples of the CMLP (9).

In particular, the effectiveness of the initialization strategy adopted in this heuristic for accelerating convergence will be justified. All the programming codes are written by MATLAB 2012b and were run on an ASUS notebook (Intel Core2 Duo T6670 2.20 GHz).

6.1. Numerical Results of Variational Inequality Approach for CSLP. When applying the variational inequality approach for solving CSLP and MCSLP (12), theoretically, the initial iteration $u^0$ in Algorithm 6 can be chosen arbitrarily in $\Omega$. In practical implementation, however, we choose $u^0$ judiciously similar to the initialization strategy in the location-allocation heuristic: let $g_j(j = 1, \ldots, d)$ be the centers of regional customers, solve the following single-source Weber problem (SWP):

$$x^* = \arg\min_{x \in \Pi} \left\{ \sum_{j=1}^{d} \gamma(x-g_j) \right\} \tag{66}$$

by the projection-contraction method in [35], and then use its solution as the initial iterate for Algorithm 6. We call this the initialization strategy of variational inequality approach. In addition, throughout our experiments of VI approach, the $\alpha_1$ and $\alpha_2$ in Algorithm 6 are chosen as 1 and 0, respectively.

We first solve the example given in [16] by the proposed variational inequality approach and the Weiszfeld-type method in [16].

Example 18. Here, $d = 5$; that is, there are five regional customers, and all customers are unit squares whose sides are parallel to the axes. The geometric centers of the five customers are (0.5, 0.5), (4.5, 0.5), (0.5, 2.5), (2.5, 2.5), (4.5, 2.5), and $s_j = 1, j = 1, \ldots, 5$.

In order to clarify the comparison of two methods, we choose the same stopping criterion as $\|x^{k+1} - x^k\| \leq 10^{-4}$ (throughout this section, $\|\cdot\|$ is the $l_\infty$-norm). We test this example for 100 times with the same initial iterate for the two methods which is randomly generated in $[0, 5] \times [0, 3]$, and the numerical results including the location of new facility, the closest points to the facility, number of iterations, and computing time in units of second are reported in Table I.
According to Table 1, it follows that both methods can get the optimal location of the new facility. Though our variational inequality approach needs smaller iteration numbers and less computing time, both methods are efficient for solving Example 1 given in [6].

Recall that the sequence generated by the Weiszfeld-type method in [16] is possible to be convergent to a nonoptimal point on the boundary of the regional customer, as indicated in [16]. The variational inequality approach, however, can obtain the optimal location of the new facility, which is guaranteed by the theoretical analysis in Section 3.2. To illustrate this, we compare two methods by solving the following particular example.

**Example 19.** Similar to Example 18, the number of customers  $d = 5$, and all customers are unit squares whose edges are parallel to the axes. Let $d_i$ be the distance between any two neighboring customers, and we set $d_i$ equal to $1, 0.1, 0.01, \text{and }0.001$, respectively. The weights $s_j$ ($j = 1, \ldots, 5$) are randomly generated in the area of regional customers.

Note that in Example 19 the parameter $d_i$ reflects how close the customers are away from its neighborhoods. We test this example for a large number of times with the stopping criterion $\|x^{k+1} - x^k\| \leq 10^{-4}$, and the average numerical results are reported in Table 2. In this table, each row reports the average results by testing Example 19 for one hundred times. The column of “No. of Iter.” gives the average iteration times of initialization in the variational inequality approach, and the column of “No. of Iter.” reports the average iteration times of both methods. The two columns of “CPU” give the average computing time in units of second for variational inequality approach (including the computing time for initialization) and Weiszfeld-type method, respectively. The columns of “Obj.” give the average objective functional value obtained by the two methods, and the column of “Improve. Percent” gives the improvement percentage in objective functional values of the VI approach to Weiszfeld-type method. Remark that the convergence of VI approach to the optimal location of new facility is guaranteed, and then the column of “Freq. Num.” reports the frequency among one hundred times that the Weiszfeld-type method can get the same solution as VI approach; that is, it does not converge to the nonoptimal solution on the boundary of the customer.

According to Table 2, it follows that both the VI approach and the Weiszfeld-type method are efficient for solving this particular example, and both of them need a small number of iterations and little computing time. In comparison of two methods, we can find that VI approach needs more iteration times and computing time than Weiszfeld-type method. From the column of “Improve. Percent,” however, we can conclude that VI approach can obtain a better solution (in fact, the solution obtained by VI approach is the optimal location of new facility) than Weiszfeld-type method. In addition, according to the last column, we find that when $d_i$ decreases, that is, the customers become closer and closer, the frequency that Weiszfeld-type method obtains the optimal solution gets smaller and smaller. When $d_i$ is 0.001, which implies that the customers are quite close to the neighborhoods, this frequency is totally less than 20. In other words, for this particular example with $d_i = 0.001$, the sequence generated by Weiszfeld-type method has a great possibility (more than 80%) to be convergent to a nonoptimal solution which is on the boundary of the customer. On the contrary, when $d_i$ is 1, which means that the customers are enough far away from one another, Weiszfeld-type method can obtain the optimal location of facility in most cases, and the frequency even exceeds 90.

Since our main effort in this paper is to solve the general location problem under gauge and locational constraint, it is necessary to apply the variational inequality approach to solve some CSLPs. In particular, we test a large number of randomly generated CSLPs with the number of customers $d$ from 10 to 2000. In the experiments, all regional customers are assumed to be square units, and their edges are parallel to the coordinate axes. The geometric centers of all regional customers are randomly generated in $[-100, 100]^2$; the weights of the regional customer are all randomly chosen in (1.5); the locational constraint is $|x - O| \leq r$, where the center $O$ is randomly generated in $[-100, 100]^2$, and the radius $r$ is randomly generated in (1.5); the stopping criterion of VI approach is chosen as

$$\|x^{k+1} - x^k\| \leq 10^{-4},$$

$$\|e(u^{k+1})\| \leq 10^{-4},$$

and the initial iterate is randomly generated in $[-100, 100]^2$; the gauge $\gamma(\cdot)$ is generated with the unit ball set as

$$9\left(x + \frac{2}{3}y^2 + 12y^2 = 16\right).$$

For each $d$, we test one hundred randomly generated CSLPs, and the average numerical results are reported in Table 3. To illustrate the effect of the initialization strategy of VI approach, we also report the results of VI approach without the initialization strategy. The columns of “VI approach with Initial.” and “VI approach without Initial.”, respectively, report the average number of iterations and average computing time of variational inequality approach with and without the initialization strategy.
Table 2: Numerical results of VI approach and Weiszfeld-type method for Example 19.

| $d_1$ | No. of Iter. | VI approach | Weiszfeld-type method | Impro. percent | Freq. num. |
|-------|-------------|-------------|-----------------------|----------------|-----------|
|       | No. of Iter. | CPU | Obj. | No. of Iter. | CPU | Obj. |               |           |           |
| 1     |              |         |     |              |         |     |               |           |           |

| 2000  | 281.59       | 245.5680 | 346.52 | 295.2305 |

According to Table 3, it is easy to conclude that the variational inequality approach is effective for solving CSLP under gauge considering the difficulty of this problem. In addition, the number of iterations of “VI approach with Initial.” is less than that of “VI approach without Initial.”, which shows that the initialization strategy can accelerate the convergence of the variational inequality approach. This strategy, however, does not necessarily reduce the computing time of VI approach, especially when $d$ is small, for example, $d = 10, 20, 50,$ and 100, which can be explained as follows. When the number of customers $d$ is small, the variational inequality problem is small scale, and thus, it can be solved in a short time. In this case, the computational workload of initialization plays an important role in the total workload, and therefore, the computing time of “VI approach with Initial.” is greater than that of “VI approach without Initial.” due to the computational iterations for initialization. With $d$ increasing, the scale of VI problem as well as the number of iterations becomes larger. Then, in the comparison of the workload of VI approach, the workload of initialization can almost be ignored, and therefore, the computing time of “VI approach with Initial.” will be smaller than that of “VI approach without Initial.” As a matter of fact, Table 3 reveals the computational necessity of the initialization strategy of variational inequality approach for large-scale CSLP; for example, the iteration number and computing time are reduced about $1/5$ by the initialization strategy when $d = 2000$.

6.2. Numerical Results of Heuristic Algorithm for CMLP. This subsection applies the proposed location-allocation heuristic algorithm (Algorithm 9) to solve a large number of CMLPs.
Table 4: Numerical results of location-allocation heuristic for CMLP.

| n   | m   | Iter.<sub>0</sub> | Iter.<sub>0</sub>-PC | Iter. | Iter.-PC | CPU     | Iter. | Iter.-PC | CPU     |

(9) and also verifies the necessity of the initialization strategy in Algorithm 9. In the experiments, we again generate a large number of CMLPs with unit square customers and assume that the edges of these regions are parallel to the coordinate axes. The geometric centers of all the demand regions are randomly generated in $[-100, 100]^2$, and all the demands, $s_j (j = 1, 2, \ldots, n)$, are randomly generated in $[1, 10]$. The gauge $\gamma(\cdot)$ is also defined with the unit ball set as (68). We test the scenario with $n = 100, 200, 500$, and 1000 and $m = 2, 4, 6, 8,$ and 10; the locational constraints are $\|x - O_j\| \leq r_j (j = 1, \ldots, m)$, where the radius $r_j$ is randomly generated in $[1, 10]$, and the center $O_j$ is given in advance as follows:

$m = 2: O_1 = (-50, 0)^T, O_2 = (50, 0)^T$;

$m = 4: O_1 = (-50, -50)^T, O_2 = (50, -50)^T, O_3 = (-50, 50)^T, O_4 = (50, 50)^T$;

$m = 6: O_1 = (-50, -50)^T, O_2 = (0, -50)^T, O_3 = (50, -50)^T, O_4 = (-50, -50)^T, O_5 = (0, 50)^T, O_6 = (50, 50)^T$;

$m = 8: O_1 = (-50, -50)^T, O_2 = (0, -50)^T, O_3 = (50, -50)^T, O_4 = (-50, -50)^T, O_5 = (0, 50)^T, O_6 = (50, 50)^T, O_7 = (-60, 0)^T, O_8 = (20, 0)^T, O_9 = (20, 0)^T, O_{10} = (60, 0)^T$.

(69)

The initial locations of facilities are randomly generated in $[-100, 100]^2$, and the stopping criterion used in Algorithms 6 and 9 is chosen as

$\|x^{k+1} - x^k\| < 10^{-4}$.

(70)

To show the significance of the initialization strategy, we compare the numerical performance of the location-allocation heuristic algorithm with initialization strategy (denoted by “Algorithm 9 with Initial.”) and without this initialization strategy (denoted by “Algorithm 9 without Initial.”). In the initialization step of Algorithm 9, the location-allocation algorithm in [35] is adopted to solve the corresponding CMWP (42), where a PC method is proposed to solve the subproblems in location phase, and the numbers of iterations of the algorithm in [35] (denoted by “Iter<sub>0</sub>”) and the average iteration numbers of PC method in one iteration of the algorithm (denoted by “Iter<sub>-PC</sub>-PC”) are reported. The columns of “Iter.” and “CPU,” respectively, report the number of iterations and computing time of Algorithm 9 with and without initialization strategy. Since the
efficiency of Algorithm 9 is mainly determined by the number of iterations of the variational inequality approach, we also report the average number of iterations of Algorithm 6 in one iteration of Algorithm 9 (denoted by "Iter.-PC"). For each given pair \((n, m)\), we test the CMLP for 100 times, and the computational performance is reported in Table 4.

It follows from Table 4 that the proposed location-allocation heuristic, with or without the initialization strategy, is capable of tackling the CMLP (9) efficiently, even for large-scale cases. Also, the necessity of the initialization strategy is evident. In fact, this strategy reduces the number of iterations and the computing time by about 50%.

Another interesting fact obtained from Table 4 deserves further illustration. Recall that with the number of new facilities \((m)\) increasing, the number of subproblems (CSLPs) in location phase increases too. According to Table 4, however, we find that for fixed number of customers \((n)\), with \(m\) increasing, the number of iterations for solving \(m\) CSLPs in one iteration of Algorithm 9 does not increase but almost decreases with \(m\), especially for large-scale CMLP. This can be illustrated roughly as follows. For fixed \(n\), when \(m\) increases, the average number of customers in each \(\Lambda_{i}^{k}\) becomes smaller, which implies that the scale of the involved CSLP (11) in location phase is smaller. According to Table 3, it follows that we need smaller number of iterations for small-scale CSLP, and thus, the total number of iterations for solving \(m\) CSLPs decreases. Similarly, due to the same reason, the computing time for solving CMLP also decreases with \(m\) increasing, as reported in the column of "CPU" in Table 4.

7. Conclusion

In this paper, we are interested in the locations of multiple facilities in the space \(R^p\) with regional demands, where the closest distance is used to measure the proximities between facilities and customers. With locational constraints introduced for the locations of new facilities and with the gauge used as the distance measuring function, the problem considered in this paper has much more applications in practice. Due to its nonconvexity and NP-hardness, a new location-allocation heuristic algorithm is proposed to solve this problem, and its convergence is proved under mild assumptions. Some preliminary numerical experiments are reported to verify the computational efficiency of the proposed algorithm.

We consider a class of linearly constrained separable convex programming problems whose objective functions are the sum of three convex functions without coupled variables. For those problems, Han and Yuan (2012) have shown that the sequence generated by the alternating direction method of multipliers (ADMM) with three blocks converges globally to their KKT points under some technical conditions. In this paper, a new proof of this result is found under new conditions which are much weaker than Han and Yuan’s assumptions. Moreover, in order to accelerate the ADMM with three blocks, we also propose a relaxed ADMM involving an additional computation of optimal step size and establish its global convergence under mild conditions.

1. Introduction

In various fields of applied mathematics and engineering, many problems can be equivalently formulated as a separable convex optimization problem with two blocks; that is, given two closed convex functions \( f_i : \mathbb{R}^{n_i} \rightarrow \mathbb{R} \cup \{+\infty\}, \ i = 1, 2 \), to find a solution pair \((x_1^*, x_2^*)\) of the following problem:

\[
\begin{align*}
\min & \quad f_1(x_1) + f_2(x_2) \\
\text{s.t.} & \quad A_1 x_1 + A_2 x_2 = b,
\end{align*}
\]

where \(A_i\) is a matrix in \(\mathbb{R}^{p \times n_i}, i = 1, 2\), and \(b\) is a vector in \(\mathbb{R}^p\). The classical alternating direction method of multipliers (ADMM) [1, 2] applied to problem (1) yields the following scheme:

\[
\begin{align*}
x_1^{k+1} &= \arg \min_{x_1 \in \mathbb{R}^{n_1}} f_1(x_1) - \left\langle A_1^T \lambda^k, x_1 \right\rangle \\
&\quad + \frac{\beta}{2} \left\| A_1 x_1 + A_2 x_2 - b \right\|^2,
\end{align*}
\]

where \(\lambda^k\) is a Lagrangian multiplier and \(\beta > 0\) is a penalty parameter. Possibly due to its simplicity and effectiveness, the ADMM with two blocks has received continuous attention both in theoretical and application domains. We refer to [3–8] for theoretical results on ADMM with two blocks and [9–13] for its efficient applications in high-dimensional statistics, compressive sensing, finance, image processing, and engineering, to name just a few.

In this paper, we concentrate on the linearly constrained convex programming problem with three blocks:

\[
\begin{align*}
\min & \quad f_1(x_1) + f_2(x_2) + f_3(x_3) \\
\text{s.t.} & \quad A_1 x_1 + A_2 x_2 + A_3 x_3 = b,
\end{align*}
\]
where \( f_3: \mathbb{R}^m \rightarrow \mathbb{R} \cup \{+\infty\} \) is a closed convex function and \( A_3 \) is a matrix in \( \mathbb{R}^{p \times m} \). For solving (3), a nature idea is to extend the ADMM with two blocks to the ADMM with three blocks in which the next iteration \((x_2^{k+1}, x_3^{k+1}, \lambda^{k+1})\) is updated by
\[
(x_2^{k+1}, x_3^{k+1}, \lambda^{k+1}) := (\tilde{x}_2^k, \tilde{x}_3^k, \tilde{\lambda}^k),
\]
where
\[
x_1^k = \arg \min_{x_1 \in \mathbb{R}^n} f_1(x_1) - \langle A_1^T \lambda^k, x_1 \rangle + \frac{\beta}{2} \| A_1 x_1 + A_2 x_2^k + A_3 x_3^k - b \|^2_2,
\]
\[
x_2^k = \arg \min_{x_2 \in \mathbb{R}^n} f_2(x_2) - \langle A_2^T \lambda^k, x_2 \rangle + \frac{\beta}{2} \| A_1 x_1^k + A_2 x_2 + A_3 x_3^k - b \|^2_2,
\]
\[
x_3^k = \arg \min_{x_3 \in \mathbb{R}^n} f_3(x_3) - \langle A_3^T \lambda^k, x_3 \rangle + \frac{\beta}{2} \| A_1 x_1^k + A_2 x_2^k + A_3 x_3 - b \|^2_2,
\]
and
\[
\tilde{\lambda}^k = \lambda^k - \beta (A_1 x_1^k + A_2 x_2^k + A_3 x_3^k - b).
\]

Similar to the ADMM with two blocks, the ADMM with three blocks has found numerous applications in a broad spectrum of areas, such as doubly nonnegative cone programming [14], high-dimensional statistics [15, 16], imaging science [17], and engineering [18]. Even though its numerical efficiency is clearly seen from those applications, the theoretical treatment of ADMM with three blocks is challenging and the convergence of the ADMM is still open given only the convex assumptions of the objective function. To alleviate this difficulty, the authors of [19, 20] proposed prediction-correction type methods to solve the general separable convex programming; however, numerical results show that the direct ADMM outperforms its variants substantially. Therefore, it is of great significance to investigate the theoretical performance of the ADMM with three blocks even only to provide sufficient conditions to guarantee the convergence. To the best of our knowledge, there exist only two works aiming to attack the convergence problem of the direct ADMM with three blocks. By using an error bound analysis method, Hong and Luo [21] proved the linear convergence of the ADMM with \( m \) blocks for sufficiently small \( \beta \) subject to some technical conditions. However, the sufficiently small requirement on \( \beta \) makes the algorithm difficult to implement. In [22], Han and Yuan employed a contractive analysis method to establish the convergence of ADMM under the strongly convex assumptions of \( f_i \) and the parameter \( \beta \) less than a threshold depending on all the strongly convex moduli. In this paper, we firstly prove the convergence of ADMM with three blocks under two conditions weaker than those of [22]. In our conditions, the threshold on the parameter \( \beta \) only relies on the strongly convex moduli of \( f_2 \) and \( f_3 \), and furthermore \( f_1 \) is not necessarily strongly convex in one of our conditions. Also, the restricted range of \( \beta \) in this paper is shown to be at least three times as big as that of [22].

In order to accelerate the ADMM with three blocks, we also propose a relaxed ADMM with three blocks which involves an additional computation of optimal step size. Specifically, with the triple \((x_2^k, x_3^k, \lambda^k)\), we first generate a predictor \((\tilde{x}_2^k, \tilde{x}_3^k, \tilde{\lambda}^k)\) according to (5) and then obtain \((x_2^{k+1}, x_3^{k+1}, \lambda^{k+1})\) in the next iteration by
\[
x_2^{k+1} = x_2^k - \gamma \alpha^*_k (\tilde{x}_2^k - x_2^k),
\]
\[
x_3^{k+1} = x_3^k - \gamma \alpha^*_k (\tilde{x}_3^k - x_3^k),
\]
\[
\lambda^{k+1} = \lambda^k - \gamma \alpha^*_k (\lambda^k - \tilde{\lambda}^k),
\]
where \( \gamma \in (0, 2) \) and \( \alpha^*_k \) is special step size defined in (43). The convergence of the relaxed ADMM is also established under mild conditions. We should mention that it is possible to modify the analyses given in this paper to be problems with more than three blocks of separability. But this is not the focus of this paper.

The remaining parts of this paper are organized as follows. In Section 2, we list some preliminaries on the strongly convex function, subdifferential, and the ADMM with three blocks. In Section 3, we first show the contractive property of the distance between the sequence generated by ADMM with three blocks and the solution set and then prove the convergence of ADMM under certain conditions. In Section 4, we extend the direct ADMM with three blocks to the relaxed ADMM with an optimal step size and establish its convergence under suitable conditions. We conclude our paper in Section 5.

**Notation.** For any positive integer \( m \), let \( I_m \) be the \( m \times m \) identity matrix. We use \( \| \cdot \| \) and \( \| \cdot \|_2 \) to denote the vector Euclidean norm and the spectral norm of matrices (defined as the maximum singular value of matrices). For any symmetric matrix \( S \in \mathbb{R}^{n \times n} \), we write \( \| x \|^2_S = x^T S x \) for any \( x \in \mathbb{R}^n \). \( G \) and \( M \) are two \((n_2 + n_3 + p) \times (n_2 + n_3 + p)\) matrices defined by
\[
G := \begin{pmatrix} \beta A_2^T A_2 & 0 & 0 \\ 0 & \beta A_3^T A_3 & 0 \\ 0 & 0 & I_p \end{pmatrix},
\]
\[
M := \begin{pmatrix} 2\beta A_2^T A_2 & 0 & 0 \\ 0 & 2\beta A_3^T A_3 & 0 \\ 0 & 0 & I_p \end{pmatrix},
\]
respectively. For given \( x_1 \in \mathbb{R}^n_+, x_2 \in \mathbb{R}^n_+, x_3 \in \mathbb{R}^n_+, \) and \( \lambda \in \mathbb{R}^p \), we frequently use \( u \) and \( v \) to denote the joint vectors of \( x_2, x_3, \lambda \) and \( x_1, x_2, x_3, \lambda \), respectively; that is,
\[
u = \begin{pmatrix} x_1^T \\ x_2^T \\ x_3^T \end{pmatrix}, 
\]
where \( \bar{u} \) and \( \bar{v} \) are the joint vectors corresponding to \( \bar{x}_2, \bar{x}_3, \bar{\lambda} \) and \( \bar{x}_1, \bar{x}_2, \bar{x}_3, \bar{\lambda} \).
2. Preliminaries

Throughout this paper, we assume \( f_i, \ i = 1, 2, 3, \) are strongly convex functions with modulus \( \mu_i \geq 0; \) that is

\[
f_i ((1 - \alpha) z + \alpha z') \leq (1 - \alpha) f_i (z) + \alpha f_i (z') - \frac{1}{2\mu_i} \alpha (1 - \alpha) \| z - z' \|^2, \quad \forall z, z' \in \mathbb{R}^n,
\]

for each \( i. \) Note that \( f_i \) is a strongly convex function with modulus 0 being equivalent to the convexity of \( f_i. \) Let \( x \) be a point of \( \text{dom}(f_j); \) the subdifferential of \( f_i \) at \( x \) is defined by

\[
\partial f_i (x) := \{ x^* \mid f (z) \geq f (x) + \langle x^*, z - x \rangle, \forall z \}.
\]

From Proposition 6 in [23], we know that, for each \( i, \partial f_i \) is strongly monotone with modulus \( \mu_i, \) which means

\[
\langle z_1 - z_2, x_1 - x_2 \rangle \geq \mu_i \| z_1 - z_2 \|^2 \geq 0, \quad \forall x_1, x_2, z_1, z_2 \in \partial f_i (x_1), z_2 \in \partial f_i (x_2).
\]

The next lemma introduced in [22] plays a key role in the convergence analysis of the ADMM and the relaxed ADMM with three blocks.

Lemma 1. Let \((x^*_1, x^*_2, x^*_3, \lambda^*)\) be any KKT point of problem (3). Let \( \overline{\nu} \) be generated by (5) from given \( u^k. \) Then, one has

\[
\langle \overline{u}^k - u^*, G (u^k - \overline{u}^k) \rangle \\
\geq \sum_{i=1}^{3} \mu_i \| x_i^k - x_i^* \|^2 + \lambda^k - \overline{\lambda} + \sum_{i=2}^{3} A_i (x_i^k - x_i^*) \rangle + \beta \langle A_3 (x_3^k - x_3^*), A_2 (x_2^k - x_2^*) \rangle.
\]

(12)

3. The ADMM with Three Blocks

In this section, we first investigate the contractive property of the distance between the sequence generated by ADMM with three blocks and the solution set under the condition that \( 0 < \beta \leq \min \{ \mu_2/\lambda_2, \mu_3/\lambda_2 \}. \)

Lemma 2. Let \( v^* = (x^*_1, x^*_2, x^*_3, \lambda^*) \) be a KKT point of problem (3) and let the sequence \( \{v^k = (x^k_1, x^k_2, x^k_3, \lambda^k)\} \) be generated by the ADMM with three blocks. Then, it holds that

\[
\| u^{k+1} - u^* \|^2 \leq \| u^k - u^* \|^2 - \beta \| A_3 (x_3^{k+1} - x_3^*) \|^2 \\
- \beta \| A_1 x_1^{k+1} + A_2 x_2^{k} + A_3 x_3^{k+1} - b \|^2 \\
- 2 \mu_1 \| x_1^{k+1} - x_1^* \|^2 \\
- 2 \| x_2^{k+1} - x_2^* \|^2 + \frac{\beta}{\mu_2} \| x_2^{k+1} - x_2^* \|^2 \\
- 2 \| x_3^{k+1} - x_3^* \|^2 + \frac{2}{\mu_3} \| x_3^{k+1} - x_3^* \|^2 \\
- \beta \| A_2 (x_2^{k} - x_2^*) \|^2,
\]

(13)

Proof. Since \( x^i \) minimizes \( f_i (\cdot) - \langle A_i^T \lambda_i, \cdot \rangle, \) we deduce from the first order optimality condition that

\[
A^T \lambda^j \in \partial f_j (x^j), \quad j = 0, 1, \ldots, k.
\]

By (14) and the monotonicity of \( \partial f_j (\cdot) \) (11), it is easily seen that

\[
\langle x^j_k - x^j_3, A^T \lambda^j_k - A^T \lambda^j_3 \rangle \geq 0.
\]

Then for each \( k, \)

\[
\langle u^{k+1} - u^*, G (u^{k+1} - u^*) \rangle \\
\geq \sum_{i=1}^{3} \mu_i \| x_i^{k+1} - x_i^* \|^2 + \langle \lambda^k - \lambda^k + A_2 (x_2^{k} - x_2^*) \rangle \\
+ \beta \langle A_3 (x_3^{k+1} - x_3^*), A_2 (x_2^{k+1} - x_2^*) \rangle \\
\geq \sum_{i=1}^{3} \mu_i \| x_i^{k+1} - x_i^* \|^2 + \| x_2^{k+1} - x_2^* \|^2 \mu_2 \| \lambda^k - \lambda^k + A_2 A_3 \| \\
+ \langle \lambda^k - \lambda^k, A_2 (x_2^{k+1} - x_2^*) \rangle \\
+ \beta \langle A_2 (x_2^{k} - x_2^*), x_2^{k+1} - x_2^* \rangle\|^2 \geq \frac{\beta}{4} \| A_2 (x_2^{k} - x_2^*), x_2^{k+1} - x_2^* \|^2,
\]

(16)

where the last “\( \geq \)" follows from the elementary inequality

\[
\langle x, y \rangle \geq -\| x \|^2 - \frac{1}{4} \| y \|^2.
\]

Since

\[
\| A_3 (x_3^{k+1} - x_3^*) \|^2 \leq 2 \| A_3 (x_3^{k+1} - x_3^*) \|^2 \\
+ 2 \| A_3 (x_3^k - x_3^*) \|^2,
\]

(18)

by direct computations, we further obtain that

\[
\| u^{k+1} - u^* \|^2 \geq \| u^{k+1} - u^* \|^2 \\
+ \| u^{k+1} - u^* \|^2_G + 2 \mu_1 \| x_1^{k+1} - x_1^* \|^2 \\
+ 2 \| x_2^{k+1} - x_2^* \|^2 \mu_2 (\beta/2) A_2 A_3 \\
+ 2 \| x_3^{k+1} - x_3^* \|^2 \mu_3 (\beta/2) A_3 A_2 \\
+ 2 \langle \lambda^k - \lambda^k, A_2 (x_2^{k} - x_2^*) \rangle \\
- \beta \| A_2 (x_2^{k} - x_2^*) \|^2 \|^2,
\]

(19)
which, together with $G = M - (\beta A_1^T A_2 \ 0)$, implies
\begin{equation}
\| u^k - u^* \|_M^2 \geq \| u^{k+1} - u^* \|_2^2 \\
+ \| u^{k+1} - u^* \|_M^2 + 2\mu_1 \| x_1^{k+1} - x_1^* \|_2^2 \\
+ 2 \| x_2^{k+1} - x_2^* \|_{\mu_2 I_n - \beta A_1^T A_2}^2 \\
+ 2 \| x_3^{k+1} - x_3^* \|_{\mu_3 I_n - \beta A_1^T A_3}^2 \\
+ 2 \langle \lambda - \lambda^{k+1}, A_2 (x_2^k - x_2^{k+1}) \rangle.
\end{equation}

Note that
\begin{equation}
\| x_2^k - x_2^{k+1} \|_{\beta A_1^T A_2}^2 + 2 \langle \lambda - \lambda^{k+1}, A_2 (x_2^k - x_2^{k+1}) \rangle \\
+ \frac{1}{\beta} \| \lambda - \lambda^{k+1} \|_2^2 \\
= \beta \| A_1 x_1^{k+1} + A_2 x_2^k + A_3 x_3^{k+1} - b \|_2^2.
\end{equation}

We complete the proof of this lemma.

With the above preparation, we are ready to prove the convergence of the ADMM with three blocks for solving (3) given the following conditions.

**Theorem 3.** Let \( \{v^k = (x_1^k, x_2^k, x_3^k, \lambda^k)\} \) be the sequence generated by the ADMM with three blocks. Then \( \{v^k\} \) converges to a KKT point of problem (3) if either of the following conditions holds:

(i) \( \mu_1 > 0 \) and \( 0 < \beta \leq \min\{\mu_2/\|A_2\|_2^2, \mu_3/\|A_3\|_2^2\} \);

(ii) \( A_1 \) is of full column rank, \( 0 < \beta < \mu_2/\|A_2\|_2^2 \), and \( \beta \leq \mu_3/\|A_3\|_2^2 \).

**Proof.** By the inequality (13), it follows that the sequence \( \{A_2 x_2^k, A_3 x_3^k, \lambda^k\} \) is bounded. Recall that
\begin{equation}
A_1 x_1^{k+1} = \frac{\lambda^k - \lambda^{k+1}}{\beta} - A_2 x_2^{k+1} - A_3 x_3^{k+1} + b.
\end{equation}

Hence \( \{A_1 x_1^k\} \) is also bounded. Moreover, from (13) we see immediately that
\begin{equation}
+ \infty > \sum_{k=1}^{\infty} \beta \| A_3 (x_3^{k+1} - x_3^*) \|_2^2 \\
+ \beta \| A_1 x_1^{k+1} + A_2 x_2^k + A_3 x_3^{k+1} - b \|_2^2 \\
+ \sum_{k=1}^{\infty} 2\mu_1 \| x_1^{k+1} - x_1^* \|_2^2 \\
+ \sum_{k=1}^{\infty} \| x_2^{k+1} - x_2^* \|_{\mu_2 I_n - \beta A_1^T A_2}^2 \\
+ \sum_{k=1}^{\infty} \| x_3^{k+1} - x_3^* \|_{\mu_3 I_n - \beta A_1^T A_3}^2.
\end{equation}

According to the condition that \( 0 < \beta \leq \min\{\mu_2/\|A_2\|_2^2, \mu_3/\|A_3\|_2^2\} \), we know
\begin{equation}
\sum_{k=1}^{\infty} \| A_3 (x_3^{k+1} - x_3^*) \|_2^2 < +\infty,
\end{equation}
\begin{equation}
\sum_{k=1}^{\infty} \| A_1 x_1^{k+1} + A_2 x_2^k + A_3 x_3^{k+1} - b \|_2^2 < +\infty,
\end{equation}
\begin{equation}
\sum_{k=1}^{\infty} \| x_2^{k+1} - x_2^* \|_{\mu_2 I_n - \beta A_1^T A_2}^2 < +\infty,
\end{equation}
\begin{equation}
\sum_{k=1}^{\infty} \| x_3^{k+1} - x_3^* \|_{\mu_3 I_n - \beta A_1^T A_3}^2 < +\infty.
\end{equation}

It therefore holds that
\begin{equation}
\lim_{k\to\infty} \| A_3 (x_3^{k+1} - x_3^*) \|_2^2 = 0,
\end{equation}
\begin{equation}
\lim_{k\to\infty} \| A_1 x_1^{k+1} + A_2 x_2^k + A_3 x_3^{k+1} - b \|_2^2 = 0,
\end{equation}
\begin{equation}
\lim_{k\to\infty} \| x_2^{k+1} - x_2^* \|_{\mu_2 I_n - \beta A_1^T A_2}^2 = 0,
\end{equation}
\begin{equation}
\lim_{k\to\infty} \| x_3^{k+1} - x_3^* \|_{\mu_3 I_n - \beta A_1^T A_3}^2 = 0.
\end{equation}

Therefore, the sequence \( \{\mu_1 \| x_1^k \|_2^2, \| x_2^k \|_{\mu_2 I_n - \beta A_1^T A_2}, \| x_3^k \|_{\mu_3 I_n - \beta A_1^T A_3} \} \) is bounded, which, together with the boundedness of \( \{A_1 x_1^k, A_2 x_2^k, A_3 x_3^k, \lambda^k\} \), implies that \( \{x_1^k, x_2^k, \lambda^k\} \) is bounded, and \( \{x_1^k\} \) is bounded given the condition \( \mu_1 > 0 \) or \( A_1 \) is of full column rank. Moreover, since
\begin{equation}
\| x_3^{k+1} - x_3^k \|_2^2 = \| A_3 x_3^{k+1} - A_3 x_3^k \|_2^2 \\
+ \| x_3^{k+1} - x_3^k \|_{\mu_3 I_n - \beta A_1^T A_3},
\end{equation}
by the first equality in (25) and the third equality in (26), it holds that
\begin{equation}
\lim_{k\to\infty} \| x_3^{k+1} - x_3^k \|_2 = 0.
\end{equation}
We proceed to prove the convergence of ADMM by considering the following two cases.

Case 1 ($\mu_1 > 0$ and $\beta \leq \min(\mu_2/\|A_2\|_2^2, \mu_3/\|A_3\|_2^2)$). In this case, the sequence $\{x_1^k\}$ converges to $x_1^*$, and we have

$$\lim_{k \to \infty} \|A_2 x_2^{k+1} - A_2 x_2^k\| = 0, \quad \lim_{k \to \infty} \|\lambda^{k+1} - \lambda^k\| = 0. \tag{29}$$

By the second equality in (26), we deduce from (29) that

$$\lim_{k \to \infty} \|x_2^{k+1} - x_2^k\| = 0. \tag{30}$$

Since $\{x_2^k, x_2^\infty, \lambda^\infty\}$ is bounded, there exist a triple $(x_2^{\infty}, x_2^{\infty}, \lambda^{\infty})$ and a subsequence $\{n_k\}$ such that

$$\lim_{k \to \infty} x_2^{n_k} = x_2^{\infty}, \quad \lim_{k \to \infty} x_2^{n_k} = x_2^{\infty}, \quad \lim_{k \to \infty} \lambda^{n_k} = \lambda^{\infty}. \tag{31}$$

which by combining (25), (29) with given conditions, implies

$$\lim_{k \to \infty} x_2^{n_k+1} = x_2^{\infty}, \quad \lim_{k \to \infty} x_2^{n_k+1} = x_2^{\infty}, \quad \lim_{k \to \infty} \lambda^{n_k+1} = \lambda^{\infty}. \tag{32}$$

Note that

$$0 \in \partial f_1 (x_1^{k+1}) - A_1^T \lambda^{k+1} + A_1 A_2 (x_2^k - x_2^{k+1}) + A_1^T A_3 (x_3^k - x_3^{k+1}) \tag{33}$$

and

$$0 \in \partial f_2 (x_2^{k+1}) - A_2^T \lambda^{k+1} + A_2 A_3 (x_3^k - x_3^{k+1}), \quad 0 \in \partial f_3 (x_3^{k+1}) - A_3^T \lambda^{k+1}, \quad \lambda^{k+1} = \lambda^k - \beta (A_1 x_1^{k+1} + A_2 x_2^{k+1} + A_3 x_3^{k+1}).$$

Then, by taking the limits on both sides of (33), using (25) and (29), and invoking the upper semicontinuous of $\partial f_1 (\cdot), \partial f_2 (\cdot)$, and $\partial f_3 (\cdot)$ [24], one can immediately write

$$0 \in \partial f_1 (x^*) - A_1^T \lambda^{\infty}, \quad 0 \in \partial f_2 (x_2^{\infty}) - A_2^T \lambda^{\infty}, \quad 0 \in \partial f_3 (x_3^{\infty}) - A_3^T \lambda^{\infty}, \quad A_1 x^* + A_2 x_2^{\infty} + A_3 x_3^{\infty} = b,$$

which indicates $(x_1^*, x_2^{\infty}, x_3^{\infty}, \lambda^{\infty})$ is a KKT point of problem (3). Hence, the inequality (13) is also valid if $(x_1^*, x_2^{\infty}, x_3^{\infty}, \lambda^{\infty})$ is replaced by $(x_1^*, x_2^{\infty}, x_3^{\infty}, \lambda^{\infty})$. Then it holds that

$$2\beta \|A_2 x_2^{k+1} - A_2 x_2^k\|^2 + \beta \|A_3 x_3^{k+1} - A_3 x_3^{\infty}\|^2 \tag{35}$$

which yields

$$\lim_{k \to \infty} \|x_2^k - x_2^{\infty}\|^2_{A_2^T A_2} = 0, \quad \lim_{k \to \infty} \|x_3^k - x_3^{\infty}\|^2_{A_3^T A_3} = 0, \quad \lim_{k \to \infty} \|\lambda^k - \lambda^{\infty}\| = 0. \tag{36}$$

By adding the last two equalities in (26) to (36), we know

$$\lim_{k \to \infty} x_2^k = x_2^{\infty}, \quad \lim_{k \to \infty} x_3^k = x_3^{\infty}. \tag{37}$$

Therefore, we have shown that the whole sequence $\{(x_1^k, x_2^k, x_3^k, \lambda^k)\}$ converges to $(x_1^*, x_2^{\infty}, x_3^{\infty}, \lambda^{\infty})$ under condition (i) in Theorem 3.

Case 2 ($A_1$ has full column rank, $0 < \beta < \mu_2/\|A_2\|_2^2$ and $\beta \leq \mu_3/\|A_3\|_2^2$). In this case, the sequence $\{x_2^k\}$ converges to $x_2^*$ and $\{x_1^k\}$ is bounded. From the second equality in (25) and (28), we have

$$\lim_{k \to \infty} \|A_1 x_1^{k+1} - A_1 x_1^k\| = 0, \quad \lim_{k \to \infty} \|\lambda^k - \lambda^{k+1}\| = 0. \tag{39}$$

Since $A_1$ is of full column rank, it therefore holds that

$$\lim_{k \to \infty} \|x_1^{k+1} - x_1^k\| = 0. \tag{40}$$

Let $(x_1^{\infty}, x_2^{\infty}, x_3^{\infty}, \lambda^{\infty})$ be a cluster point of the sequence $\{(x_1^k, x_2^k, x_3^k, \lambda^k)\}$. Following a similar proof in Case 1, we are able to show $(x_1^{\infty}, x_2^*, x_3^{\infty}, \lambda^{\infty})$ is a KKT point of problem (3) and the whole sequence $\{(x_1^k, x_2^k, x_3^k, \lambda^k)\}$ converges to this point.

**Remark 4** (see [22]). The authors proved the convergence of the ADMM under the conditions that $f_1, f_2$, and $f_3$ are strongly convex and $0 < \beta < \min\{1, \mu_2/\|A_2\|_2^2\}$. Our result improves the upper bound $\min\{1, \mu_2/\|A_2\|_2^2\}$ by $\min\{\mu_2/\|A_2\|_2^2, \mu_3/\|A_3\|_2^2\}$. Moreover, in our condition (ii), the strongly convexity assumption is only imposed on $f_2$ and $f_3$ while $f_1$ is not necessarily strongly convex with positive modulus.

### 4. The Relaxed ADMM with Three Blocks

For the ADMM with two blocks, Ye and Yuan [25] developed a variant of alternating direction method with an optimal step size. Numerical results demonstrated that an additional computation on the optimal step size would improve the efficiency of the new variant of ADMM. In this section, by adopting the essential idea of Ye and Yuan [25], we propose...
a relaxed ADMM with three blocks to accelerate the ADMM via an optimal step size. For notational simplicity, we write

\[ \Phi(u^k, \bar{u}^k) := \frac{3\beta}{4} \left\| A_2 \left( x_2^k - \bar{x}_2^k \right) \right\|^2 + \beta \left\| A_3 \left( x_3^k - \bar{x}_3^k \right) \right\|^2 \]

with

\[ + \frac{1}{\beta} \left\| \lambda^k - \bar{\lambda}^k \right\|^2 + \left\langle \lambda^k - \bar{\lambda}^k, A_2 \left( x_2^k - \bar{x}_2^k \right) + A_3 \left( x_3^k - \bar{x}_3^k \right) \right\rangle \]

where the second inequality follows Cauchy inequality. It therefore holds that

\[ \Phi(u^k, \bar{u}^k) \geq \frac{1}{6} \left\| u^k - \bar{u}^k \right\|_{G'}^2 \]  

which completes the proof of the first part. By Lemma 1 and the elementary inequality (17), it can be easily verified that

\[ \left\langle u^k - u^*, G \left( u^k - u^* \right) \right\rangle \]

\[ \geq \Phi(u^k, \bar{u}^k) + \mu_1 \left\| x_1^k - x_1^* \right\|^2 + \mu_2 \left\| x_2^k - x_2^* \right\|^2 + \left\| x_3^k - x_3^* \right\|^2_{\mu_3 I_{n_3} - \beta A_A^T A_A} \]

and then

\[ \left\| u^{k+1} - u^* \right\|_G^2 \leq \left( 1 - (1/36) \gamma (2 - \gamma) (\alpha^*)^2 \right) \left\| u^k - u^* \right\|_G^2 \]

\[ - 2\mu_2 \alpha^* \left\| x_2^k - x_2^* \right\|_{\mu_3 I_{n_3} - \beta A_A^T A_A}^2 \]

This, together with the fact that \( \alpha^* \geq 1/6 \), completes the proof.

Based on the above inequality, we are able to prove the following convergence result of the relaxed ADMM with three blocks. Since the proof is in line with that of Theorem 3, we omit it.

**Theorem 6.** Let \( \{v^k\} = (x_1^k, x_2^k, x_3^k, \lambda^k) \) be the sequence generated by the relaxed ADMM. Then \( \{v^k\} \) converges to a KKT point of problem (3) under the conditions that \( 0 < \beta \leq \mu_3 \left\| A_3 \right\|^2 \) and \( A_1, A_2, \) and \( A_3 \) are of full column rank.

## 5. Conclusion Remarks

In this paper, we take a step to investigate the ADMM for separable convex programming problems with three blocks. Based on the contractive analysis of the distance between the sequence and the solution set, we establish theoretical results to guarantee the global convergence of ADMM with three blocks under weaker conditions than those employed in [22]. By adopting the essential idea of [25], we also present a relaxed ADMM with an optimal step size to accelerate the ADMM and prove its convergence under mild assumptions.

1. Introduction

Let $H$ be a real Hilbert space with inner product $\langle \cdot, \cdot \rangle$ and norm $\| \cdot \|$, let $K$ be a nonempty closed convex subset of $H$, and let $F : H \rightarrow H$ be an operator. Then the variational inequality problem $\text{VI}(F, K)$ \cite{1} is to find $x^* \in K$ such that

$$x^* \in K, \quad \langle x - x^*, F(x^*) \rangle \geq 0, \quad \forall x \in K. \quad (1)$$

The literature contains many methods for solving variational inequality problems; see \cite{2–25} and references therein. According to the relationship between the variational inequality problems and a fixed point problem, we can obtain

$$x^* \text{ is the solution of } \text{VI}(F, K) \iff x^* = P_K \left[ x^* - \beta F(x^*) \right], \quad \beta > 0, \quad (2)$$

where the projection operator $P_K$ is the projection from $H$ onto $K$, that is,

$$P_K(x) = \arg\min_{y \in K} \|x - y\|, \quad \forall x \in H. \quad (3)$$

In this paper, $F : H \rightarrow H$ is an operator with $F : \kappa$-Lipschitz and $\eta$-strongly monotone; that is, $F$ satisfies the following conditions:

$$\|F(x) - F(y)\| \leq \kappa \|x - y\|,$$

$$\langle F(x) - F(y), x - y \rangle \geq \eta \|x - y\|^2, \quad \forall x, y \in K. \quad (4)$$

If $\beta$ is small enough, then $P_K$ is a contraction. Naturally, the convergence of Picard iterates generated by the right-hand side of (2) is obtained by Banach’s fixed point theorem. Such a method is called the projection method or more results about the projection method see \cite{6, 8, 20} and so forth.

In fact, the projection $P_K$ in the contraction methods may not be easy to compute, and a great effort is to compute the projection $P_K$ in each iteration. Yamada and Deutsch have provided a hybrid steepest-descent method for solving $\text{VI}(F, K)$ \cite{2, 3} in order to reduce the difficulty and complexity of computing the projection $P_K$. Subsequently, the convergence of hybrid steepest-descent methods was given out by Xu and Kim \cite{4} and Zeng et al. \cite{5}. Naturally, by analyzing several three-step iterative methods in each iteration by the fixed pointed equation, we can obtain the Noor iterations. Recently, Ding et al. \cite{7} proposed a three-step relaxed hybrid steepest-descent method for variational
inequalities, and the simple proof of three-step relaxed hybrid steepest-descent methods under different conditions was introduced by Yao et al. [24]. The literature [14, 16] described a modified and relaxed hybrid steepest-descent (MRHSD) method and the different convergence of the MRHSD method under different conditions. A set of practical numerical experiments in the literature [16] demonstrated that the MRHSD method has different efficiency under different conditions. Subsequently, the prediction-correction and relaxed hybrid steepest-descent method (PRH method) [15] makes more use of the history information and less decreases the loss of information than the methods [7, 14]. The PRH method introduced more descent directions than the MRHSD method [14, 16], and computing these descent directions only needs the history information.

In this paper, we will prove the strong convergence of PRH method under different and suitable restrictions imposed on parameters (Condition 12), which differs from that of [15]. Moreover, the proof of strong convergence is different from the previous proof in [15], which is not similar to that in [7] in Step 2. And more importantly, numerical experiments verify that the PRH method under Condition 12 is more efficient than that under Condition 10, and the PRH method under some descent directions is more slightly efficient than that of the MRHSD method [14, 16]. Furthermore, it is easy to obtain these descent directions.

The remainder of the paper is organized as follows. In Section 2, we review several lemmas and preliminaries. We prove the convergence theorem under Condition 12 in Section 3. In Section 4, we give out a series of numerical experiments, which demonstrated that the PRH method under Condition 12 is more efficient than under Condition 10. Section 5 concludes the paper.

2. Preliminaries

In order to proof the later convergence theorem, we introduce several lemmas and the main results in the following.

**Lemma 1.** In a real Hilbert space $H$, there holds the inequality

$$\|x + y\|^2 \leq \|x\|^2 + 2 \langle y, x + y \rangle, \quad \forall x, y \in H. \tag{5}$$

The lemma is a basic result of a Hilbert space with the inner product.

**Lemma 2 (demiclosedness principle).** Assume that $T$ is a nonexpansive self-mapping on a nonempty closed convex subset $K$ of a Hilbert space $H$. If $T$ has a fixed point, then $(I - T)$ is demiclosed. That is, whenever $x_n$ is a sequence in $K$ weakly converging to some $x \in K$ and the sequence $(I - T)x_n$ strongly converges to some $y \in H$, it follows that $(I - T)x = y$. Here $I$ is the identity operator of $H$.

The following lemma is an immediate result of a projection mapping onto a closed convex subset of a Hilbert space.

**Lemma 3.** Let $K$ be a nonempty closed convex subset of $H$. For all $x, y \in H$ and $z \in K$, then

1. $\langle P_K(x) - x, z - P_K(y) \rangle \geq 0$,
2. $\|P_K(x) - P_K(y)\|^2 \leq 2\|x - y\|^2 - \|P_K(x) - x + y - P_K(y)\|^2$.

**Lemma 4 (see [13]).** Let $\{x_n\}$ and $\{y_n\}$ be bounded sequence in a Banach space $X$ and let $\{\zeta_n\}$ be a sequence in $[0, 1]$ with $0 < \liminf_{n \to \infty} \zeta_n \leq \limsup_{n \to \infty} \zeta_n < 1$. Suppose $x_{n+1} = (1 - \zeta_n)x_n + \zeta_n y_n$ for all integers $n \geq 0$ and $\limsup_{n \to \infty} (\|y_{n+1} - y_n\| - \|x_{n+1} - x_n\|) \leq 0$. Then $\limsup_{n \to \infty} \|x_n - x\| = 0$.

**Lemma 5 ([5, 7]).** Let $\{s_n\}$ be a sequence of nonnegative real numbers satisfying the inequality

$$s_{n+1} \leq (1 - \alpha_n) s_n + \alpha_n \tau_n + \gamma_n, \quad \forall n \geq 0, \tag{6}$$

where $\alpha_n$, $\tau_n$ and $\gamma_n$ satisfy the following conditions:

1. $\alpha_n \in [0, 1]$, $\sum_{n=0}^{\infty} \alpha_n = \infty$, or $\prod_{n=0}^{\infty} (1 - \alpha_n) = 0$,
2. $\lim_{n \to \infty} \sup \tau_n = 0,$
3. $\gamma_n \in [0, \infty)$, $\sum_{n=0}^{\infty} \gamma_n < \infty$.

Then $\lim_{n \to \infty} s_n = 0$.

Since $F$ is $\eta$-strongly monotone, $VI(F, K)$ has a unique solution $x^* \in K$ [5]. Assume that $T : H \to H$ is a nonexpansive mapping with the fixed point set $\text{Fix}(T) = K$. Obviously $\text{Fix}(P_K) = K$.

For any given numbers $\lambda \in (0, 1)$ and $\mu \in (0, 2\eta/\kappa^2)$, we define the mapping $T_\mu^\lambda : H \to H$ by

$$T_\mu^\lambda x : = Tx - \lambda \mu F(Tx), \quad \forall x \in H. \tag{7}$$

**Lemma 6 (see [5]).** If $0 < \mu < 2\eta/\kappa^2$ and $0 < \lambda < 1$, then $T_\mu^\lambda$ is a contraction. In fact,

$$\|T_\mu^\lambda x - T_\mu^\lambda y\| \leq (1 - \lambda \delta) \|x - y\|, \tag{8}$$

where $\delta = 1 - \sqrt{1 - \mu (2\eta - \mu \kappa^2)}$, for all $x, y \in H$.

**Lemma 7 (see [7]).** Let $\{\alpha_n\}$ be a sequence of nonnegative numbers with $\limsup_{n \to \infty} \alpha_n < \infty$ and let $\{\beta_n\}$ be sequence of real numbers with $\limsup_{n \to \infty} \beta_n < \infty$. Then

$$\limsup_{n \to \infty} \beta_n \leq 0. \tag{9}$$

3. Convergence Theorem

Before analyzing the convergence theorem, we first review the PRH method and related results [15].

**Algorithm 8 (see [15]).** Take three fixed numbers $t, \rho, \gamma \in (0, 2\eta/\kappa^2)$, starting with arbitrarily chosen initial points $x_0 \in H$, compute the sequences $\{x_n\}$, $\{x_\ast_n\}$, $\{x_{\ast\ast}_n\}$, $\{x_{\ast\ast\ast}_n\}$ such that;

- **Prediction**

  Step 1: $\tilde{x}_n = \gamma \rho x_n + (1 - \gamma \rho)[T x_n - \lambda \mu \eta F(T x_n)]$,
  Step 2: $\hat{x}_n = \beta \rho x_n + (1 - \beta \rho)[T x_n - \lambda \mu \eta F(T x_n)]$,
  Step 3: $\check{x}_n = \theta \rho x_n + (1 - \theta \rho)x_n, 0 \leq \theta \rho \leq 1,$
Correction

Step 4: \( x_{n+1} = \alpha_n \overline{x}_n + (1 - \alpha_n)[T \overline{x}_n - \lambda_{n+1} F(T \overline{x}_n)] \),

where \( T' : H \to H \) is a nonexpansive mapping.

Let \( \{\alpha_n\} \subset (0, 1), \{\beta_n\} \subset (0, 1] \) and \( \{\gamma_n\} \subset (0, 1], \{\lambda_n\}, \{\lambda_n'\}, \{\lambda_n''\} \subset (0, 1) \) satisfy the following conditions.

Remark 9. In fact, the PRH method is the MRHSD method when \( \theta_n = 0 \), for all \( n \).

Condition 10. One has

\[
\sum_{n=1}^{\infty} |\alpha_n - \alpha_{n-1}| < \infty, \quad \sum_{n=1}^{\infty} |\beta_n - \beta_{n-1}| < \infty,
\]

\[
\sum_{n=1}^{\infty} |\gamma_n - \gamma_{n-1}| < \infty, \quad \sum_{n=1}^{\infty} |\lambda_n - \lambda_{n-1}| = \infty,
\]

\[
\lim_{n \to \infty} \alpha_n = 0, \quad \lim_{n \to \infty} \beta_n = 1, \quad \lim_{n \to \infty} \gamma_n = 1,
\]

\[
\lim_{n \to \infty} \lambda_n = 0, \quad \sum_{n=1}^{\infty} \lambda_n = \infty,
\]

\[
\lambda_n \geq \max \{\lambda_n', \lambda_n''\}, \quad \forall n \geq 1.
\]

Theorem 11 (see [15]). In Condition 10, the sequence \( \{x_n\} \) converges strongly to \( x^* \in K \), and \( x^* \) is the unique solution of the VI(\( F, K \)).

We obtain the strong convergence theorem of PRH method for variational inequalities under different assumptions.

Condition 12. One has

\[
0 < \lim_{n \to \infty} \inf \alpha_n \leq \lim_{n \to \infty} \sup \alpha_n < 1,
\]

\[
\lim_{n \to \infty} \beta_n = 1, \quad \lim_{n \to \infty} \gamma_n = 1,
\]

\[
\lim_{n \to \infty} \lambda_n = 0, \quad \sum_{n=1}^{\infty} \lambda_n = \infty,
\]

\[
\lambda_n \geq \max \{\lambda_n', \lambda_n''\}, \quad \forall n \geq 1.
\]

Theorem 13. The sequence \( \{x_n\} \) converges strongly to \( x^* \in K \), and \( x^* \) is the unique solution of the VI(\( F, K \)). Assume that \( \{\alpha_n\}, \{\beta_n\} \) and \( \{\gamma_n\}, \{\lambda_n\}, \{\lambda_n'\}, \{\lambda_n''\} \) satisfy Condition 12.

Proof. We divide the proof into several steps.

Step 1. \( \{x_n\}, \{\overline{x}_n\}, \{\overline{x}_n\}, \) and \( \{\overline{x}_n\} \) are bounded. Since \( F \) is \( \eta \)-strongly monotone, VI(\( F, K \)) has a unique solution \( x^* \in K \), and \( T^{\lambda_n}_{\nu(\xi)} x = x^* - \lambda_n F(x^*), T^{\lambda_n}_{\nu(\xi)} x = x^* - \lambda_n F(x^*), T^{\lambda_n}_{\nu(\xi)} x = x^* - \lambda_n F(x^*). \)

A series of computations yields

\[
\|x_{n+1} - x^*\| = \|\alpha_n \overline{x}_n + (1 - \alpha_n) T^{\lambda_n}_{\nu(\xi)} \overline{x}_n - x^*\|
\]

\[
\leq \alpha_n \|\overline{x}_n - x^*\| + (1 - \alpha_n) \|T^{\lambda_n}_{\nu(\xi)} \overline{x}_n - x^*\|
\]

\[
\leq \alpha_n \|\overline{x}_n - x^*\| + (1 - \alpha_n) \left[\|T^{\lambda_n}_{\nu(\xi)} \overline{x}_n - T^{\lambda_n}_{\nu(\xi)} x^*\| + \|T^{\lambda_n}_{\nu(\xi)} x^* - x^*\|\right]
\]

\[
\leq \alpha_n \|\overline{x}_n - x^*\| + (1 - \alpha_n) \left[(1 - \lambda_n \tau) \|\overline{x}_n - x^*\| + \lambda_n \|F(x^*)\|\right],
\]

(12)

where \( \tau = 1 - \sqrt{1 - t(2\eta - t\kappa^2)} \in (0, 1) \).

Moreover, we also obtain

\[
\|\overline{x}_n - x^*\| = \|\beta_n x_n + (1 - \beta_n) T^{\lambda_n'}_{\nu(\xi)} \overline{x}_n - x^*\|
\]

\[
\leq \beta_n \|x_n - x^*\| + (1 - \beta_n) \|T^{\lambda_n'}_{\nu(\xi)} \overline{x}_n - x^*\|
\]

\[
\leq \beta_n \|x_n - x^*\| + (1 - \beta_n) \left[\|T^{\lambda_n'}_{\nu(\xi)} \overline{x}_n - T^{\lambda_n'}_{\nu(\xi)} x^*\| + \|T^{\lambda_n'}_{\nu(\xi)} x^* - x^*\|\right]
\]

\[
\leq \beta_n \|x_n - x^*\| + (1 - \beta_n) \left[(1 - \lambda_n \tau) \|\overline{x}_n - x^*\| + \lambda_n \|F(x^*)\|\right]
\]

\[
\leq \beta_n \|x_n - x^*\| + (1 - \beta_n) \|x_n - x^*\| + (1 - \beta_n) \|\overline{x}_n - x^*\|
\]

\[
\leq \beta_n \|x_n - x^*\| + (1 - \beta_n) \lambda_n \|F(x^*)\|,
\]

(13)

where \( \tau' = 1 - \sqrt{1 - \rho(2\eta - t\kappa^2)} \in (0, 1) \).

Moreover, we also obtain

\[
\|x_n - x^*\| = \|\gamma_n x_n + (1 - \gamma_n) T^{\lambda_n''}_{\nu(\xi)} x_n - x^*\|
\]

\[
\leq \gamma_n \|x_n - x^*\| + (1 - \gamma_n) \|T^{\lambda_n''}_{\nu(\xi)} x_n - x^*\|
\]

\[
\leq \gamma_n \|x_n - x^*\| + (1 - \gamma_n) \left[\|T^{\lambda_n''}_{\nu(\xi)} x_n - T^{\lambda_n''}_{\nu(\xi)} x^*\| + \|T^{\lambda_n''}_{\nu(\xi)} x^* - x^*\|\right]
\]

\[
\leq \gamma_n \|x_n - x^*\| + (1 - \gamma_n) \left[(1 - \lambda_n \tau') \|x_n - x^*\| + \lambda_n' \|F(x^*)\|\right]
\]

\[
\leq \gamma_n \|x_n - x^*\| + (1 - \gamma_n) \|x_n - x^*\| + (1 - \gamma_n) \lambda_n' \|F(x^*)\|,
\]

(14)
where \( \tau'' = 1 - \sqrt{1 - \gamma(2\eta - \xi^2)} \in (0, 1) \), substituting (14) into (13) and (14) into (12), we immediately obtain

\[
\|\tilde{x}_n - x^*\| = \beta_n \|x_n - x^*\| + (1 - \beta_n) \\
\times \left[ (1 - \lambda_{n+1}^{(i)} \tau') \|\tilde{x}_n - x^*\| + \lambda_{n+1}^{(i)} \rho \|F(x^*)\| \right] \\
\leq \beta_n \|x_n - x^*\| + (1 - \beta_n) \\
\times \left[ (1 - \lambda^{(i)}_{n+1} \tau') \|x_n - x^*\| \\
+ (1 - \gamma_n) \lambda_{n+1}'' \|F(x^*)\| + \lambda_{n+1}^{(i)} \rho \|F(x^*)\| \right] \\
\leq \|x_n - x^*\| + (1 - \beta_n) \lambda_{n+1} (y + \rho) \|F(x^*)\|. \\
(15)
\]

Furthermore,

\[
\|\tilde{x}_n - x^*\| = \|\theta_n \tilde{x}_n + (1 - \theta_n) \tilde{x}_n - x^*\| \\
\leq \theta_n \|\tilde{x}_n - x^*\| + (1 - \theta_n) \|\tilde{x}_n - x^*\| \\
\leq \theta_n \|x_n - x^*\| + (1 - \theta_n) \|x_n - x^*\| \\
\times [ (1 - \lambda_{n+1}^{(i)} \tau') \|\tilde{x}_n - x^*\| + \lambda_{n+1}^{(i)} \rho \|F(x^*)\| ] \\
\leq \alpha_n \|\tilde{x}_n - x^*\| + (1 - \alpha_n) \\
\times \left[ (1 - \lambda_{n+1}^{(i)} \tau) \|\tilde{x}_n - x^*\| + \lambda_{n+1}^{(i)} \rho \|F(x^*)\| \right] \\
\leq \alpha_n \|x_n - x^*\| + (1 - \gamma_n) \lambda_{n+1}'' \|F(x^*)\| \\
\times (1 - \beta_n) \lambda_{n+1} (y + \rho) \|F(x^*)\| \\
\times \|\tilde{x}_n - x^*\| + (1 - \beta_n) \lambda_{n+1} (y + \rho) \|F(x^*)\| \\
+ (1 - \gamma_n) \lambda_{n+1}'' \|F(x^*)\| \\
+ \lambda_{n+1}^{(i)} \rho \|F(x^*)\|] \\
\leq \alpha_n \|x_n - x^*\| + \alpha_n (1 - \gamma_n) \lambda_{n+1}'' \|F(x^*)\| + (1 - \alpha_n) \\
\times \left[ (1 - \lambda_{n+1}^{(i)} \tau) \|x_n - x^*\| + \lambda_{n+1} (2 \gamma \rho + \rho) \|F(x^*)\| \right]. \\
(16)
\]

It is easy to obtain the following by induction:

\[
\|x_n - x^*\| \leq M_0, \quad \forall n \geq 0, \\
(17)
\]

where \( M_0 = \max \{3 \|x_0 - x^*\|, 3(\rho + y + t) \|F(x^*)\| / \tau \}, \)

\[
\|\tilde{x}_n - x^*\| \leq \|x_n - x^*\| + (1 - \beta_n) \lambda_{n+1} (y + \rho) \|F(x^*)\| \\
\leq \left(1 + \frac{\tau}{3}\right) M_0,
\]

\[
\|\tilde{x}_n - x^*\| \leq \|x_n - x^*\| + (1 - \gamma_n) \lambda_{n+1}'' \|F(x^*)\| \\
\leq \left(1 + \frac{\tau}{3}\right) M_0,
\]

\[
\|\tilde{x}_n - x^*\| \leq \beta_n \|\tilde{x}_n - x^*\| + (1 - \theta_n) \|\tilde{x}_n - x^*\| \\
\leq 2 \left(1 + \frac{\tau}{3}\right) M_0. \\
(18)
\]

Hence

\[
\{T_{x_n}\}, \{T_{\tilde{x}_n}\}, \{T_{\tilde{x}_n}\}, \\
\{F(T_{x_n})\}, \{F(T_{\tilde{x}_n})\}, \{F(T_{\tilde{x}_n})\}, \{F(T_{\tilde{x}_n})\}
\]

are also bounded.

**Step 2.** Consider \( \|x_{n+1} - x_n\| \to 0 \).

Indeed, by a series of computations, we have

\[
\|\tilde{x}_n - \tilde{x}_{n-1}\| \\
= \|\gamma_n x_n - x_{n-1} + (1 - \gamma_n) T_{\beta_n \gamma_{n-1}}' x_n \\
- (1 - \gamma_n) T_{\beta_n \gamma_{n-1}}'' x_{n-1}\| \\
\leq \|\gamma_n x_n - x_{n-1}\| \\
+ \|(1 - \gamma_n) T_{\beta_n \gamma_{n-1}}'' x_n - (1 - \gamma_n) T_{\beta_n \gamma_{n-1}}'' x_{n-1}\| \\
\leq \|x_n - x_{n-1}\| + \|(1 - \gamma_n) \lambda_{n+1}'' - (1 - \gamma_n) \lambda_n'\| \\
\times \gamma \|F(T_{x_{n-1}})\| \\
+ |\gamma_n - \gamma_{n-1}| (\|x_n\| + \|T_{x_{n-1}}\|).
\]

According to (20) and the prediction step of Algorithm 8, we also obtain

\[
\|\tilde{x}_n - \tilde{x}_{n-1}\| \\
= \|\beta_n x_n - x_{n-1} + (1 - \beta_n) T_{\beta_n \gamma_{n-1}}' x_n \\
- (1 - \beta_n) T_{\beta_n \gamma_{n-1}}'' x_{n-1}\| \\
\leq \|\beta_n x_n - x_{n-1}\| \\
+ \|(1 - \beta_n) T_{\beta_n \gamma_{n-1}}'' x_n - (1 - \beta_n) T_{\beta_n \gamma_{n-1}}'' x_{n-1}\|.
\]
\[ \leq \|x_n - x_{n-1}\| + \left| (1 - \beta_n) \lambda_{n+1}' - (1 - \beta_{n-1}) \lambda_n' \right| \]
\[ \times \rho \|F(T \bar{x}_{n-1})\| + (1 - \beta_n) \left( \lambda_{n+1}' \right) \]
\[ \times |y_n - y_{n-1}| (\|x_{n-1}\| + \|T x_{n-1}\|) \]
\[ + (1 - \beta_n) \left( 1 - \lambda_{n+1}' \right) \left[ (1 - y_n) \lambda_{n+1}' - y_{n-1} \lambda_n' \right] \]
\[ \times \|x_{n-1}\| + \|T \bar{x}_{n-1}\| + \|T \bar{x}_{n-1}\|. \]

(21)

Also by the prediction step of Algorithm 8 and (20), (21), we have

\[ \|\tilde{x}_n - \bar{x}_{n-1}\| \leq \theta_n \|\bar{x}_n - \bar{x}_{n-1}\| + (1 - \theta_n) \|\bar{x}_n - \bar{x}_{n-1}\| \]
\[ \leq \|x_n - x_{n-1}\| \]
\[ + \left| (1 - y_n) \lambda_{n+1}'' - (1 - y_{n-1}) \lambda_n'' \right| \gamma \|F(T x_{n-1})\| \]
\[ + |y_n - y_{n-1}| (\|x_{n-1}\| + \|T x_{n-1}\|) \]
\[ + (1 - \beta_n) \left( 1 - \lambda_n'' \right) |y_n - y_{n-1}| \]
\[ \times (\|x_{n-1}\| + \|T x_{n-1}\|) + (1 - \beta_n) \left( 1 - \lambda_n'' \right) \rho \|F(T x_{n-1})\| \]
\[ + (1 - \beta_n) \left( 1 - \lambda_n'' \right) |y_n - y_{n-1}| \]
\[ \times (\|x_{n-1}\| + \|T x_{n-1}\| + \|T \bar{x}_{n-1}\|). \]

(22)

Let

\[ \tilde{y}_n = T_{\lambda_{n+1}; \bar{x}_n} = T \bar{x}_n - \lambda_{n+1} t F(T \bar{x}_n), \]

so we get

\[ x_{n+1} = \alpha_n \bar{x}_n + (1 - \alpha_n) \tilde{y}_n. \]

(23)

Furthermore,

\[ \|\tilde{y}_n - \tilde{y}_{n-1}\| \]
\[ = \|T \bar{x}_n - T \bar{x}_{n-1} + \lambda_n t F(T \bar{x}_{n-1}) - \lambda_{n+1} t F(T \bar{x}_n)\| \]
\[ \leq \|T \bar{x}_n - T \bar{x}_{n-1}\| + \lambda_n t \|F(T \bar{x}_{n-1})\| \]
\[ + \lambda_{n+1} t \|F(T \bar{x}_n)\| \]
\[ \leq \|\bar{x}_n - \bar{x}_{n-1}\| + \lambda_n t \|F(T \bar{x}_{n-1})\| \]
\[ + \lambda_{n+1} t \|F(T \bar{x}_n)\|. \]

(24)

Apply \( \lim_{n \to \infty} \beta_n = 1 \), \( \lim_{n \to \infty} \lambda_n = 0 \), and \( \lim_{n \to \infty} y_n = 1 \)

and (22), (25) to get

\[ \|\tilde{y}_n - \tilde{y}_{n-1}\| \leq \left| (1 - y_n) \lambda_{n+1}'' - (1 - y_{n-1}) \lambda_n'' \right| \gamma \|F(T x_{n-1})\| \]
\[ + |y_n - y_{n-1}| (\|x_{n-1}\| + \|T x_{n-1}\|) \]
\[ + (1 - \beta_n) \left( 1 - \lambda_n'' \right) \rho \|F(T \bar{x}_{n-1})\| \]
\[ + (1 - \beta_n) \left( 1 - \lambda_n'' \right) |y_n - y_{n-1}| (\|x_{n-1}\| + \|T x_{n-1}\|) \]
\[ + (1 - \beta_n) \left( 1 - \lambda_n'' \right) |y_n - y_{n-1}| (\|x_{n-1}\| + \|T x_{n-1}\| + \|T \bar{x}_{n-1}\|). \]

(26)

According to Lemma 4, we obtain

\[ \lim_{n \to \infty} \|\tilde{y}_{n-1} - x_{n-1}\| = 0. \]

(27)

Furthermore, by \( \lim_{n \to \infty} y_n = 1 \), we also get

\[ \|\bar{x}_n - x_{n}\| \]
\[ = \| - (1 - y_n) x_n + (1 - y_n) \left[ T x_n - \lambda_n' y F(T x_n) \right] \|
\[ \leq (1 - y_n) \|x_n\| + (1 - y_n) \|T x_n\| + \lambda_n' \gamma \|F(T x_n)\| \longrightarrow 0. \]

(28)

By (27), (28) and the correction step of Algorithm 8, we immediately conclude that

\[ \|x_n - x_{n-1}\| \]
\[ = \|\alpha_{n-1} \bar{x}_{n-1} + (1 - \alpha_{n-1}) \tilde{y}_{n-1} - x_{n-1}\| \]
\[ \leq \alpha_{n-1} \|\bar{x}_{n-1} - x_{n-1}\| + (1 - \alpha_{n-1}) \|\tilde{y}_{n-1} - x_{n-1}\| \longrightarrow 0, \]

(29)

so we get

\[ \|x_{n+1} - x_n\| \longrightarrow 0. \]

(30)

**Step 3.** Consider \( \|x_{n+1} - T x_n\| \longrightarrow 0. \)

Indeed, by the prediction step of Algorithm 8, we have

\[ \|\bar{x}_n - x_n\| \]
\[ = \| - (1 - \beta_n) x_n + (1 - \beta_n) \left[ T \bar{x}_n - \lambda_n' \rho F(T \bar{x}_n) \right] \|
\[ \leq (1 - \beta_n) \|x_n\| + (1 - \beta_n) \|T \bar{x}_n\| + \lambda_n' \rho \|F(T \bar{x}_n)\|. \]

(31)

According to the assumption \( \lim_{n \to \infty} \beta_n = 1 \) and \( \lim_{n \to \infty} \lambda_n = 0 \), then

\[ \|\bar{x}_n - x_n\| \longrightarrow 0. \]

(32)
By (32), we immediately obtain
\[ \|\tilde{x}_n - x_n\| \leq \theta_n \|\tilde{x}_n - x_n\| + (1 - \theta_n) \|\tilde{x}_n - x_n\| \rightarrow 0. \] (33)

By a series of computations, we can get
\[ \|x_{n+1} - Tx_n\| = \|\alpha_n (\tilde{x}_n - Tx_n) + (1 - \alpha_n) (T_{t_n}^{\lambda_n} \tilde{x} - Tx_n)\| \leq \alpha_n \|\tilde{x}_n - Tx_n\| + (1 - \alpha_n) \|T\tilde{x}_n - T x_n\| + (1 - \alpha_n) \lambda_{n+1} \|F(T\tilde{x}_n)\| \leq \alpha_n \|\tilde{x}_n - x_n\| + \|\tilde{x}_n - x_n\| + \lambda_{n+1} \|F(T\tilde{x}_n)\|. \] (34)

Hence, by (28), (33), and (34), we also obtain
\[ \|x_{n+1} - Tx_n\| \leq \frac{\alpha_n}{1 - \alpha_n} \|\tilde{x}_n - x_n\| + \lambda_{n+1} \|F(T\tilde{x}_n)\| \rightarrow 0. \] (35)

Using Steps 2 and 3, it is easy to obtain the following corollary.

**Corollary 14.** Consider \( \|x_n - Tx_n\| \rightarrow 0 \).
Applying Steps 2 and 3, one gets
\[ \|x_{n+1} - Tx_n\| \rightarrow 0, \quad \|x_{n+1} - x_n\| \rightarrow 0, \] (36)
so it is easy to see that
\[ \|x_n - Tx_n\| \leq \|x_{n+1} - Tx_n\| + \|x_{n+1} - x_n\| \rightarrow 0. \] (37)

**Step 4.** Consider \( \lim_{n \rightarrow \infty} \sup \langle -F(x^*), T\tilde{x}_n - x^* \rangle \leq 0 \).
For some \( \tilde{x} \in H \), there exits \( \{T\tilde{x}_n\} \rightarrow \tilde{x} \) weakly and such that
\[ \lim_{n \rightarrow \infty} \sup \langle -F(x^*), Tx_n - x^* \rangle = \lim_{n \rightarrow \infty} \sup \langle -F(x^*), Tx_n - x^* \rangle. \] (38)

According to \( \{T\tilde{x}_n\} \rightarrow \tilde{x} \), we have
\[ \tilde{x} \in \text{Fix}(T) = K. \] (39)

By \( x^* \) being the unique solution of VI\((F, K)\), we can obtain
\[ \lim_{n \rightarrow \infty} \sup \langle -F(x^*), Tx_n - x^* \rangle = \lim_{n \rightarrow \infty} \sup \langle -F(x^*), \tilde{x} - x^* \rangle \leq 0. \] (40)

Since \( \|T\tilde{x}_n - Tx_n\| \leq \|\tilde{x}_n - x_n\| \rightarrow 0 \), we immediately conclude that
\[ \lim_{n \rightarrow \infty} \sup \langle -F(x^*), T\tilde{x}_n - x^* \rangle \leq \lim_{n \rightarrow \infty} \sup \langle -F(x^*), T\tilde{x}_n - x_n \rangle + \lim_{n \rightarrow \infty} \sup \langle -F(x^*), Tx_n - x^* \rangle \leq \lim_{n \rightarrow \infty} \sup \langle -F(x^*), Tx_n - x^* \rangle \leq 0. \] (41)

**Step 5.** By Step 1 and Lemma 1, we have
\[ \|x_{n+1} - x^*\|^2 \leq \|\alpha_n (\tilde{x}_n - x^*) + (1 - \alpha_n) (T_{t_n}^{\lambda_n} \tilde{x}_n - x^*)\|^2 \leq \|\alpha_n (\tilde{x}_n - x^*)\|^2 + (1 - \alpha_n) \lambda_{n+1} \|F(\tilde{x}_n)\|^2 \leq \alpha_n \|\tilde{x}_n - x^*\|^2 + (1 - \alpha_n) \|\tilde{x}_n - x^*\|^2 + 2 (T_{t_n}^{\lambda_{n+1}} \tilde{x}_n - T_{t_n}^{\lambda_{n+1}} x^*) + (1 - \alpha_n) \lambda_{n+1} (1 - \gamma) \|F(x^*)\| + (1 - \alpha_n) \lambda_{n+1} (1 - \gamma) \|F(x^*)\|^2 + 2 \lambda_{n+1} \|F(\tilde{x}_n)\|^2 \leq \alpha_n \|\tilde{x}_n - x^*\|^2 + (1 - \alpha_n) \lambda_{n+1} (1 - \gamma) \|F(x^*)\| + (1 - \alpha_n) \lambda_{n+1} (1 - \gamma) \|F(x^*)\|^2 + 2 \lambda_{n+1} \|F(\tilde{x}_n)\|^2. \] (42)
Abstract and Applied Analysis

where

\[
w''_{n+1} = 2t \left\langle -F(x^*), T\bar{x}_n - x^* - t\lambda_{n+1} F(T\bar{x}_n) \right\rangle / \tau (1 - \alpha_n) + \varphi_n / \tau (1 - \alpha_n) + \xi_n / \tau (1 - \alpha_n).
\]

(43)

\[\varphi_n = (1 - \gamma_n) \gamma M,\]
\[\xi_n = (1 - \alpha_n) (1 - \lambda_{n+1}) \beta_n M + (1 - \alpha_n) (1 - \gamma_n) \lambda_{n+1} \gamma M,\]

and \(M_0 \ll M < \infty\).

Denote

\[
s'_{n+1} = \|x_{n+1} - x^*\|, \quad u_n = (1 - \alpha_n) \lambda_{n+1} \tau.
\]

(44)

We can rewrite (42) as

\[
s'_{n+1} \leq (1 - u_n) s'_n + u_n w'_n + 0.
\]

(45)

In fact, \(u_n, w'_n\) satisfies Lemma 5; according to

\[
\lim_{n \to \infty} \beta_n = 1, \quad \lim_{n \to \infty} \gamma_n = 1, \quad \lim_{n \to \infty} \lambda_n = 0,
\]

we obtain

\[
\varphi_n / \tau (1 - \alpha_n) \to 0, \quad \xi_n / \tau (1 - \alpha_n) \to 0.
\]

(47)

Moreover, by Step 4, we also obtain

\[
\lim_{n \to \infty} \frac{2t \left\langle -F(x^*), T\bar{x}_n - x^* - t\lambda_{n+1} F(T\bar{x}_n) \right\rangle}{\tau (1 - \alpha_n)} \leq 2t \lim_{n \to \infty} \sup \left\langle -F(x^*), T\bar{x}_n - x^* \right\rangle + \lambda_{n+1} \left\langle -F(x^*), -tF(T\bar{x}_n) \right\rangle \leq \frac{2t}{\tau} \lim_{n \to \infty} \sup \left\langle -F(x^*), T\bar{x}_n - x^* \right\rangle + \lim_{n \to \infty} \sup \lambda_{n+1} \left\langle -F(x^*), -tF(T\bar{x}_n) \right\rangle \leq 0 + 0 = 0.
\]

(48)

Furthermore, by (43), (47), and (48), it is easy to obtain

\[
\lim_{n \to \infty} \sup w'_{n} \leq 0.
\]

(49)

Consequently apply Lemma 5 to obtain

\[
\|x_n - x^*\| \to 0.
\]

(50)

\]

\[
\|x_n - x^*\| \to 0.
\]

(50)

\]

\[
\|x_n - x^*\| \to 0.
\]

(50)

4. Numerical Experiments

The problem considered in this section is

\[
\min \left\{ \frac{1}{2} \|X - C\|_F^2 \mid X \in K \right\},
\]

(51)

where \(\| \cdot \|_F\) is the matrix Frobenius norm; that is,

\[
\|C\|_F = \left( \sum_{i=1}^{\infty} \sum_{j=1}^{\infty} |C_{ij}|^2 \right)^{1/2}.
\]

(52)

Note that the matrix Frobenius norm is induced by the inner product

\[
\langle A, B \rangle = \text{Trace} (A^T B).
\]

(53)

The problems arise from finance and statistics, and we form the test problems similarly as in [9, 21].

Let \(K = S^n_t \cap \mathcal{B}\), where

\[
S^n_t = \{ H \in \mathbb{R}^{n \times n} \mid H^T = H, H \succeq 0 \},
\]

\[
\mathcal{B} = \{ H \in \mathbb{R}^{n \times n} \mid H^T = H, H_L \leq H \leq H_U \}.
\]

(54)

Let \(H_L, H_U\) be given \(n \times n\) symmetric matrices, and \(C\) asymmetric which differs from previous approaches [9, 21], and it is to be noted that the extended contraction method (EC method) [9] has much difficulty in computing the examples when \(C\) is asymmetric, where \(H_L \leq H_U\) in element-wise:

\[
H_L \leq H_U : (H_L)_{ij} \leq (H_U)_{ij} \quad \forall i, j = 1, \ldots, n.
\]

(55)

Then (51) is equivalent to the following variational inequality:

\[
\left\langle X' - X, \nabla \left( \frac{1}{2} \|X - C\|^2 \right) \right\rangle \geq 0, \quad \forall X' \in K.
\]

(56)

So we get

\[
\left\langle X' - X, X - C \right\rangle \geq 0, \quad \forall X' \in K.
\]

(57)

According to Condition 10, we take the following parameter sequences, and let Condition 10 denote the parameter sequences:

\[
\alpha_n = \frac{1}{10 \ln n}, \quad \lambda_n = \lambda_n' = \lambda_n'' = \frac{1}{10 \ln (n+1)}, \quad \beta_n = \gamma_n = 1 - \frac{1}{10 \ln n}, \quad \rho = t = c_0 > 0.
\]

(58)

According to Condition 12, we take the following parameter sequences, and let Condition 12 denote the parameter sequences:

\[
\alpha_n = 0.8 - \frac{1}{10 \ln n}, \quad n = 2k,
\]

\[
\alpha_n = 0.3 - \frac{1}{10 \ln n}, \quad n = 2k - 1,
\]

\[
\alpha_n = 0.8 - \frac{1}{10 \ln n}, \quad n = 2k,
\]

\[
\alpha_n = 0.3 - \frac{1}{10 \ln n}, \quad n = 2k - 1,
\]
Table 1: Numerical results for the PRH method and the EC method.

| Asymmetric matrix | \( c_0 = 0.1, \theta_n = 0.8, \text{tolerance} = 10^{-4} \) | EC method |
|-------------------|---------------------------------|-----------|
| \( n \) | \( \text{Lt} \) | \( \text{cpu} \) | \( \text{Lt} \) | \( \text{cpu} \) | \( \text{Lt} \) | \( \text{cpu} \) | \( \text{tolerance} \) |

Matlab code:

\[
C = \text{zeros}(n, n); \quad HU = \text{ones}(n, n) \ast 0.1; \quad HL = -HU;
\]

for \( i = 1 : n \)

for \( j = 1 : n \)

\[
t = \text{mod}(t \ast 42108 + 13846, 46273);
C(i, j) = t \ast 2/46273 - 1;
\]

end;

end;

for \( i = 1 : n \)

\[
C(i, i) = \text{abs}(C(i, i)) \ast 2; \quad HU(i, i) = 1; \quad HL(i, i) = 1;
\]

end;

Algorithm 1

\[
\gamma_n = 1 - \frac{1}{\ln n}, \quad n = 2k,
\]

\[
\gamma_n = 1 - \frac{1}{\ln (2n)}, \quad n = 2k - 1,
\]

\[
\gamma = \rho = t = c_0 > 0.
\]

(59)

Obviouly, we have much difficulty in computing the projection of \( P_K[X] \), for all \( x \in S^n \). In order to reduce the difficulty and complexity of computing the projection \( P_K \), we define \( TX \) by

\[
TX = H(G(X)),
\]

where

\[
G(X) = \min \left( H_U, \max \left( X, H_L \right) \right),
\]

\[
H(X) = P_{S^n}(X),
\]

which can be computed without difficulty and the fixed point set of \( \text{Fix}(T') = K \). According to Theorems 11 and 13, the sequences generated by Algorithm 8 under Conditions 10 and 12 are convergent.

The computation begins with ones \((n, n)\) in MATLAB and stops as soon as \( \|x_{k+1} - x_k\| \leq 10^{-3} \) or \( 10^{-2} \). All codes were implemented in MATLAB 7.1 and ran at a Pentium R 1.70G processor, 2G Acer note computer.

We test the problems with \( n = 100, 200, 300, 400, 500, 1000, \) and 2000. The test results with the PRH method under
Table 4: Numerical results for tolerance $10^{-4}$.

| 500               | 392           | 977.79         | 394           | 1012.57        | 378           | 948.44         | 386           | 953.91         | 390           | 971.10         |

Matlab code:

```matlab
C = zeros(n, n); HU = ones(n, n) * 0.1; HL = -HU;
for i = 1: n
    for j = 1: n
        C = -1 + 2 * rand(n);
    end;
end;
for i = 1: n
    C(i, i) = abs(C(i, i)) * 2; HU(i, i) = 1; HL(i, i) = 1;
end;
```

Algorithm 2

5. Conclusions

We have proved the strong convergence of PRH method under Condition 12, which differs from Condition 10. The result can be considered as an improvement and refinement of the previous results [14]. And more importantly, numerical experiments demonstrated that the PRH method under Condition 12 is more efficient than that under Condition 10, and the PRH method under some descent directions is more slightly efficient than that of the MRHSD method [14, 16], and it is easy to obtain these descent directions. Furthermore, it is important to find $\gamma$, $\rho$, and $t$ by Tables 2 and 4.

This research was supported by National Science and Technology Support Program (Grant no. 2011BAH24B06), Joint Fund of National Natural Science Foundation of China and Civil Aviation Administration of China (Grant no. U1233105), and Science Foundation of the Civil Aviation Flight University of China (Grant no. J2010-45).

different conditions are reported in Tables 1, 2, 3, and 4. And the CPU time is in seconds. It is to be noted that the results of extended contraction method are only given out when the iteration step (lt) is less than or equal to 100.

Test Examples 1. In this example we generate the data in a similar manner as in [9]. The entries of diagonal elements of $C$ are randomly generated in the interval $(0, 2)$; the entries of off-diagonal elements of $C$ are randomly generated in the interval $(-1, 1)$ (Algorithm 1):

$$(H_U)_{jj} = (H_L)_{jj} = 1,$$

$$(H_U)_{ij} = -(H_L)_{ij} = 0.1, \quad \forall i \neq j, i, j = 1, 2, \ldots, n.$$  \hspace{1cm} (62)

When $n \geq 1000$ and tolerance $10^{-4}$, the computation time of the proposed method is too long, so the results of the PRH method give out approximate solution with $n \geq 1000$ and tolerance $10^{-3}$ in the following. And the extended contraction method (EC method) has much difficulty in computing the examples when $C$ is asymmetric. Furthermore, by introducing auxiliary variable, the certain projection method or relaxed-PPA method [10] can be implemented by these tests.

Test Examples 2. We form the data of the second problems similarly as in the first test examples. The entries of diagonal elements of $C$ are randomly generated in the interval $(0, 2)$; the entries of off-diagonal elements of $C$ are generated from a uniform distribution in the same interval (Algorithm 2):

$$(H_U)_{jj} = (H_L)_{jj} = 1,$$

$$(H_U)_{ij} = -(H_L)_{ij} = 0.1, \quad \forall i \neq j, i, j = 1, 2, \ldots, n.$$  \hspace{1cm} (63)

From Tables 1 to 3, we found that the iteration numbers and CPU time of PRH under Condition 12 are more efficient than that under Condition 10. In Table 4 of our method, the tests’ results give out that the PRH method under some descent directions is more slightly efficient than those of the MRHSD method [14, 16], and it is easy to obtain these descent directions. Furthermore, it is important to find $\gamma$, $\rho$, and $t$ by Tables 2 and 4.

5. Conclusions

We have proved the strong convergence of PRH method under Condition 12, which differs from Condition 10. The result can be considered as an improvement and refinement of the previous results [14]. And more importantly, numerical experiments demonstrated that the PRH method under Condition 12 is more efficient than that under Condition 10, and the PRH method under some descent directions is more slightly efficient than that of the MRHSD method.

How to select parameters of the PRH method for solving variational inequalities is worthy of further investigations in the future.

A New Implementable Prediction-Correction Method for Monotone Variational Inequalities with Separable Structure

Feng Ma, Mingfang Ni, and Zhanke Yu

Institute of Communications Engineering, PLA University of Science and Technology, Nanjing 210007, China

Received 30 June 2013; Accepted 27 August 2013

1. Introduction

The variational inequality (VI(Ω, F)) in the finite-dimensional space is to determine a vector \( u \in \Omega \) such that
\[
\langle u' - u, F(u) \rangle \geq 0, \quad \forall u' \in \Omega,
\]
where \( \Omega \subseteq \mathbb{R}^n \) is a nonempty closed convex subset and \( F \) is a continuous mapping from \( \mathbb{R}^n \) into itself. The VI(Ω, F) has found many efficient applications in a broad spectrum of areas such as traffic equilibrium [1] and network economic problems [2].

In this paper, we consider the following variational inequalities: find a vector \( w \in D \) such that
\[
\langle w' - w, F(w) \rangle \geq 0, \quad \forall w' \in D,
\]
with
\[
D = \{(x, y) \mid x \in X, y \in Y, Ax + By = b\},
\]
where \( D \subseteq \mathbb{R}^{n+p} \) is a nonempty closed convex subset and \( f : X \to \mathbb{R}^n \) and \( g : Y \to \mathbb{R}^p \) are monotone operators. Problem (5) is referred to as a structured variational inequality (SVI) [6].
By attaching a Lagrange multiplier vector $\lambda \in \mathbb{R}^m$ to the linear constraints $Ax + By = b$, the VI problem (5) is converted into the following form:

\[
\begin{align*}
\langle x' - x, f(x) - A^T\lambda \rangle + \langle y' - y, g(y) - B^T\lambda \rangle + \langle \lambda' - \lambda, Ax + By - b \rangle & \geq 0, \quad \forall u' \in \Omega, \\
\end{align*}
\]

where

\[
\Omega = \mathcal{X} \times \mathcal{Y} \times \mathbb{R}^m.
\]

The compact form is

\[
\langle u' - u, F(u) \rangle \geq 0, \quad \forall u' \in \Omega,
\]

with

\[
F(u) := \begin{pmatrix}
\langle x, A^T\lambda \rangle \\
\langle y, B^T\lambda \rangle \\
\langle \lambda, Ax + By - b \rangle
\end{pmatrix}.
\]

For the purpose of parallel computing, the proximal alternating directions method (PADM) generates $u^{k+1} = u^k - \alpha_k (u^k - u)$, and $\bar{\lambda}^{k+1} = \lambda^k - \beta (A\bar{x}^k + B\bar{y}^k - b)$. Note that when $r = s = 0$ in (11)-(12), the classical alternating directions method (ADM) is recovered.

The rest of this paper is organized as follows. In Section 2, we review some preliminaries which are useful for further analysis. In Section 3, we present the new implementable prediction-correction method for SVI, and the global convergence result is established.

### 2. Preliminaries

In this section, we make some standard assumptions and summarize some basic properties of VI which will be used in the subsequent discussions.

**Assumption**

(A1) $\mathcal{X}$, $\mathcal{Y}$ are simple closed convex sets.

A set which is said to be simple means that the projection onto the set is easy to compute, where the projection of a point $v$ onto the closed convex set $\Omega$, denoted by $P_\Omega(v)$, is defined as the nearest point $u \in \Omega$ to $v$; that is,

\[
P_\Omega(v) = \arg \min \{ \| u - v \| \ | u \in \Omega \}.
\]

(A2) The mapping $F : \mathbb{R}^n \to \mathbb{R}^n$ is said to be monotone on $\Omega$ if

\[
\langle u - v, F(u) - F(v) \rangle \geq 0, \quad \forall u, v \in \Omega.
\]
Abstract and Applied Analysis

(A3) The solution set of SVI(Ω,F), denoted by Ω∗, is nonempty.

Properties. Let G be a symmetric positive definite matrix; the G-norm of the vector u is denoted by \( \|u\|_G := \sqrt{\langle u, Gu \rangle} \). In particular, when \( G = I \), \( \|u\| := \sqrt{\langle u, u \rangle} \) is the Euclidean norm of u. For a matrix \( A \), \( \|A\| \) denotes its norm \( \|A\| := \max \{\|Ax\| : \|x\| \leq 1\} \).

The following well-known properties of the projection operator will be used in the coming analysis.

Lemma 1. Let \( \Omega \in \mathbb{R}^n \) be a nonempty closed convex set; let \( P_\Omega(\cdot) \) be the projection operator onto \( \Omega \) under the \( G \)-norm. Then

\[
\langle u' - P_\Omega(u'), G (u - P_\Omega(u')) \rangle \leq 0, \quad \forall u' \in \mathbb{R}^n, \quad \forall u \in \Omega,
\]

\[
\|P_\Omega(u) - P_\Omega(u')\|_G \leq \|u - u'\|_G, \quad \forall u, u' \in \mathbb{R}^n,
\]

\[
\|u - P_\Omega(u')\|^2_2 \leq \|u - u'\|^2_G - \|u' - P_\Omega(u')\|^2_G,
\]

\[
\quad \forall u' \in \mathbb{R}^n, \quad \forall u \in \Omega.
\]

For any arbitrary positive scalar \( \beta \) and \( u \in \Omega \), let \( e(u, \beta) \) denote the residual function associated with the mapping \( F \); that is,

\[
e(u, \beta) = u - P_\Omega[u - \beta F(u)].
\]

Lemma 2. \( u^* \) is a solution of the SVI(Ω,F) if and only if \( e(u^*, \beta) = 0 \) for any given positive constant \( \beta \) (see [2, page 267]).

Lemma 3. Solving SVI(Ω,F) (7) is equivalent to find a zero point of the mapping

\[
e(u, \beta) := \begin{pmatrix} e_1(u, \beta) \\ e_2(u, \beta) \\ e_3(u, \beta) \end{pmatrix} = \begin{pmatrix} x - P_X \left\{ x - \beta \left[ f(x) - A^T \lambda \right] \right\} \\ y - P_Y \left\{ y - \beta \left[ g(y) - B^T \lambda \right] \right\} \\ \beta (Ax + By - b) \end{pmatrix}.
\]

3. The New Algorithm

In this section, we present a new prediction-correction method for SVI(Ω,F) and show its global convergence. But, at the beginning, to make the algorithm more succinct, we first define some matrices:

\[
H = \begin{pmatrix} rI & 0 & 0 \\ 0 & sI & 0 \\ 0 & 0 & \frac{1}{\beta}I \end{pmatrix}, \quad M = \begin{pmatrix} I & 0 & \frac{1}{r}A^T \\ 0 & I & \frac{1}{s}B^T \\ 0 & 0 & I \end{pmatrix},
\]

\[
Q = \begin{pmatrix} rI & 0 & A^T \\ 0 & sI & B^T \\ 0 & 0 & \frac{1}{\beta}I \end{pmatrix}.
\]

Obviously, \( H \) is a symmetric positive definite matrix whenever \( r > 0, s > 0, \) and \( \beta > 0 \), and we also have \( Q = HM \).

3.1. Description of the Algorithm

Algorithm 4. It is a prediction-correction-based algorithm for the SVI(Ω,F).

Phase 1 (initialization step). Given a small number \( \epsilon > 0 \), let \( \gamma \in (0, 2) \); matrices \( Q, M \) are defined in (20). Take \( u^0 \in \mathbb{R}^{n+p+m} \); set \( k = 0 \). Choose the parameters \( r > 0, s > 0, \) and \( \beta > 0 \) such that

\[
r > 2\beta \|A^T A\|, \quad s > 2\beta \|B^T B\|.
\]

Phase 2 (prediction step). Generate the predictor \( \tilde{x}^k \) via solving the following projection equation:

\[
\tilde{x}^k = P_X \left\{ x^k - \frac{1}{r} \left[ f \left( \tilde{x}^k \right) - A^T \lambda^k \right] \right\}.
\]

Then find an \( \tilde{y}^k \in \mathbb{Y} \) such that

\[
\tilde{y}^k = P_Y \left\{ y^k - \frac{1}{s} \left[ g \left( \tilde{y}^k \right) - B^T \lambda^k \right] \right\}.
\]

Finally, update \( \tilde{\lambda}^k \) via

\[
\tilde{\lambda}^k = \lambda^k - \beta \left( A \tilde{x}^k + B \tilde{y}^k - b \right).
\]

Phase 3 (correction step). Correct the predictor, and generate the new iterate \( u^{k+1} \) via

\[
u^{k+1} = u^k - \alpha^k M \left( u^k - \tilde{u}^k \right),
\]

where

\[
\alpha^k = \gamma \alpha^*_k, \quad \alpha^*_k = \frac{\langle u^k - \tilde{u}^k, Q (u^k - \tilde{u}^k) \rangle}{\|M (u^k - \tilde{u}^k)\|_H^2}.
\]

Phase 4 (convergence verification). If \( \|u^k - u^{k+1}\| \leq \epsilon \), stop; otherwise set \( k := k + 1 \); go to Phase 2.
Remark 5. Note that (22) does not involve \( \tilde{x}^k \) and that (23) is independent on the \( \tilde{x}^k \) generated by (22). Hence the two projections (22) and (23) are eligible for parallel computation.

Remark 6. It is easy to check that \( \tilde{u}^k = (\tilde{x}^k, \tilde{y}^k, \tilde{\lambda}^k) \) is a solution of SVI \( (\Omega, F) \) if and only if \( Ax^k = A\tilde{x}^k, \ By^k = B\tilde{y}^k, \) and \( \lambda^k = \tilde{\lambda}^k \). Thus, it is reasonable to take the magnitude of \( \|u^k - \tilde{u}^k\| \leq \varepsilon \) as the stopping criterion.

Remark 7. The strategy of choosing the step size \( \alpha_k \) in the correction step which coincides with the strategy in He’s papers, see, for example, [19], will be explained in detail in the following section.

Remark 8. Our method and the methods proposed in [6, 15, 20] are all in the prediction-correction algorithm framework, where at each iteration they make a prediction step to produce a predictor and a correction step to generate the new iterate via correcting this predictor.

3.2. Contractive Properties. Now, we start to prove some properties of the sequence \( \{\tilde{u}^k\} \). The first lemma quantifies the discrepancy between the point \( \tilde{u}^k \) and a solution point of SVI \( (\Omega, F) \).

Lemma 9. Let \( \{\tilde{u}^n\} \) be generated by (22)–(24), and let the matrix \( M \) be given in (20). Then one has

\[
\langle u' - \tilde{u}^k, F(\tilde{u}) - Q(\tilde{u}^k - \tilde{u}^k) \rangle \geq 0, \quad \forall u' \in \Omega. \tag{27}
\]

Proof. Note that \( \tilde{u}^k \) generated by (22)–(24) are actually solutions of the following VIs:

\[
\begin{align*}
\langle x' - \tilde{x}^k, f(\tilde{x}^k) - A^T\lambda^k - r(x^k - \tilde{x}^k) \rangle & \geq 0, \quad \forall x \in \mathcal{X}, \tag{28} \\
\langle y' - \tilde{y}^k, g(\tilde{y}^k) - B^T\lambda^k - s(y^k - \tilde{y}^k) \rangle & \geq 0, \quad \forall y \in \mathcal{Y}, \tag{29} \\
\langle \lambda' - \tilde{\lambda}^k, A\tilde{x}^k + B\tilde{y}^k - \beta - \frac{1}{\beta}(\lambda^k - \tilde{\lambda}^k) \rangle & \geq 0, \quad \forall \lambda \in \mathcal{R}^m. \tag{30}
\end{align*}
\]

Combining (28)–(30) together, we have

\[
\begin{align*}
\begin{pmatrix}
x' - \tilde{x}^k, f(\tilde{x}^k) - A^T\tilde{\lambda}^k - A^T(\lambda^k - \tilde{\lambda}^k) - r(x^k - \tilde{x}^k) \\
y' - \tilde{y}^k, g(\tilde{y}^k) - B^T\tilde{\lambda}^k - B^T(\lambda^k - \tilde{\lambda}^k) - s(y^k - \tilde{y}^k) \\
\lambda' - \tilde{\lambda}^k, A\tilde{x}^k + B\tilde{y}^k - \beta - \frac{1}{\beta}(\lambda^k - \tilde{\lambda}^k)
\end{pmatrix} \\
\geq 0, \quad \forall u' \in \Omega.
\end{align*}
\]

(31)

Using the notations of \( F \) (see (10)) and \( Q \) (see (20)), the earlier inequality can be rewritten into

\[
\langle u' - \tilde{u}^k, F(\tilde{u}) - Q(\tilde{u}^k - \tilde{u}^k) \rangle \geq 0, \quad \forall u' \in \Omega. \tag{32}
\]

The assertion (27) is thus proved.

The following lemma plays a key role in proving the convergence of the algorithm.

Lemma 10. Let matrices \( Q, H \) be defined in (20), if the parameters \( r > 0, s > 0, \) and \( \beta > 0 \) in (22)–(24) satisfy

\[
r > 2\beta\|A^TA\|, \quad s > 2\beta\|B^TB\|. \tag{33}
\]

Then for the matrix \( Q \) in (27), one has

\[
\langle u - \tilde{u}, Q(u - \tilde{u}) \rangle \geq \left( 1 - \frac{1}{2} \right)\|u - \tilde{u}\|_H^2 \tag{34}
\]

\[
\forall u \neq \tilde{u} \in \mathcal{R}^{n+p+m},
\]

with

\[
\mu = \sqrt{\max \left\{ \frac{2\beta}{r}, \frac{2\beta}{s} \right\}} \in (0, 1). \tag{35}
\]

Proof. For any \( u \neq \tilde{u} \), we have

\[
\langle u - \tilde{u}, Q(u - \tilde{u}) \rangle = \|u - \tilde{u}\|_H^2 \geq \langle \lambda - \tilde{\lambda}, A(x - \tilde{x}) \rangle + \langle \lambda - \tilde{\lambda}, y - \tilde{y} \rangle. \tag{36}
\]

According to the Cauchy-Schwarz inequality, we get

\[
\begin{align*}
\langle \lambda - \tilde{\lambda}, A(x - \tilde{x}) \rangle + \langle \lambda - \tilde{\lambda}, y - \tilde{y} \rangle \\
&= \frac{1}{2} \left( 2 \langle \lambda - \tilde{\lambda}, A(x - \tilde{x}) \rangle + 2 \langle \lambda - \tilde{\lambda}, B(y - \tilde{y}) \rangle \right) \\
&\geq -\frac{1}{2} \left( \frac{2\beta}{\mu} \|A(x - \tilde{x})\|^2 + \frac{\mu}{2\beta} \|\lambda - \tilde{\lambda}\|^2 \right) \\
&\quad - \frac{1}{2} \left( \frac{2\beta}{\mu} \|B(y - \tilde{y})\|^2 + \frac{\mu}{2\beta} \|\lambda - \tilde{\lambda}\|^2 \right) \\
&= -\frac{1}{2} \left( \frac{2\beta}{\mu} \|A(x - \tilde{x})\|^2 + \frac{2\beta}{\mu} \|B(y - \tilde{y})\|^2 \right) \\
&\quad \times \|B(y - \tilde{y})\|^2 + \frac{\mu}{2\beta} \|\lambda - \tilde{\lambda}\|^2 \right) \tag{37}
\end{align*}
\]

With the \( \mu \) defined in (35), we have

\[
\begin{align*}
\frac{2\beta}{\mu} \|A(x - \tilde{x})\|^2 & \leq \mu r \|x - \tilde{x}\|^2, \tag{38} \\
\frac{2\beta}{\mu} \|B(y - \tilde{y})\|^2 & \leq \mu s \|y - \tilde{y}\|^2.
\end{align*}
\]

Substituting (38) into (37), combining (36), the assertion (34) is proved.

Lemma 11. Suppose that \( u^* = (x^*, y^*, \lambda^*) \in \Omega \) is a solution point of (9) and the sequences \( \{u^{k+1}\} \) are corrected by an undeterminate step size denoted by \( \alpha \) instead of (26); that is,

\[
u^{k+1} = u^k - \alpha M(u^k - \tilde{u}^k). \tag{39}
\]
Thus, on the other hand, since combining (42)–(43) together, we have
\[ \varphi^k(\alpha) = 2\alpha \left\langle u^k - \tilde{u}^k, Q(u^k - \tilde{u}^k) \right\rangle - \alpha^2 \| M(u^k - \tilde{u}^k) \|^2_H. \]

Proof. One can see that
\[
\vartheta^k(\alpha) = \| u^k - u^* \|^2_H - \| u^{k+1} - u^* \|^2_H
= \| u^k - u^* \|^2_H - \| u^k - \alpha M(u^k - \tilde{u}^k) - u^* \|^2_H
= 2\alpha \left\langle u^k - u^*, HM(u^k - \tilde{u}^k) \right\rangle
- \alpha^2 \| M(u^k - \tilde{u}^k) \|^2_H.
\] (41)

On the other hand, since \( Q = HM \), using the monotonicity of \( F \) and Lemma 9, we have
\[
\left\langle u^k - u^*, HM(u^k - \tilde{u}^k) \right\rangle = \left\langle u^k - u^*, Q(u^k - \tilde{u}^k) \right\rangle
= \left\langle u^k - \tilde{u}^k, Q(u^k - \tilde{u}^k) \right\rangle
+ \left\langle u^k - \tilde{u}^k, Q(u^k - \tilde{u}^k) \right\rangle
\geq \left\langle u^k - \tilde{u}^k, Q(u^k - \tilde{u}^k) \right\rangle
+ \left\langle u^k - \tilde{u}^k, F(\tilde{u}^k) \right\rangle
\geq \left\langle u^k - \tilde{u}^k, Q(u^k - \tilde{u}^k) \right\rangle
+ \left\langle \tilde{u}^k - u^*, F(u^*) \right\rangle
\geq \left\langle u^k - \tilde{u}^k, Q(u^k - \tilde{u}^k) \right\rangle.
\] (43)

Combining (42)–(43) together, we have
\[
\vartheta^k(\alpha) = 2\alpha \left\langle u^k - u^*, Q(u^k - \tilde{u}^k) \right\rangle
- \alpha^2 \| M(u^k - \tilde{u}^k) \|^2_H
\geq 2\alpha \left\langle u^k - \tilde{u}^k, Q(u^k - \tilde{u}^k) \right\rangle
- \alpha^2 \| M(u^k - \tilde{u}^k) \|^2_H
= \varphi^k(\alpha).
\] (44)

Thus, \( \varphi^k(\alpha) \) is a lower bound of \( \vartheta^k(\alpha) \) for any \( \alpha > 0 \). \( \square \)

Remark 12. Note that \( \varphi^k(\alpha) \) is a quadratic function of \( \alpha \) and it reaches its maximum at
\[
\alpha_k^* = -\frac{\left\langle u^k - \tilde{u}^k, Q(u^k - \tilde{u}^k) \right\rangle}{\| M(u^k - \tilde{u}^k) \|^2_H}.
\] (45)

Hence, it is reasonable to use the step size strategy (26). The parameter \( \gamma \) in (26) plays the role of a relaxation or scaling parameter. We can easily see that \( \gamma \in (0, 2) \) can ensure convergence.

Now, we prove the Fejér monotonicity of the iterative sequence \( \{u^k\} \) generated by the algorithm.

**Theorem 13.** Suppose that \( u^* = (x^*, y^*, \lambda^*) \in \Omega \) is a solution point of (9) and the sequences \( \{u^k\} \) are generated by the algorithm. Then
\[
\|u^{k+1} - u^*\|^2_H \leq \|u^k - u^*\|^2_H - \frac{1}{2} \gamma (2 - \gamma) \alpha_k
- \frac{1}{2} \gamma (2 - \gamma) \alpha_k^* (1 - \mu) \|u - \tilde{u}\|^2_H.
\] (46)

Proof. According to Lemma 11,
\[
\|u^{k+1} - u^*\|^2_H \leq \|u^k - u^*\|^2_H - \varphi^k(\alpha_k)
= \|u^k - u^*\|^2_H - (2\alpha_k \left\langle u^k - \tilde{u}^k, Q(u^k - \tilde{u}^k) \right\rangle
- \alpha_k^2 \| M(u^k - \tilde{u}^k) \|^2_H)
\geq \|u^k - u^*\|^2_H - \gamma (2 - \gamma) \alpha_k^* (1 - \mu) \|u - \tilde{u}\|^2_H.
\] (47)

Moreover, it follows from (26) that the step size
\[
\alpha_k^* = \frac{\|u^k - \tilde{u}^k\|^2_{Q+Q^T}}{2\| M(u^k - \tilde{u}^k) \|^2_H - 2\|u^k - \tilde{u}^k\|^2_{M^THM}}
= \frac{1}{2} \left( \left( \|u^k - \tilde{u}^k\|^2_{M^THM} + r \|x^k - \tilde{x}^k\|^2 + s \|y^k - \tilde{y}^k\|^2 \right)
+ \left( \frac{1}{\beta} \|x^k - \tilde{x}^k\|^2 - \frac{1}{r} \|A^T(\lambda^k - \tilde{\lambda}^k)\|^2
- \frac{1}{s} \|A^T(\lambda^k - \tilde{\lambda}^k)\|^2 \right) \right)
\times \left( \left( \|u^k - \tilde{u}^k\|^2_{M^THM} \right)^{-1} \right)
\geq \frac{1}{2} \left( \left( \|u^k - \tilde{u}^k\|^2_{M^THM} + r \|x^k - \tilde{x}^k\|^2 + s \|y^k - \tilde{y}^k\|^2 \right)
+ \left( \frac{1}{\beta} - \frac{1}{r} \|A^T A - \frac{1}{s} \|A^T B\| \|\lambda^k - \tilde{\lambda}^k\|^2 \right) \times \left( \|u^k - \tilde{u}^k\|^2_{M^THM} \right)^{-1} \right).
\] (48)
Based on the conditions (33), we have
\[
\begin{align*}
    r\|x^k - x^h\|^2 + s\|y^k - y^h\|^2
    &+ \left(1 - \frac{1}{\beta} - \frac{1}{r} A^T A - \frac{1}{s} B^T B\right)\|\lambda^k - \lambda^h\|^2 \\
    &\geq 0.
\end{align*}
\]
Hence,
\[
\alpha_k^* \geq \frac{1}{2}\|\mu^k - \mu^h\|^2_{M_{TH}} = \frac{1}{2}.
\]
Substituting (50) into (47), we have
\[
\begin{align*}
    \|u^{k+1} - u^*\|_x &\leq \|u^k - u^*\|_x^2 \\
    &- \frac{1}{2} (2 - r) \left(1 - \frac{\mu}{2}\right)\|u^k - u^h\|^2.
\end{align*}
\]
Thus, we obtain the assertion of this theorem.

Based on the earlier results, we are now ready to prove the global convergence of the algorithm.

**Theorem 14.** The sequence \(\{u^k\}\) generated by the proposed algorithm converges to a solution of SVI (\(\Omega, F\)).

**Proof.** We prove the convergence of the proposed algorithm by following the standard analytic framework of contraction-type methods. It follows from (46) that \(\{u^k\}\) is bounded, and we have that
\[
\lim_{k \to \infty} \|u^k - u^k\|_H = 0.
\]
Consequently,
\[
\begin{align*}
    \lim_{k \to \infty} \|x^k - x^k\|_x &= 0, \quad \lim_{k \to \infty} \|y^k - y^k\|_y = 0, \\
    \lim_{k \to \infty} \|Ax^k + By^k - b\| &= \lim_{k \to \infty} \frac{1}{\beta} \|\lambda^k - \lambda^k\| = 0,
\end{align*}
\]
since (see (22) and (23))
\[
\begin{align*}
    x^k &= P_x \left[ x^k - \frac{1}{r} \left( f(x^k) - A^T (A \lambda^k) \right) \\
    &+ \left( x^k - x^k \right) + \frac{1}{r} A^T (A \lambda^k - \lambda^k) \right], \\
    y^k &= P_y \left[ y^k - \frac{1}{s} \left( g(y^k) - B^T (A \lambda^k) \right) \\
    &+ \left( y^k - y^k \right) + \frac{1}{s} B^T (A \lambda^k - \lambda^k) \right], \\
    \lambda^k &= \lambda^k - \beta \left( Ax^k + By^k - b \right).
\end{align*}
\]
It follows from (53) that
\[
\begin{align*}
    \lim_{k \to \infty} x^k - P_x \left[ x^k - \frac{1}{r} \left( f(x^k) - A^T (A \lambda^k) \right) \right] &= 0, \\
    \lim_{k \to \infty} y^k - P_y \left[ y^k - \frac{1}{s} \left( g(y^k) - B^T (A \lambda^k) \right) \right] &= 0, \\
    \lim_{k \to \infty} Ax^k + By^k - b &= 0.
\end{align*}
\]
Because \(\tilde{u}^k\) is also bounded, it has at least one cluster point. Let \(u^\infty\) be a cluster point of \(\tilde{u}^k\), and let \(\tilde{u}^{k_j}\) be the subsequence converging to \(u^\infty\). It follows from (55) that
\[
\begin{align*}
    \lim_{j \to \infty} x^{k_j} - P_x \left[ x^{k_j} - \frac{1}{r} \left( f(x^{k_j}) - A^T \lambda^{k_j} \right) \right] &= 0, \\
    \lim_{j \to \infty} y^{k_j} - P_y \left[ y^{k_j} - \frac{1}{s} \left( g(y^{k_j}) - B^T \lambda^{k_j} \right) \right] &= 0, \\
    \lim_{j \to \infty} Ax^{k_j} + By^{k_j} - b &= 0.
\end{align*}
\]
Consequently,
\[
\begin{align*}
    x^\infty - P_x \left[ x^\infty - \frac{1}{r} \left( f(x^\infty) - A^T \lambda^\infty \right) \right] &= 0, \\
    y^\infty - P_y \left[ y^\infty - \frac{1}{s} \left( g(y^\infty) - B^T \lambda^\infty \right) \right] &= 0, \\
    Ax^\infty + By^\infty - b &= 0.
\end{align*}
\]
Using the continuity of \(F\) and the projection operator \(P_\Omega(\cdot)\), we have that \(u^\infty\) is a solution of SVI (\(\Omega, F\)).

On the other hand, by taking limits over the subsequences in (52) and using \(\lim_{j \to \infty} \tilde{u}^{k_j} = u^\infty\), we have that, for any \(k > k_j\), it follows from (46) that
\[
\lim_{k \to \infty} \|u^k - u^\infty\|_H = 0.
\]
Thus, the sequence \(\{u^k\}\) converges to \(u^\infty\), which is a solution of SVI (\(\Omega, F\)).

### 4. Numerical Experiments

In this section, we present some numerical experiments results to show the effectiveness of the proposed algorithm. The codes are run on a notebook computer with Inter(R) Core(TM) 2 CPU 2.0 GHZ and RAM 2.00 GM under MAT-LAB Version 2009b.

We consider the following optimization problem:
\[
\begin{align*}
    \min_{x \in \mathbb{R}^p, y \in \mathbb{R}^r} & \quad \frac{1}{2} x^T Px + \frac{1}{2} y^T Qy \\
    \text{s.t.} & \quad Ax + By = b,
\end{align*}
\]
where \(P \in \mathbb{S}^{r \times r}\), \(Q \in \mathbb{S}^{p \times p}\) are symmetric positive semidefinite matrices, \(A \in \mathbb{R}^{m \times p}\), \(B \in \mathbb{R}^{m \times p}\), and \(b \in \mathbb{R}^m\).

Using the KKT condition, the problem (59) can be converted into the following variational inequality: find \(w^* = (x^*, y^*, \lambda^*) \in \mathbb{R}^{r+p+m}\) such that
\[
\begin{align*}
    x' - x^*, \quad P x^* - A^T \lambda^* \\
    y' - y^*, \quad Q y^* - B^T \lambda^* \\
    \lambda' - \lambda^*, \quad A x^* + B y^* - b
\end{align*}
\]
\[\geq 0, \quad \forall w' \in \mathbb{R}^{r+p+m}.\]

In this example, we randomly created the input data of the tested collection in the following manner.
According to the data generation, we have

\[ \|\mathbf{A}\| = 9 \quad \text{and} \quad \|B\| = 9. \]

To apply (22)–(25) to solve (59), instead of choosing the step length \( \alpha_k \) judiciously as (24), we can simply choose \( \alpha_k \equiv 1 \) by taking \( r = 1/\alpha_k \) (since \( \alpha_k > 1/2 \) when \( u \neq \bar{u} \), we have \( r \in (0, 2) \) which satisfies the requirement). Then, we obtain the following subproblems which are all easy enough to have closed-form solutions:

\[ \tilde{x}^k = (rI + P)^{-1} \left( r\tilde{x}^k + A^T \lambda^k \right), \]
\[ \tilde{y}^k = (sI + Q)^{-1} \left( s\tilde{y}^k + B^T \lambda^k \right), \]
\[ \tilde{\lambda}^k = \lambda^k - \beta (Ax^k + By^k - b), \]
\[ x^{k+1} = \tilde{x}^k - \frac{1}{r} A^T (\lambda^k - \tilde{\lambda}^k), \]
\[ y^{k+1} = \tilde{y}^k - \frac{1}{s} B^T (\lambda^k - \tilde{\lambda}^k), \]
\[ \lambda^{k+1} = \tilde{\lambda}^k. \]  

(i) \( P \) and \( Q \) were generated randomly with eigenvalues in \([5, 10]\) according to the following MATLAB scripts:

\[ P = \text{rand}(n); \quad [Q1, R1] = \text{qr}(P), \]
\[ S = 5 + 5 \cdot \text{rand}(n, 1); \quad P = Q1 \cdot \text{diag}(S) \cdot Q1', \]
\[ Q = \text{rand}(p); \quad [Q2, R2] = \text{qr}(Q), \]
\[ S = 5 + 5 \cdot \text{rand}(n, 1); \quad P = Q2 \cdot \text{diag}(S) \cdot Q2'. \]

(ii) \( A \) and \( B \) were generated randomly with singular values in \([0, 3]\), and the maximum singular value is 3 according to the following MATLAB scripts:

\[ A = \text{rand}(m, n); [U, S, V] = \text{svd}(A), \]
\[ S = S(1, 1) \cdot 3; \quad A = U \cdot S \cdot V', \]
\[ B = \text{rand}(m, p); [U, S, V] = \text{svd}(B), \]
\[ S = S(S(1, 1) \cdot 3; \quad B = U \cdot S \cdot V'. \]

(iii) \( b \) is generated randomly with \( b = \text{rand}(m, 1) \cdot 10. \)

According to the data generation, we have \( \|A^T A\| = 9 \) and \( \|B^T B\| = 9. \)

For comparison, we also solve it by the parallel decomposition method (denoted by PDM) that has been studied extensively in the literature (e.g., [21, 22]). For PDM, the restrictions on the proximal parameters are the same as our algorithm. By applying PDM to (59), we obtain the following subproblems which are also easy enough to have closed-form solutions:

\[ x^{k+1} = (rI + P)^{-1} \left( r\tilde{x}^k + A^T \lambda^k \right), \]
\[ y^{k+1} = (sI + Q)^{-1} \left( s\tilde{y}^k + B^T \lambda^k \right), \]
\[ \lambda^{k+1} = \lambda^k - \beta (Ax^k + By^k - b). \]

We report the numerical experiments by building their performance profiles in terms of the number of iterations and the total of computational time. Here, we take \( \beta = 3 + (n/10), \quad r = s = 20\beta \) for the two algorithms. We set the initial vector \( (x^0, y^0, \lambda^0) = (0, 0, 0) \), and the stopping criterion is

\[ \text{Tol} = \max \left\{ \|x^{k+1} - x^k\|_\infty, \|y^{k+1} - y^k\|_\infty, \|\lambda^{k+1} - \lambda^k\|_\infty \right\} \leq 10^{-4}. \]

The computational results are given in Table 1 for different choices of \( m, n, \) and \( p \). We reported the number of iterations (Iter.) and the computing time in seconds (CPU(s)) when the mentioned stopping criterion is achieved.

The data in Table 1 indicates clearly that the proposed method is efficient compared with the classical PDM in [21, 22]. We can observe that the iteration numbers and the CPU time of the two algorithms are almost the same.

5. Conclusions

In this paper, we proposed a new implementable algorithm for solving the monotone variational inequalities with separable structure. At each iteration, the algorithm performs
two easily implementable projections parallelly to produce a predictor and then makes a simple correction to generate the new iterate. Under some mild conditions, we proved the global convergence of the new method. We also give some numerical experiments to show that the proposed method is applicable and valid.

The purpose of this paper is to extend the convergence analysis of Han and Yuan (2012) for the alternating direction method of multipliers (ADMM) from the strongly convex to a more general case. Under the assumption that the individual functions are composites of strongly convex functions and linear functions, we prove that the classical ADMM for separable convex programming with two blocks can be extended to the case with more than three blocks. The problems, although still very special, arise naturally from some important applications, for example, route-based traffic assignment problems.

1. Introduction

In this paper, we consider the convex programming with separable functions:

\[ \begin{align*}
\min \left\{ \sum_{i=1}^{m} f_i(x_i) \mid \sum_{i=1}^{m} A_i x_i = b, x_i \in X_i, i = 1, 2, \ldots, m \right\}, \\
\end{align*} \tag{1} \]

where \( f_i : \mathbb{R}^{n_i} \to \mathbb{R} \cup \{+\infty\} \) (\( i = 1, 2, \ldots, m \)) are closed proper convex functions (not necessarily smooth); \( A_i \in \mathbb{R}^{l \times n_i} \) (\( i = 1, 2, \ldots, m \)); \( X_i \subseteq \mathbb{R}^{n_i} \) (\( i = 1, 2, \ldots, m \)) are closed convex sets; \( b \in \mathbb{R}^l \) and \( \sum_{i=1}^{m} n_i = n \). Throughout the paper, we assume that the solution set of (1) is nonempty.

For the special case of (1) with \( m = 2 \),

\[ \begin{align*}
\min \left\{ f_1(x_1) + f_2(x_2) \mid A_1 x_1 + A_2 x_2 = b, x_i \in X_i, i = 1, 2 \right\}, \\
\end{align*} \tag{2} \]

the problem has been studied extensively. Among lots of numerical methods, one of the most popular methods is the alternating direction method of multipliers (ADMM) which was presented originally in [1, 2]. The iterative scheme of ADMM for (2) is as follows:

\[ \begin{align*}
x_1^{k+1} &= \arg \min \left\{ f_1(x_1) - (\lambda^{k})^T A_1 x_1 \\
&\quad + \frac{\beta}{2} \| A_1 x_1 + A_2 x_2^k - b \|^2 \mid x_1 \in X_1 \right\}; \\
x_2^{k+1} &= \arg \min \left\{ f_2(x_2) - (\lambda^{k})^T A_2 x_2 \\
&\quad + \frac{\beta}{2} \| A_1 x_1^{k+1} + A_2 x_2 - b \|^2 \mid x_2 \in X_2 \right\}; \\
\lambda^{k+1} &= \lambda^{k} - \beta \left( A_1 x_1^{k+1} + A_2 x_2^{k+1} - b \right), \\
\end{align*} \tag{3} \]

where \( \lambda^k \) is Lagrange multiplier associated with the linear constraints and \( \beta > 0 \) is the penalty parameter. The convergence of ADMM for (2) was also established under the condition that the involved functions are convex and the constrained sets are convex too.
While there are diversified applications whose objective function is separable into \( m \geq 3 \) individual convex functions without coupled variables, such as traffic problems, the problem of recovering the low-rank, sparse components of matrices from incomplete and noisy observation in [3], the constrained total-variation image restoration and reconstruction problem in [4, 5], and the minimal surface PDE problem in [6], it is thus natural to extend ADMM from 2 blocks to \( m \) blocks, resulting in the iterative scheme:

\[
x_{1}^{k+1} = \arg \min \left\{ f_{1}(x_{1}) - \langle \lambda^{k} \rangle^{T} A_{1} x_{1}ight\} + \frac{\beta}{2} \| A_{1} x_{1} + A_{2} x_{2}^{k} + \cdots + A_{m} x_{m}^{k} - b \|^{2} | x_{1} \in \mathcal{X}_{1} \};
\]

\[
x_{2}^{k+1} = \arg \min \left\{ f_{2}(x_{2}) - \langle \lambda^{k} \rangle^{T} A_{2} x_{2}ight\} + \frac{\beta}{2} \| A_{1} x_{1}^{k+1} + A_{2} x_{2}^{k+1} + \cdots + A_{m} x_{m}^{k} - b \|^{2} | x_{2} \in \mathcal{X}_{2} \};
\]

\vdots

\[
x_{m}^{k+1} = \arg \min \left\{ f_{m}(x_{m}) - \langle \lambda^{k} \rangle^{T} A_{m} x_{m}ight\} + \frac{\beta}{2} \| A_{1} x_{1}^{k+1} + A_{2} x_{2}^{k+1} + \cdots + A_{m} x_{m}^{k+1} - b \|^{2} | x_{m} \in \mathcal{X}_{m} \};
\]

\[
\lambda^{k+1} = \lambda^{k} - \beta \left( A_{1} x_{1}^{k+1} + A_{2} x_{2}^{k+1} + \cdots + A_{m} x_{m}^{k+1} - b \right).
\]

Unfortunately, the convergence of the natural extension is still open under convex assumption, and the recent convergence results [7] are under the assumption that all the functions involved in the objective functions are strongly convex. This lack of convergence has inspired some ADM-based methods, for example, prediction-correction type method [3, 8–11], that is, the iterate \( x_{1}^{k+1}, x_{2}^{k+1}, \ldots, x_{m}^{k+1} \) is regarded as a prediction, and the next iterate is a correction for it. However, the numerical results show that the algorithm (4) always performs better than these variants. Recently, Han and Yuan [7] show that the global convergence of the extension of ADMM for \( m \geq 3 \) is valid if the involved functions are further assumed to be strongly convex. This result does not answer the open problem regarding the convergence of the extension of ADMM under the convex assumption, but it makes a key progress towards this objective.

In this paper, we consider the separable convex optimization problem (1) where each individual function \( f_{i} \) is the combination of a strongly convex function \( g_{i} \) and a linear transform \( B_{i} \). That is, (1) takes the following form:

\[
\min \left\{ \sum_{i=1}^{m} g_{i}(B_{i} x_{i}) \mid \sum_{i=1}^{m} A_{i} x_{i} = b, x_{i} \in \mathcal{X}_{i}, i = 1, 2, \ldots, m \right\},
\]

where \( g_{i} : \mathbb{R}^{n_{i}} \to \mathbb{R} \cup \{+\infty\} (i = 1, 2, \ldots, m) \) are closed proper strongly convex functions with the modulus \( \mu_{i} \) (not necessarily smooth); \( A_{i} \in \mathbb{R}^{l \times n_{i}}, (i = 1, 2, \ldots, m); \mathcal{X}_{i} \subseteq \mathbb{R}^{n_{i}} (i = 1, 2, \ldots, m) \) are closed convex sets; \( b \in \mathbb{R}^{l} \) and \( \sum_{i=1}^{m} n_{i} = n \); \( B_{i} \in \mathbb{R}^{l \times n_{i}}, (i = 1, 2, \ldots, m) \), where \( B_{i} \) may not have full column rank (if \( B_{i} \) has full column rank, the composite function is strongly convex and reduces to the case considered in [7]). Note that although (5) is very special, it arises frequently from many applications. One example is under the route-based traffic assignment problem [12], where \( g_{i} \) is the link traffic cost, \( B_{i} \) is the link-path incidence matrix, and \( x \) is the path follow vector.

In the following, we abuse a little the notation and still write \( g_{i} \) with \( f_{i} \); that is, the problem under consideration is

\[
\min \left\{ \sum_{i=1}^{m} f_{i}(B_{i} x_{i}) \mid \sum_{i=1}^{m} A_{i} x_{i} = b, x_{i} \in \mathcal{X}_{i}, i = 1, 2, \ldots, m \right\},
\]

where \( f_{i} : \mathbb{R}^{n_{i}} \to \mathbb{R} \cup \{+\infty\} (i = 1, 2, \ldots, m) \) are closed proper strongly convex functions with the modulus \( \mu_{i} \) (not necessarily smooth).

The rest of the paper is organized as follows. In the next section, we list some necessary preliminary results that will be used in the rest of the paper. We then describe the algorithm formally and analyze its global convergence under reasonable conditions in Section 3. We complete the paper with some conclusions in Section 4.

2. Preliminaries

In this section, we summarize some basic concepts and their properties that will be useful for further discussion.

Let \( \| \cdot \|_{p} \) denote the standard definition of the \( p \)-norm, and particularly, let \( \| \cdot \| = \| \cdot \|_{2} \) denote the Euclidean norm. For a symmetric and positive definite matrix \( G \), we denote \( \| \cdot \|_{G} \) the \( G \)-norm, that is, \( \| x \|_{G} = \sqrt{x^{T} G x} \). If \( G \) is the product of a positive parameter \( \beta \) and the identity matrix \( I \), that is, \( G = \beta I \), we use the simpler notation: \( \| \cdot \|_{G} = \| \cdot \|_{\beta} \).

Let \( f : \mathbb{R}^{l} \to \mathbb{R} \cup \{+\infty\} \). If the domain of \( f \) denoted by \( \text{dom} \ f = \{ x \in \mathbb{R}^{l} \mid f(x) < +\infty \} \) is not empty, then \( f \) is said to be proper. If for any \( x \in \mathbb{R}^{l} \) and \( y \in \mathbb{R}^{l} \), we have

\[
f \left( (1 - t) x + (1 - t) y \right) \leq t f( x ) + (1 - t ) f ( y), \forall t \in [0, 1],
\]

then \( f \) is said to be convex. Furthermore, \( f \) is said to be strongly convex with the modulus \( \mu > 0 \) if and only if

\[
f \left( (1 - t) x + (1 - t) y \right) \leq t f ( x ) + (1 - t ) f ( y) - \frac{\mu}{2} t (1 - t) \| x - y \|^{2}, \forall t \in [0, 1].
\]
A set-valued operator $T$ defined on $\mathcal{R}^n$ is said to be monotone if and only if
\[(u - \tilde{u})^T (w - \tilde{w}) \geq 0, \quad \forall w \in Tu, \forall \tilde{w} \in T\tilde{u}, \quad (9)\]
and $T$ is said to be strongly monotone with modulus $\mu > 0$ if and only if
\[(u - \tilde{u})^T (w - \tilde{w}) \geq \mu \|u - \tilde{u}\|^2, \quad \forall w \in Tu, \forall \tilde{w} \in T\tilde{u}. \quad (10)\]

Let $\Gamma_0(\mathcal{R}^n)$ denote the set of closed proper convex functions from $\mathcal{R}^n$ to $\mathcal{R} \cup \{+\infty\}$. For any $f \in \Gamma_0(\mathcal{R}^n)$, the subdifferential of $f$ which is the set-valued operator, defined by
\[
\partial f : x \mapsto \left\{ \xi \in \mathcal{R}^n \mid (y - x)^T \xi + f(x) \leq f(y), \forall y \in \text{dom } f \right\},
\]
is monotone. Moreover, if $f$ is strongly convex function with the modulus $\mu$, $\partial f$ is strongly monotone with the modulus $\mu$.

Let $F$ be a mapping from a set $\Omega \subset \mathcal{R}^n$ to $\mathcal{R}^n$. Then $F$ is said to be co-coercive on $\Omega$ with modulus $\gamma > 0$, if
\[(u - v)^T (F(u) - F(v)) \geq \gamma \|F(u) - F(v)\|^2, \quad \forall u, v \in \Omega. \quad (12)\]

Throughout the paper, we make the following assumptions.

**Assumption 1.** (i) $n_i \|B_i x_i\| \geq \|A_i x_i\|, \forall x_i \in \mathcal{R}^n$, $i \in \{1, 2, \ldots, m\}$; (ii) the solution set of (1) is nonempty.

**Remark 2.** Assumption 1 is a little restrictive. However, some problems can satisfy it. A remarkable one is the following route-based traffic assignment problem.

Consider a transportation network $G(\mathcal{N}, E)$, where $\mathcal{N}$ is the set of nodes. We denote the set of links by $\mathcal{A}$, and the number of the element of $\mathcal{A}$ by $N_{\mathcal{A}}$, respectively. Let RS denote the set of origin-destination (O-D) pairs. For an O-D pair $rs \in \text{RS}$, let $q_{rs}^s$ be its traffic demand; let $P^r$ be the set of routes connecting $rs$, and $p \in P^r$; $N^r$ denotes the number of the routes connecting $rs$; let $h_{rs}^p$ be the route flow on $p$. The feasible route flow vector $h = (p \in P^r \mid rs \in \text{RS})$ is thus given by

\[
H = \left\{ h \mid \sum_{p \in P^r} h_{rs}^p = q_{rs}^s, h_{rs}^p \geq 0, \forall p \in P^r, rs \in \text{RS} \right\}.
\]

Define $E$ as the link-route incidence matrix such that
\[
\delta_{rp}^s = \begin{cases} 1, & \text{if } p \text{ contains link } a \\ 0, & \text{otherwise.} \end{cases}
\]

Then, link flow $f_a$ can be written as
\[
f_a = \sum_{rs \in \text{T}_a} \sum_{p \in P^r} \delta_{rp}^s h_{rs}^p, \quad \forall a \in \mathcal{A},
\]

(15)

By denoting the link cost function as $C_a(f)$ and for the additive case, the route cost function as $C_p(h)$, they can be related by
\[
C_p h = \sum_{a \in \mathcal{A}} \delta_{rp}^s C_a (f).
\]

The user equilibrium traffic assignment problem can be formulated as a VI: find $f^* \in F$ such that
\[
(f - f^*)^T C (f^*) \geq 0, \quad \forall f \in F,
\]

(17)
or equivalently, find $h^* \in H$ such that
\[
(h - h^*)^T E^T C(\text{Eh}^*) \geq 0, \quad \forall h \in H,
\]

(18)

where $C = \{C_a\}$ is the vector of the link cost function.

In general, it is easy to show that $e$ is a row of $E$ and $E$ is not a full column rank (if $E$ is, then the above variational inequality is strongly monotone).

For simplicity, in the following, we only consider the case for $m = 3$. Notice that for $m \geq 3$, it can be proved similarly following the processing of $m = 3$.

### 3. The Method

In this section, we consider the following convex minimization problem with linear constraint, where the objective function is in the form of the sum of three individual functions without coupled variable:

\[
\min \ f_1(B_1 x_1) + f_2(B_2 x_2) + f_3(B_3 x_3)
\]

s.t. $A_1 x_1 + A_2 x_2 + A_3 x_3 = b, \quad x_i \in \mathcal{X}_i, \quad i = 1, 2, 3,
\]

(19)

where $f_i : \mathcal{R}^{n_i} \rightarrow \mathcal{R} \cup \{+\infty\} (i = 1, 2, 3)$ are closed proper strongly convex function with the modulus $\mu_i$ (not necessarily smooth); $B_i \in \mathcal{R}^{k_i n_i}, (i = 1, 2, 3)$, $A_i \in \mathcal{R}^{k_i n_i}, (i = 1, 2, 3)$; $\mathcal{X}_i \subseteq \mathcal{R}^{n_i}, (i = 1, 2, 3)$ are closed convex sets; $b \in \mathcal{R}^l$ and $\sum_{i=1}^3 n_i = n$. 
The iterative scheme of ADMM for problem (19) is as follows:

\[ x_1^{k+1} = \arg\min \left\{ f_1(B_1 x_1) - (\lambda^k)^T A_1 x_1 + \frac{\beta}{2} \left\| A_1 x_1 \right\|^2 + A_2 x_2^k + A_3 x_3^k - b \right\| \mid x_1 \in \mathcal{X}_1 \}, \]

\[ x_2^{k+1} = \arg\min \left\{ f_2(B_2 x_2) - (\lambda^k)^T A_2 x_2 + \frac{\beta}{2} \left\| A_2 x_2 \right\|^2 + A_3 x_3^k - b \right\| \mid x_2 \in \mathcal{X}_2 \}, \]

\[ x_3^{k+1} = \arg\min \left\{ f_3(B_3 x_3) - (\lambda^k)^T A_3 x_3 + \frac{\beta}{2} \left\| A_3 x_3 \right\|^2 + A_2 x_2^k + A_3 x_3^k - b \right\| \mid x_3 \in \mathcal{X}_3 \}, \]

\[ \lambda^{k+1} = \lambda^k - \beta \left( A_1 x_1^{k+1} + A_2 x_2^{k+1} + A_3 x_3^{k+1} - b \right), \]

where \( \lambda^k \) is the Lagrangian multiplier associated with the linear constraints and \( \beta > 0 \) is the penalty parameter.

4. Convergence

In this section, we prove the convergence of the extended ADMM for problem (19). As the assumptions aforementioned, by invoking the first-order necessary and sufficient condition for convex programming, we easily see that the problem (19) under the condition is characterized by the following variational inequality (VI): find \( u^* \in \mathcal{U} \) and \( \xi_i^* \in \partial f_i(B_i x_i^*) \) such that

\[ (u - u^*)^T Q(u) \geq 0, \quad \forall u \in \mathcal{U}, \tag{21} \]

where

\[ u := \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ \lambda \end{pmatrix}, \quad Q(u) := \begin{pmatrix} B_1^T \xi_1 - A_1^T \lambda \\ B_2^T \xi_2 - A_2^T \lambda \\ B_3^T \xi_3 - A_3^T \lambda \\ A_1 x_1 + A_2 x_2 + A_3 x_3 - b \end{pmatrix}, \]

\[ \mathcal{U} = \mathcal{X}_1 \times \mathcal{X}_2 \times \mathcal{X}_3 \times \mathcal{X}_1^T. \tag{22} \]

We denote the VI (21)–(22) by MVI(\( \mathcal{U}, Q \)).

Similarly, in [7], we propose an easily implementable stopping criterion for executing (20):

\[ \max \left\{ \max_{i=1}^{3} \left\| A_i x_i^k - A_i x_i^{k+1} \right\|, \sum_{i=1}^{3} \left\| A_i x_i^k - b \right\| \right\} \leq \epsilon, \tag{23} \]

and its rationale can be seen in the following lemma.

**Lemma 3** (see [7]). If \( \sum_{i=1}^{3} A_i x_i^k - b = 0 \) and \( A_i x_i^k = A_i x_i^{k+1} \) (\( i = 1, 2, 3 \)), then \( (x_1^{k+1}, x_2^{k+1}, x_3^{k+1}, \lambda^{k+1}) \) is a solution of MVI(\( \mathcal{U}, Q \)).

**Lemma 3** implies that the iterate \{\( (x_1^k, x_2^k, x_3^k, \lambda^k) \)\} is a solution of MVI(\( \mathcal{U}, Q \)) when the inequality (23) holds with \( \epsilon = 0 \). Some techniques of establishing the error bounds in [13] can help us analyze how precisely the iterate satisfies the optimality conditions when the proposed stopping criterion is satisfied with a tolerance \( \epsilon > 0 \).

**Lemma 4.** Let \( (x_1^k, x_2^k, x_3^k, \lambda^k) \) be the solution of the problem (19), and let \( \lambda^* \) be a corresponding Lagrange multiplier associated with the linear constraint. Then, the sequence \{\( (x_1^k, x_2^k, x_3^k, \lambda^k) \)\} generated by (20) satisfies

\[ (\lambda^k - \lambda^*)^T \left( \sum_{i=1}^{3} A_i x_i^{k+1} - b \right) \]

\[ \geq \sum_{i=1}^{3} (x_i^{k+1} - x_i^*)^T (B_i^T \xi_i^{k+1} - B_i^T \xi_i^*) \]

\[ + \beta \left\| \sum_{i=1}^{3} A_i x_i^{k+1} - b \right\|^2 + \beta (A_1 x_1^{k+1} - A_1 x_1^*)^T \]

\[ \times \left[ A_2 x_2^k - A_2 x_2^{k+1} + (A_3 x_3^k - A_3 x_3^{k+1}) \right] \]

\[ + \beta (A_2 x_2^{k+1} - A_2 x_2^*)^T (A_3 x_3^k - A_3 x_3^{k+1})]. \tag{24} \]

**Proof.** By invoking the first-order optimality condition for the \( x_i^{k+1} \)-related subproblem in (20), for any \( x_i \in \mathcal{X}_i, i = 1, 2, 3 \), we get

\[ (x_i - x_i^{k+1})^T \{ B_i^T \xi_i^{k+1} \}

\[ - A_i^T [\lambda^k - \beta (A_1 x_1^{k+1} + A_2 x_2^k + A_3 x_3^k - b)] \}

\[ \geq 0, \]

\[ (x_i - x_i^{k+1})^T \{ B_i^T \xi_i^{k+1} - A_i^T \}

\[ \times [\lambda^k - \beta (A_1 x_1^{k+1} + A_2 x_2^{k+1} + A_3 x_3^k - b)] \}

\[ \geq 0, \]
Setting $x_1 = x_1^*$ ($i = 1, 2, 3$) in (25), we have

\[
(x_1^* - x_1^{k+1})^T \{ B_1^T \xi_1^{k+1} - A_1^T \}
- A_1^T \left[ \lambda^k - \beta \left( A_1 x_1^{k+1} + A_2 x_2^{k+1} + A_3 x_3^{k+1} - b \right) \right] \geq 0,
\]

(25)

On the other hand, setting $(x_1, x_2, x_3) = (x_1^{k+1}, x_2^{k+1}, x_3^{k+1})$ in (21), it follows that

\[
\begin{pmatrix} x_1^{k+1} - x_1^* \\ x_2^{k+1} - x_2^* \\ x_3^{k+1} - x_3^* \end{pmatrix}^T \begin{pmatrix} B_1^T \xi_1^{k+1} - A_1^T \lambda^* \\ B_2^T \xi_2^{k+1} - A_2^T \lambda^* \\ B_3^T \xi_3^{k+1} - A_3^T \lambda^* \end{pmatrix} \geq 0.
\]

(27)

Adding (26) and (27), we obtain

\[
(x_1^{k+1} - x_1^*) \frac{B_1^T \xi_1^{k+1} - A_1^T \lambda^*}{(B_2^T \xi_2^{k+1} - A_2^T \lambda^*)}(B_3^T \xi_3^{k+1} - A_3^T \lambda^*) \geq 0.
\]

(28)

With the rearrangement of the above inequalities, we derive that

\[
(x_1^{k+1} - x_1^*)^T A_1^T \left( \lambda^k - \lambda^* \right)
\geq (x_1^{k+1} - x_1^*)^T \left( B_1^T \xi_1^{k+1} - B_1^T \lambda^* \right)
+ \beta (A_1 x_1^{k+1} - A_1 x_1^*)^T \left( \sum_{i=1}^3 A_i x_i^{k+1} - b \right)
\]

(29)

Adding the above inequalities (29), we have

\[
(\lambda^k - \lambda^*)^T \left( \sum_{i=1}^3 A_i x_i^{k+1} - b \right)
\geq \sum_{i=1}^3 (x_i^{k+1} - x_i^*)^T \left( B_i^T \xi_i^{k+1} - B_i^T \lambda^* \right)
+ \beta (A_1 x_1^{k+1} - A_1 x_1^*)^T \left[ (A_2 x_2^{k+1} - A_2 x_2^*) + (A_3 x_3^{k+1} - A_3 x_3^*) \right]
+ \beta (A_2 x_2^{k+1} - A_2 x_2^*)^T (A_3 x_3^{k+1} - A_3 x_3^*)
\]

(30)

The proof is complete. \qed

Hereafter, we define a matrix which will make the notation of proof more succinct. More specifically, let

\[
M = \begin{pmatrix} 2 \beta A_1^T A_1 & 0 & 0 & 0 \\ 0 & 2 \beta A_2^T A_2 & 0 & 0 \\ 0 & 0 & 2 \beta A_3^T A_3 & 0 \\ 0 & 0 & 0 & \frac{1}{\beta} I \end{pmatrix}.
\]

(31)
Obviously, $M$ is a positive semidefinite matrix, only for analysis convenience; we denote

$$\|u\|_M^2 = 2\beta \left( \|A_1x_1\|^2 + \|A_2x_2\|^2 + \|A_3x_3\|^2 \right) + \|\lambda\|_{1/\beta}^2.$$  

(32)

**Lemma 5.** Let $u^* = (x_1^*, x_2^*, x_3^*, \lambda^*)$ be a solution of $\text{MVH}(\mathcal{U}, Q)$, and let the sequence $\{(x_1^k, x_2^k, x_3^k, \lambda^k)\}$ be generated by (20). Then, one has

$$\|u^{k+1} - u^*\|_M^2 \leq \|u^k - u^*\|_M^2 + \sum_{i=1}^3 3\beta \|A_i x_i^{k+1} - A_i x_i^*\|^2$$

$$- 2 \sum_{i=1}^3 \mu_i \|B_i x_i^{k+1} - B_i x_i^*\|^2.$$  

(33)

**Proof.** From (20) and Lemma 4, we have

$$\|\lambda^{k+1} - \lambda^*\|_{1/\beta}^2 = \|\lambda^k - \lambda^* - \beta \left( \sum_{i=1}^3 A_i x_i^{k+1} - b \right)\|^2_{1/\beta}$$

$$= \|\lambda^k - \lambda^*\|^2_{1/\beta}$$

$$- 2 (\lambda^k - \lambda^*)^T \left( \sum_{i=1}^3 A_i x_i^{k+1} - b \right)$$

$$+ \beta \left( \sum_{i=1}^3 A_i x_i^{k+1} - b \right)^2$$

$$\leq \|\lambda^k - \lambda^*\|^2_{1/\beta}$$

$$- 2 \sum_{i=1}^3 (x_i^{k+1} - x_i^*)^T (B_i^T x_i^{k+1} - B_i^T x_i^*)$$

$$- 2 \beta \|A_i x_i^{k+1} - A_i x_i^*\|^2$$

$$\sum_{i=1}^3 (A_i x_i^{k} - A_i x_i^{k+1})$$

$$- 2 \beta (A_1 x_1^{k+1} - A_1 x_1^*)^T (A_3 x_3^k - A_3 x_3^{k+1}).$$  

(34)

Using Cauchy-Schwarz inequality, we have

$$- 2 \beta (A_1 x_1^{k+1} - A_1 x_1^*)^T \left( \sum_{i=2}^3 (A_i x_i^k - A_i x_i^{k+1}) \right)$$

$$- 2 \beta (A_1 x_1^{k+1} - A_1 x_1^*)^T (A_3 x_3^k - A_3 x_3^{k+1})$$

$$= -2 \beta (A_1 x_1^{k+1} - A_1 x_1^*)^T (A_3 x_3^k - A_3 x_3^{k+1})$$

$$+ 2 \beta (A_3 x_3^{k+1} - A_3 x_3^k)^T (A_3 x_3^k - A_3 x_3^{k+1})$$

$$+ 2 \beta (A_2 x_2^{k+1} - A_2 x_2^k)^T (A_3 x_3^k - A_3 x_3^{k+1})$$

$$\leq 2 \beta \|A_1 x_1^{k+1} - A_1 x_1^*\|^2 + \beta \|A_2 x_2^{k+1} - A_2 x_2^k\|^2$$

$$+ 2 \beta (x_2^k - x_2^*)^2 + 2 \beta (x_3^k - x_3^*)^2$$

$$+ \beta \sum_{i \neq j} (A_i (x_i^{k+1} - x_i^*))^T A_j (x_j^{k+1} - x_j^*).$$  

(37)
Substituting (36) and (37) into (34), we get

\[ \| \lambda^{k+1} - \lambda^* \|_{1/\beta}^2 \leq \| \lambda^k - \lambda^* \|_{1/\beta}^2 + 2 \beta \sum_{i=1}^3 \left\| A_i (x^{k+1}_i - x^*_i) \right\|^2 + 2 \beta \sum_{i=1}^3 \left\| A_i (x^*_i - x^*_i) \right\|^2 - 2 \sum_{i=1}^3 \left\| x^{k+1}_i - x^*_i \right\| B_i^T (\xi^{k+1}_i - B_i x^*_i) \].

(38)

Since \( f_i \) is strongly convex, from the strong monotonicity of the subdifferential mapping \( \partial f_i \) (with the modulus \( \mu_i \)), then we have

\[ \left( x^{k+1}_i - x^*_i \right)^T \left( B_i^T (\xi^{k+1}_i - B_i x^*_i) \right) = \left( B_i x^{k+1}_i - B_i x^*_i \right)^T (\xi^{k+1}_i - x^*_i) \geq \mu_i \left\| B_i x^{k+1}_i - B_i x^*_i \right\|^2, \]  

(39)

where \( \xi^*_i \in \partial f_i(B_i x^*_i), \xi^{k+1}_i \in \partial f_i(B_i x^{k+1}_i) \), for any \( i \in \{1, 2, 3\} \).

By using the notion of \( \| u^{k+1} - u^* \|_M \), from (38) we have

\[ \| u^{k+1} - u^* \|^2_M \]

\[ = \| \lambda^{k+1} - \lambda^* \|^2_{1/\beta} + 2 \beta \sum_{i=1}^3 \left\| A_i (x^{k+1}_i - x^*_i) \right\|^2 - 2 \sum_{i=1}^3 \left\| x^{k+1}_i - x^*_i \right\| B_i^T (\xi^{k+1}_i - B_i x^*_i) \]

\[ \leq \| \lambda^k - \lambda^* \|^2_{1/\beta} + 2 \beta \sum_{i=1}^3 \left\| A_i (x^*_i - x^*_i) \right\|^2 - 2 \sum_{i=1}^3 \left\| x^{k+1}_i - x^*_i \right\| B_i^T (\xi^{k+1}_i - B_i x^*_i) \]

\[ \leq \| u^k - u^* \|^2_M + 2 \beta \sum_{i=1}^3 \left\| A_i x^{k+1}_i - A_i x^*_i \right\|^2 - 2 \sum_{i=1}^3 \left\| x^{k+1}_i - x^*_i \right\| B_i^T (\xi^{k+1}_i - B_i x^*_i) \]

\[ - 2 \sum_{i=1}^3 \left\| x^{k+1}_i - x^*_i \right\| B_i^T (\xi^{k+1}_i - B_i x^*_i) \].

(40)

The proof is complete.

**Theorem 6.** Under Assumption 1, for any

\[ 0 < \beta < \min_{1 \leq i \leq 3} \left\{ \frac{2 \mu_i}{3 m_i^2} \right\}, \]  

(41)

the sequence \( \{x^{k}_1,x^{k}_2,x^{k}_3,\lambda^{k}\} \) generated by (20) converges to a solution of MVI(\( \mathcal{U}, Q) \).

**Proof.** From Lemma 5, we have

\[ \| u^{k+1} - u^* \|^2_M \leq \| u^k - u^* \|^2_M + 3 \beta \sum_{i=1}^3 \left\| A_i x^{k+1}_i - A_i x^*_i \right\|^2 - 2 \sum_{i=1}^3 \left\| x^{k+1}_i - x^*_i \right\| B_i^T (\xi^{k+1}_i - B_i x^*_i) \].

(42)

\[ \| u^{k+1} - u^* \|^2_M \leq \| u^k - u^* \|^2_M + 3 \beta \sum_{i=1}^3 \left\| A_i x^{k+1}_i - A_i x^*_i \right\|^2 - 2 \sum_{i=1}^3 \left\| x^{k+1}_i - x^*_i \right\| B_i^T (\xi^{k+1}_i - B_i x^*_i) \].

(43)

From Assumption 1, it follows that

\[ \| A_i x^{k+1}_i - A_i x^*_i \|^2 \leq \| A_i x^*_i - x^*_i \|^2 \]

\[ \leq \mu_i^2 \| B_i x^{k+1}_i - B_i x^*_i \|^2, \quad i = 1, 2, 3. \]  

(44)

Consequently,

\[ \| u^{k+1} - u^* \|^2_M \leq \| u^k - u^* \|^2_M + 3 \beta \sum_{i=1}^3 \left( 3 \beta - \frac{2 \mu_i}{m_i^2} \right) \left\| A_i x^{k+1}_i - A_i x^*_i \right\|^2. \]  

(45)

From (45), we have

\[ \| u^{k+1} - u^* \|^2_M \leq \| u^k - u^* \|^2_M \leq \cdots \leq \| u^0 - u^* \|^2_M < +\infty, \]  

(46)

which means that the generated sequence \( \{u^k\} \) is bounded. Furthermore, it follows that

\[ \sum_{k=0}^{+\infty} \left\{ 3 \beta \sum_{i=1}^3 \left( \frac{2 \mu_i}{m_i^2} - 3 \beta \right) \left\| A_i x^{k+1}_i - A_i x^*_i \right\|^2 \right\} \]

\[ \leq \sum_{k=0}^{+\infty} \left\{ \| u^k - u^* \|^2_M - \| u^{k+1} - u^* \|^2_M \right\} < +\infty, \]  

(47)

which means that

\[ \lim_{k \to +\infty} \sum_{i=1}^3 \left\| A_i x^{k+1}_i - A_i x^*_i \right\|^2 = 0. \]  

(48)

Therefore, we have

\[ \lim_{k \to +\infty} \left\| \sum_{i=1}^3 A_i x^{k+1}_i - b \right\|^2 = 0. \]  

(49)

Since \( \| A_i \| \) is nonzero and bounded, from (48) we have

\[ \lim_{k \to +\infty} \left\| x^{k+1}_i - x^*_i \right\| = 0, \quad \forall i \in \{1, 2, 3\}. \]  

(50)

Since \( \{u^k\} \) is bounded, \( \{x^k\} \) has at least one cluster point, say \( \overline{x} \). Let \( \{\lambda^k\} \) be the corresponding subsequence that converges...
to $\overline{\lambda}$. Taking a limit along this subsequence in (25) and (49), we obtain $\xi_i^* \in \partial f_i(B_i x_i^*)$,

$$(x_i - x_i^*)^T (B_i^T \xi_i^* - A_i^T \overline{\lambda}) \geq 0, \quad \forall x_i \in \mathcal{X}_i, \ i = 1, 2, 3,$$

$$\sum_{i=1}^{3} A_i x_i^* - b = 0,$$

which follows that $\overline{\lambda}$ is an optimal Lagrange multiplier. Since $\lambda^*$ is arbitrary, we can set $\lambda^* = \overline{\lambda}$ in (46) and conclude that the whole generated sequence converges to a solution of MVI($\mathcal{X}, Q$).

5. Conclusions

In this paper, we extend the convergence analysis of the ADMM for the separable convex optimization problem with strongly convex functions to the case in which the individual functions are composites of strongly convex functions with a linear transform. Under further assumptions, we established the global convergence of the algorithm.

It should be admitted that although some problems arising from applications such as traffic assignment fall into our analysis, the problems considered here are too special. Thus, it is far away to solve the open problem of convergence of the ADMM with more than three blocks.

We present an efficient method for solving linearly constrained convex programming. Our algorithmic framework employs an implementable proximal step by a slight relaxation to the subproblem of proximal point algorithm (PPA). In particular, the stepsize choice condition of our algorithm is weaker than some elegant PPA-type methods. This condition is flexible and effective. Self-adaptive strategies are proposed to improve the convergence in practice. We theoretically show under mild conditions that our method converges in a global sense. Finally, we discuss applications and perform numerical experiments which confirm the efficiency of the proposed method. Comparisons of our method with some state-of-the-art algorithms are also provided.

1. Introduction

In this paper, we consider the following generic convex programming:

\[ \min \{ \theta(x) \mid Ax = b \ (or \ Ax \geq b), x \in \mathcal{X} \}, \tag{1} \]

where \( \theta(x) : \mathbb{R}^n \rightarrow \mathbb{R} \) is a convex (not necessary smooth) function, \( A \in \mathbb{R}^{m \times n} \), \( b \in \mathbb{R}^m \), and \( \mathcal{X} \subset \mathbb{R}^n \) is a closed convex set. Problem (1) generalizes a wide range of problems that frequently arise in signal and image processing and reconstruction, mechanics, statistics, operations research, and other fields, for example, basis pursuit [1–4], nearest correlation matrix [5–7], matrix completion problem [2, 3, 8–10], and so forth. Before we begin, some assumptions should be presented for problem (1).

Assumption 1. The solution set of (1) is denoted by \( \mathcal{X}^* \), and it is assumed to be nonempty.

Assumption 2. The objective function is simple. This means that, for a given constant \( \vartheta \), the following proximal problem admits a closed-form solution or can be solved efficiently with high precision:

\[ \min_{x \in \mathcal{X}} \theta(x) + \frac{\vartheta}{2} \| x - a \|^2, \tag{2} \]

where \( a \) is any given vector. At first sight, this assumption seems to be quite restrictive, but this is indeed for many problems in practice. For example, nuclear norm function in matrix completion problem, \( l_1 \)-norm function in basis pursuit problem, and so forth.

Many fundamental methods have been developed over the past decades to solve problem (1). Proximal point algorithm (PPA) is one of the leading approaches for solving convex optimization problems. It is earlier used for regularized linear equations and has been applied to convex optimization by Martinet [11]. There are some significant theoretical achievements [12–19] in the field of PPA for convex optimization and monotone variational inequalities (VIs). Nowadays, it is still the object of intensive investigation [20] and leads to a variety of primal and dual methods. Common to PPA and its variants is the difficulty of their subproblems; this restricts the practical interest. Augmented Lagrangian method (ALM) [21] is a powerful method for linearly constrained problems. It can be regarded as a variant of PPA applied to the dual problem of (1). However, with the additional regularized term \( \| Ax - b \|^2 \), its subproblems require an inverse operator of the form \((I + (1/s)A^TA)^{-1}\) which is hard to implement in some cases. Particularly, \( A^TA \) is general or large scale, so the computation of inverse operator may fail. Hence,
A practical method for solving (1) which employs the information of current iteration. In fact, EGM is an explicit type method and requires two calls to the gradient per iteration; therefore, it might suffer slow convergence. Recently, He and Yuan [23] proposed a contraction method based on PPA (PPA-CM) to solve (1), which is elegant and simple. Inspired by PPA-CM, a Lagrangian PPA-based (LPPA) contraction method is presented in [24] which employs an asymmetrical proximal term [25]. These two PPA-based methods have nice convergence properties that are similar in many ways to PPA, but they both require a quite restrictive condition for convergence and are sensitive to the initial choice of stepsizes.

In this section, we first establish some important notations and preliminaries which are useful for subsequent analysis. In Section 3, we review some related works. The general relaxed-PPA and its variant are formally presented in Section 4. Self-adaptive strategies to choose stepsize are also described. Next, in Section 5, the convergence analysis is provided. In Section 6, we present some concrete applications of (1) and elaborate on the implementation of our method; preliminary numerical results are also reported to verify the efficiency of our proposed method. Finally, in Section 7, we conclude the paper with a discussion about the future research directions.

2. Preliminaries

In this section, we first establish some important notations used throughout this paper. Then, we describe the variational inequality formulation of (1) which is convenient for the convergence analysis.

\( \partial \theta(x) \) denotes the subdifferential set of the convex function \( \theta(x) \):

\[
\partial \theta(x) := \{ d \in \mathbb{R}^n \mid \theta(y) - \theta(x) \geq d^T (y-x), \forall y \in \mathbb{R}^n \}, \tag{3}
\]

and \( d \in \partial \theta(x) \) is called a subgradient of \( \theta(x) \), see [26]. Let \( f(x) \in \partial \theta(x) \) and \( f(y) \in \partial \theta(y) \), by the convexity of the function \( \theta \), we have

\[
(x - y)^T (f(x) - f(y)) \geq 0, \quad \forall x, y \in \mathbb{R}^n, \tag{4}
\]

which indicates that the mapping \( f \) is monotone.

Now, we show that (1) can be characterized by a variational inequality; see, for example, [27]. By attaching a Lagrange multiplier vector \( \lambda \in \Lambda \) to the linear constraint \( Ax = b \) (or \( Ax \geq b \)), the Lagrangian function of (1) is

\[
L(x, \lambda) = \theta(x) - \lambda^T (Ax - b); \tag{5}
\]

here,

\[
\Lambda = \begin{cases} \mathbb{R}^m, & \text{for the equality constraints } Ax = b, \\ \mathbb{R}^m_+, & \text{for the inequality constraints } Ax \geq b, \end{cases} \tag{6}
\]

and \( L(x, \lambda) \) is defined on \( \mathcal{X} \times \Lambda \). Then, by the optimality condition, we can easily see that (1) amounts to finding a pair of \((x^*, \lambda^*)\) which satisfies

\[
x^* \in \mathcal{X}, \quad (x - x^*)^T \{ f(x^*) - A^T \lambda^* \} \geq 0, \quad \forall x \in \mathcal{X}, \tag{7}
\]

\[
\lambda^* \in \Lambda, \quad (\lambda - \lambda^*)^T (Ax^* - b) \geq 0, \quad \forall \lambda \in \Lambda,
\]

where \( f(x^*) \in \partial \theta(x^*) \). Denoting

\[
u = \begin{pmatrix} x \\ \lambda \end{pmatrix}, \quad F(u) = \begin{pmatrix} f(x) - A^T \lambda \\ Ax - b \end{pmatrix}, \quad \Omega = \mathcal{X} \times \Lambda,
\]

the system (7) can be characterized by the following variational inequality denoted by \( VI(\mathcal{X}, F) \):

\[
u^* \in \Omega, \quad (\nu - \nu^*)^T F(\nu^*) \geq 0, \quad \forall \nu \in \Omega. \tag{9}
\]

Recalling the monotonicity of \( f \), it is easy to get that \( VI(\mathcal{X}, F) \) (9) is monotone. Since the solution set of (1) is assumed to be nonempty, the solution set of \( VI(\mathcal{X}, F) \), denoted by \( \Omega^* \), is also nonempty. Our analysis will be built upon this equivalent VI formulation.

3. The Existing Related Methods

There are basically two lines of research for \( VI(\mathcal{X}, F) \) (9), either deal with it by implicit methods that are in general computationally intractable or concentrate on relaxing it with explicit methods. In this section, we first briefly review the well-known classical PPA and EGM. And then, PPA-CM [23] and LPPA [24] are discussed, which will provide motivation for our general self-adaptive relaxed-PPA.

3.1. Classical PPA for the Equivalent Variational Inequality

PPA and its variants are implicit methods which have fast asymptotical convergence rate and produce highly accurate solutions. At each iteration, the subproblem of classical PPA consists of a regularized term, which can be expressed as
follows: given any iterate $u^k = (x^k, \lambda^k)$, find $\tilde{u}^k = (\tilde{x}^k, \tilde{\lambda}^k) \in \Omega$ such that
\[ u^k \in \Omega, \quad (u - \tilde{u})^T \left\{ F(u^k) + r(\tilde{u}^k - u^k) \right\} \geq 0, \quad \forall u \in \Omega. \] (10)

Then, the update step is taken as follows:
\[ u^{k+1} = u^k - \gamma (u^k - \tilde{u}^k), \quad \gamma \in (0, 2). \] (11)

PPA has a nice convergence property
\[ \| u^{k+1} - u^* \|^2 \leq \| u^k - u^* \|^2 - \gamma (2 - \gamma) \| u^k - \tilde{u}^k \|^2. \] (12)

Although classical PPA is conceptually appealing, subproblem (10) presents certain computational challenges. More specifically, primal variable $x$ and dual variable $\lambda$ are tied together, and their subproblems are treated as a joint problem. In most cases, this joint subproblem may be as difficult as the original problem (9). As a result, PPA is “conceptual” rather than implementable. It lacks capability in exploiting potential decomposable/specific structure of subproblem. Variants of classical PPA have been explored in the literature, in order to solve the proximal subproblem (10), inexactly, see, for example, [14, 15, 17, 19]. Unfortunately, inexact variants take expensive computation for obtaining approximative solutions.

3.2. The Methods Based on the Simplest Relaxation. To overcome the drawbacks of the classical PPA, it is instinctive to relax subproblem (10) to a solvable one. The most straightforward and simplest relaxation is to replace $F(u^k)$ with $F(\tilde{u}^k)$ in the proximal subproblem (10), which amounts to the following subproblem:
\[ \tilde{u}^k \in \Omega, \quad (u - \tilde{u})^T \left\{ F(\tilde{u}^k) + r(\tilde{u}^k - u^k) \right\} \geq 0, \quad \forall u \in \Omega. \] (13)

The solution of the relaxed problem (13) is given by $\tilde{u}^k = P_\Omega[u^k - (1/r)F(\tilde{u}^k)]$. It is clear that methods with such relaxation are explicit type methods. However, $\tilde{u}^k$ cannot be accepted directly as the new iterate. Using the terminology “predictor-corrector,” such point can be viewed as a predictor. Here, we list two simple methods which employ predictor $\tilde{u}^k$ to obtain corrector as the new iterate.

(i) The extragradient method (EGM) updates the new iterate (corrector) by
\[ u^{k+1} = P_\Omega \left[ u^k - \frac{1}{r} F(\tilde{u}^k) \right]. \] (14)

(ii) The projection and contraction methods (PCM) [28–30] perform update as follows:
\[ u^{k+1} = u^k - \gamma \alpha_k ^* \tilde{u}^k \quad \text{or} \quad u^{k+1} = P_\Omega \left[ u^k - \frac{\gamma \alpha_k ^*}{r} F(\tilde{u}^k) \right], \] (15)

where
\[ d^k = (u^k - \tilde{u}^k) - \frac{1}{r} \left( F(u^k) - F(\tilde{u}^k) \right), \]
\[ \alpha_k ^* = \frac{(u^k - \tilde{u}^k)^T d^k}{\|d^k\|^2}. \] (16)

The sequence $\{ u^k \}$ generated by the above mentioned EGM or PCM satisfies
\[ \| u^{k+1} - u^* \|^2 \leq \| u^k - u^* \|^2 - c \| u^k - \tilde{u}^k \|^2, \quad c > 0, \] (17)

which is similar to PPA. Both EGM and PCM use the simplest relaxation to obtain $\tilde{u}^k$ in $k$th iteration, hence are computationally practical. These methods have appealing practical aspects; however, such simplest relaxation does not exploit the inner structure of VI$(\Omega, F)$ (9). This observation prompts the need for dedicated relaxations.

3.3. PPA-Type Contraction Method. The algorithms that are closely related to ours are PPA-CM [23] and LPPA [24]. The PPA-CM obtains the predictor $\tilde{u}^k$ by solving the following subproblem: find $(\tilde{x}^k, \tilde{\lambda}^k) \in \Omega$ such that
\[ \tilde{u}^k \in \Omega, \quad (u - \tilde{u})^T \left\{ F(\tilde{u}^k) + S(\tilde{u}^k - u^k) \right\} \geq 0, \quad \forall u \in \Omega, \] (18)

where
\[ S = \begin{bmatrix} r I_n & -A^T \\ -A & s I_m \end{bmatrix}. \] (19)

And perform the update
\[ u^{k+1} = u^k - \gamma (u^k - \tilde{u}^k), \quad \gamma \in (0, 2). \] (20)

The framework of LPPA is as follows:
\[ u^k \in \Omega, \quad (u - \tilde{u})^T \left\{ F(\tilde{u}^k) + M(\tilde{u}^k - u^k) \right\} \geq 0, \quad \forall u \in \Omega, \] (21)

where
\[ M = \begin{bmatrix} r I_n & A^T \\ 0 & s I_m \end{bmatrix}. \] (22)

And the new iterate is defined by
\[ u^{k+1} = u^k - \gamma \alpha M (u^k - \tilde{u}^k), \quad \gamma \in (0, 2). \] (23)

Both procedures are simple and can solve subproblem efficiently; but their nice convergence results require a quite restrictive condition, that is; $rs > \| A^T A \|$ in PPA-CM and $rs > (1/2) \| A^T A \|$ in LPPA, respectively. The stepsizes $r,s$ are directly determined by such condition; hence, it is important to estimate $\| A^T A \|$. Overestimation may lead to poor stepsizes and slow convergence, while underestimation may result in divergence. In addition, they are both quite sensitive to the choice of $r,s$. To overcome these drawbacks, we propose a general self-adaptive relaxed-PPA, and as mentioned earlier, it can provide improved guarantee for convergence and has potential progress in the choice of stepsizes. Furthermore, self-adaptive strategies are designed to improve performance.
**Step 1. Initialization.** Let \( \gamma \in (0, 2) \) and pick \((x^0, \lambda^0) \in \mathbb{R}^n \times \Lambda\), set \( k = 0 \).

**Step 2. Predictor.** Let
\[
\hat{x}^k = \text{Argmin} \left\{ \theta(x) + \frac{r}{2} \| x - \left[ x^k + \frac{1}{r} \Lambda^T \lambda^k \right] \|^2 \mid x \in \mathcal{X} \right\},
\]
and
\[
\hat{\lambda}^k = P_{\Lambda} \left[ \lambda^k - \frac{1}{s} (A^T \hat{x}^k - b) \right].
\]

**Step 3.** If the stepsize \( r \) is chosen satisfying
\[
\varphi(u^k, \hat{u}^k) \geq \frac{1}{4} \| d(u^k, \hat{u}^k) \|^2_{G},
\]
then go to Step 4. Otherwise, increase \( r, s \) and go back to Step 2.

**Step 4. Corrector and updating**
\[
u^{k+1} = u^k - \alpha_k G^{-1} M(u^k - \hat{u}^k).
\]

**Step 5. Adjustment**
\[
(r, s) = \begin{cases} 
\left( \frac{r}{2}, \frac{s}{2} \right), & \text{if } \varphi(u^k, \hat{u}^k) \geq \kappa \cdot \| d(u^k, \hat{u}^k) \|^2_{G} \quad \text{Here } \kappa > 4. \\
(r, s), & \text{otherwise.}
\end{cases}
\]

Set \( k := k + 1 \).

Algorithm 1: General primal-dual relaxed-PPA method.

---

**Step 1. Initialization.** Let \( \gamma \in (0, 2) \) and pick \((x^0, \lambda^0) \in \mathbb{R}^n \times \Lambda\), set \( k = 0 \).

**Step 2. Predictor.** Let
\[
\hat{x}^k = P_{\Lambda} \left[ \lambda^k - \frac{1}{s} (A^T x^k - b) \right],
\]
and
\[
\hat{\lambda}^k = \text{Argmin} \left\{ \theta(x) + \frac{r}{2} \| x - \left[ x^k + \frac{1}{r} \Lambda^T \hat{x}^k \right] \|^2 \mid x \in \mathcal{X} \right\}.
\]

**Step 3.** If the stepsize \( r \) is chosen satisfying
\[
\varphi(u^k, \hat{u}^k) \geq \frac{1}{4} \| d(u^k, \hat{u}^k) \|^2_{G},
\]
then go to Step 4. Otherwise, increase \( r, s \) and go back to Step 2.

**Step 4. Corrector and updating**
\[
u^{k+1} = u^k - \alpha_k G^{-1} M(u^k - \hat{u}^k).
\]

**Step 5. Adjustment**
\[
(r, s) = \begin{cases} 
\left( \frac{r}{2}, \frac{s}{2} \right), & \text{if } \varphi(u^k, \hat{u}^k) \geq \kappa \cdot \| d(u^k, \hat{u}^k) \|^2_{G} \quad \text{Here } \kappa > 4. \\
(r, s), & \text{otherwise.}
\end{cases}
\]

Set \( k := k + 1 \).

Algorithm 2: General dual-primal relaxed-PPA method.

---

4. The General Self-Adaptive Relaxed PPA-Method

In this section, we weave together the ideas of the previous section to present general self-adaptive relaxed-PPA method (SRPPA) which is mostly inspired by LPPA [24]. At first sight, the predictor applied in SRPPA is much the same as LPPA, but the stepsize choice condition for convergence is quite different; moreover, we prove that it is weaker than LPPA. Self-adaptive strategies are elaborately designed to ensure the robustness of our algorithm. Two simple yet efficient constructions of new iterate are also presented which will provide some inspirations for designing various search directions.

4.1. General Relaxed-PPA Method. The general primal-dual relaxed-PPA method with implementable structure for (1) is summarized in Algorithm 1. Note that the order of \( x \) and \( \lambda \) can be changed to obtain a variant, which is summarized in Algorithm 2. Our relaxed-PPA is intended to blend the implementable properties of EGM (or PCM) with the fast convergence performance of PPA. Now, it is helpful to introduce additional notations that will be used in the rest of this paper. Let \( G \) be a positive symmetry definite matrix (we will specify it later),

\[
M = \begin{pmatrix} rI_n & A^T \\ 0 & sI_m \end{pmatrix}, \quad H = \begin{pmatrix} rI_n & 0 \\ 0 & sI_m \end{pmatrix},
\]

\[
d(u^k, \hat{u}^k) = G^{-1} M (u^k - \hat{u}^k),
\]

\[
\varphi(u^k, \hat{u}^k) = (u^k - \hat{u}^k)^T M (u^k - \hat{u}^k).
\]
The relaxed-PPA described here involves two steps. First, we solve the relaxed subproblem (\(*\)), (\(\ast\ast\)) to obtain predictor, which is nice and efficient for the nature of the problem under study. Note that the \(x\)-predictor step (\(*\)) involves minimizing \(\theta\) plus a convex quadratic function, and under Assumption 2, it can be efficiently solved or it admits a closed form solution. And then, \(\lambda\)-predictor step (\(\ast\ast\)) is just a projection onto \(\Lambda\) which is tractable and computationally efficient. It is clear that the prediction step employs a Gauss-Seidel manner to update information efficiently. The correction step (\(\$\)) only involves matrix-vector multiplication which is very simple and straightforward.

**Remark 3.** We first make some insight into the correction step in Algorithm 1. The obtained \(u^k\) plays no direct role as the new iterate. Instead, we need some kind of “corrector” defined in (\(\$\)). Although matrix \(G\) in (\(\$\)) is just a required positive symmetry definite, our goal here is to fully integrate the information of \(u^k\) and \(\tilde{u}^k\) to construct effective, simple search direction \(G^{-1}M(u^k - \tilde{u}^k)\) for the corrector. Based on this consideration, we elaborately provide two simple choices of \(G\).

**Case 1.** It is natural to set \(G = H\) to induce a simple update form. Then, it is easy to get that
\[
\begin{pmatrix}
    x^{k+1} \\
    \lambda^{k+1}
\end{pmatrix}
= \begin{pmatrix}
    x^k \\
    \lambda^k
\end{pmatrix} - \alpha_k \begin{pmatrix}
    x^k - \tilde{x}^k + \frac{1}{r} A^T (\lambda^k - \tilde{\lambda}^k) \\
    \lambda^k - \tilde{\lambda}^k
\end{pmatrix}. \tag{27}
\]

**Case 2.** Let \(G = MH^{-1}M^T\). This case is a little less intuitive, but it can lead to a simple update form as well as Case 1. The underlying derivation is a little more complicated. Applying \(G\) in (\(\$\)), we get
\[
\begin{align*}
    u^{k+1} &= u^k - \alpha_k M^{-T}HM^{-1}M(u^k - \tilde{u}^k) \\
    &= u^k - \alpha_k M^{-T}H(u^k - \tilde{u}^k). \tag{28}
\end{align*}
\]

Recalling \(M\) is a lower triangular matrix, by the fact that its inverse is also a lower triangular, we have
\[
G^{-1}M = M^T H = \begin{pmatrix}
    I_n & 0 \\
    -A & I_m
\end{pmatrix}. \tag{29}
\]

Plugging the previous relationship to (31), we have
\[
\begin{pmatrix}
    x^{k+1} \\
    \lambda^{k+1}
\end{pmatrix}
= \begin{pmatrix}
    x^k \\
    \lambda^k
\end{pmatrix} - \alpha_k \begin{pmatrix}
    x^k - \tilde{x}^k \\
    \lambda^k - \tilde{\lambda}^k - \frac{1}{s} A(x^k - \tilde{x}^k)
\end{pmatrix}. \tag{30}
\]

In fact, this is a scheme of Gaussian back substitution. Both cases only involve one matrix-vector multiplication which makes the update form simple. And the computational cost is usually inexpensive.

**Remark 4.** We now study the subproblem described in (\(*\)), (\(\ast\ast\)), and the stepsize choice condition (\(#\)). For easy analysis, we characterize (\(*\)), (\(\ast\ast\)) as the following VI formulation.

Find \((\tilde{x}^k, \tilde{\lambda}^k) \in \Omega\) such that
\[
\begin{pmatrix}
    x - \tilde{x}^k \\
    \lambda - \tilde{\lambda}^k
\end{pmatrix}^T \left\{ \begin{pmatrix}
    f(x^k) - A^T\tilde{\lambda}^k \\
    A\tilde{x}^k - b
\end{pmatrix} + \begin{pmatrix}
    rI_n & A^T \\
    0 & sI_m
\end{pmatrix} \begin{pmatrix}
    \tilde{x}^k - x^k \\
    \tilde{\lambda}^k - \lambda^k
\end{pmatrix} \right\} \geq 0, \quad \forall (x, \lambda) \in \Omega, \tag{31}
\]

and its compact form
\[
\begin{align*}
    u^k \in \Omega, \quad (u - u^k)^T \left\{ F(u^k) + M(u^k - u^k) \right\} &\geq 0, \tag{32} \\
    \forall u \in \Omega.
\end{align*}
\]

We observe that subproblem (32) is similar to (10) in PPA, except for the construction of asymmetry matrix \(M\). As mentioned before, (32) is the same as the prediction subproblem in [24]. Even though they are closely related, the stepsize choice here is quite different. We provide more specific and weaker condition for stepsize \(r, s\). It is clear that condition (\(\#\)) does not need prior knowledge of matrix \(A\). Furthermore, it only involves matrix-vector multiplication, and so, it is easy to verify, and it is amenable to large-scale \(A\). If \(r, s\) fail to meet this convergence condition (\(\#\)), one should appropriately increase \(r, s\). In the following subsection, we will elaborate on the self-adaptive strategies to increase the stepizes. At this point, condition (\(\#\)) may be seen somewhat unmotivated. Some insight into this will be provided later, as we proceed with the convergence analysis. The convergence condition in [24] has a quite different feature: \(r, s\) satisfy
\[
rs \geq \frac{1}{2} \| A^T A \| . \tag{33}
\]

It is stronger than condition (\(\#\)). The following lemma is devoted to the proof of this result.

**Lemma 5.** Let \(\{u^k\}\) be the sequence generated by Algorithm 1, \(H, d(u^k, \tilde{u}^k)\), and \(\varphi(u^k, \tilde{u}^k)\) defined in (24), (25), and (26), respectively. Suppose that condition (33) is satisfied. Then, condition (\(\#\)) holds immediately.

**Proof.** Note that
\[
\varphi(u^k, \tilde{u}^k) = r\| x^k - \tilde{x}^k \|^2 + s\| \lambda^k - \tilde{\lambda}^k \|^2 + (\lambda^k - \tilde{\lambda}^k)^T A (x^k - \tilde{x}^k) . \tag{34}
\]

Recall that matrix \(G\) described in Algorithm 1 can be designed in two different cases.

**Case 1.** If \(G = H\), we immediately have
\[
\| d(u^k, \tilde{u}^k) \|^2_G = \| u^k - \tilde{u}^k \|^2_H + \frac{1}{r} \| A^T(\lambda^k - \tilde{\lambda}^k) \|^2 + 2 \| \lambda^k - \tilde{\lambda}^k \|^2 A (x^k - \tilde{x}^k) . \tag{35}
\]
According to Cauchy-Schwarz inequality, we get
\[
\varphi \left( u^k, \bar{u}^k \right) - \frac{1}{4} \| d \left( u^k, \bar{u}^k \right) \|_G^2 = \frac{3}{4} \left( \lambda^k - \bar{\lambda}^k \right)^T A \left( \lambda^k - \bar{\lambda}^k \right)
\]
\[
= \frac{3}{4} \| u^k - \bar{u}^k \|_H^2 - \frac{1}{2} \| A^T \left( \lambda^k - \bar{\lambda}^k \right) \|_2^2
\]
\[
+ \frac{1}{2} \left( \lambda^k - \bar{\lambda}^k \right)^T A \left( x^k - \bar{x}^k \right)
\]
\[
\quad \geq \frac{3}{4} \| u^k - \bar{u}^k \|_H^2 - \frac{1}{2} \| A^T \left( \lambda^k - \bar{\lambda}^k \right) \|_2^2
\]
\[
- \frac{1}{4} \left( 2r \| x^k - \bar{x}^k \|_2^2 + \frac{1}{2r} \| A^T \left( \lambda^k - \bar{\lambda}^k \right) \|_2^2 \right)
\]
\[
= \frac{r}{4} \| x^k - \bar{x}^k \|_2^2 + \frac{3s}{4} \| \lambda^k - \bar{\lambda}^k \|_2^2
\]
\[
\quad - \frac{3}{8r} \| A^T \left( \lambda^k - \bar{\lambda}^k \right) \|_2^2 \geq \frac{r}{4} \| x^k - \bar{x}^k \|_2^2.
\]

The last inequality follows directly from condition (33).

Case 2. If $G = MH^{-1}M^T$, by the definition of $d(u^k, \bar{u}^k)$, we obtain
\[
\| d \left( u^k, \bar{u}^k \right) \|_G^2 = \left( u^k - \bar{u}^k \right)^T M^T G^{-1} M \left( u^k - \bar{u}^k \right)
\]
\[
= \| u^k - \bar{u}^k \|_H^2.
\]

Then, we get
\[
\varphi \left( u^k, \bar{u}^k \right) - \frac{1}{4} \| d \left( u^k, \bar{u}^k \right) \|_G^2
\]
\[
= \frac{3}{4} \| u^k - \bar{u}^k \|_H^2 + \left( \lambda^k - \bar{\lambda}^k \right)^T A \left( x^k - \bar{x}^k \right)
\]
\[
\geq \frac{3}{4} \| u^k - \bar{u}^k \|_H^2 - \frac{1}{2} \| A^T \left( \lambda^k - \bar{\lambda}^k \right) \|_2^2
\]
\[
- \frac{1}{4} \left( 2r \| x^k - \bar{x}^k \|_2^2 + \frac{1}{2r} \| A^T \left( \lambda^k - \bar{\lambda}^k \right) \|_2^2 \right)
\]
\[
= \frac{r}{12} \| x^k - \bar{x}^k \|_2^2 + \frac{3s}{4} \| \lambda^k - \bar{\lambda}^k \|_2^2 - \frac{3}{8r} \| A^T \left( \lambda^k - \bar{\lambda}^k \right) \|_2^2
\]
\[
\quad \geq \frac{r}{12} \| x^k - \bar{x}^k \|_2^2.
\]

The first inequality follows from the Cauchy-Schwarz inequality, and the last one follows directly from condition (33).

Note that, in both cases, we have that condition (#) holds if $rs \geq (1/2) \| A^T A \|$.

Condition (33) is not only stronger than Condition (#), but it also requires that matrix $M$ is positive semidefinite, while condition (#) does not. Furthermore, condition (33) may require the explicit expression of $A$ or knowledge of $\| A^T A \|$. Despite these drawbacks, condition (33) is appealing to the problems in which $\| A^T A \|$ is known beforehand or easy to compute/obtain. For instance, $A$ is small scale, an identity matrix or a projection operator, and so forth. It is clear that both condition (#) and (33) are more flexible than the one in PPA-CM [23]. The most aggressive condition (#) may lead to further improvement in stepsize choice. Moreover, it is worthwhile to notice that condition (#) is elegantly designed and provides $\varphi(u^k, \bar{u}^k)$ with favourable property. In fact, for general matrix $G$, condition (#) also can guarantee convergence.

**Remark 6.** The update stepsize $\alpha_k$ plays an important role here. In fact, it can be regarded as an optimal stepsize which will be illustrated in the following section.

**Remark 7.** We should restrict the adjustment in Step 5 of Algorithm 1 within a limited number to avoid divergence.

In Algorithm 1, we carry out the $x$-predictor before performing $\lambda$-predictor. The roles of $x$ and $\lambda$ are symmetric; hence, sweeping the order will not break the Gauss-Seidel structure. We switch $x$ and $\lambda$ and obtain a variant of relaxed-PPA with the order of the $x$-predictor step and $\lambda$-predictor step reversed. This variant is illustrated in Algorithm 2. However, there is no a priori information to know which algorithm is superior. Here, we let
\[
M = \begin{pmatrix} rI_n & 0 \\ -A & sl_m \end{pmatrix}.
\]

4.2. Adaptive Enhancements. Both PPA-CM and LPPA employ fixed stepsizes $r, s$. Experiments reveal that they will suffer slow convergence when stepsizes $r, s$ are chosen inappropriately. A natural question is, how to choose the proper initial stepsizes $r, s$? Here, we propose self-adaptive strategies with the goal of improving the convergence in practice, as well as making performance less dependent on the initial choice of stepsizes. Our strategies dynamically incorporate the information of the current iteration to perform more informative choice of stepsizes for the next iteration [31]. When doing so, the algorithm will be adaptive and free from the initial choice.

Denote
\[
\begin{pmatrix} d^k_x \\ d^k_\lambda \end{pmatrix} = \begin{pmatrix} \left( x^k - \bar{x}^k \right) + \frac{1}{r} A^T \left( \lambda^k - \bar{\lambda}^k \right) \\ \lambda - \bar{\lambda} \end{pmatrix},
\]
and then, (31) can be rewritten as
\[
\begin{pmatrix} x - \bar{x} \end{pmatrix}^T \left( \begin{pmatrix} A^T \bar{A} \end{pmatrix} - \begin{pmatrix} rI_n & 0 \\ 0 & sl_m \end{pmatrix} \begin{pmatrix} d^k_x \\ d^k_\lambda \end{pmatrix} \right) \geq 0,
\]
\[
\forall \begin{pmatrix} x \\ \lambda \end{pmatrix} \in \Omega.
\]

Under $H$-norm, the quantity $d^k_x$ can be viewed as a residual for the dual feasibility condition, and $d^k_\lambda$ can be viewed as a primal residual. These two residuals converge to zero as relaxed-PPA proceeds. Note that
\[
\| d^k_x \|_r^2 = r \| x^k - \bar{x}^k \|_2^2 + 2 \left( x^k - \bar{x}^k \right)^T A^T \left( \lambda^k - \bar{\lambda}^k \right)
\]
\[
\quad + \frac{1}{r} \| A^T \left( \lambda^k - \bar{\lambda}^k \right) \|_2^2,
\]
\[
\| d^k_\lambda \|_s^2 = s \| \lambda^k - \bar{\lambda}^k \|_2^2.
\]
And this implies that small values of \( s \) tend to reduce the primal residual but have potential to enlarge violations of dual feasibility and tend to produce larger dual residual. This observation motivates us to balance primal and dual residuals. When condition (\#) fails, we increase stepsizes \( r, s \) properly according to the adaptation shown in Algorithm 3.

Here, \( \tau_1 > 1, \tau_2 > 1 \). This adaptation strategy increases \( s \) when the dual residual \( \|d^k_s\|^2 \) appears large compared to the primal residual \( \|d^k_s\|^2 \), and increases \( r \) when the dual residual \( \|d^k_s\|^2 \) seems too small relative to the primal residual \( \|d^k_s\|^2 \).

As mentioned, condition (33) is stronger than condition (\#). If one chooses condition (33), our RPPA also converges. It must have predetermined stepsizes satisfying \( rs = \mu \|AA^T\| \) (here, \( \mu \geq 0.5 \)). However, there is no priority knowledge of the choice of individual \( r \) or \( s \). Here, we can also adjust \( r, s \) automatically when choosing condition (33). Intuitively, we consider expansion of the entire residual under \( H \)-norm:

\[
\|d^k_s\|^2 + \|d^k_s\|^2 \\
= r\|\lambda^k - \lambda^k\|^2 + s\|\lambda^k - \lambda^k\|^2 \\
+ \frac{1}{r}\|AA^T(\lambda^k - \lambda^k)\|^2 + 2(\lambda^k - \lambda^k)^T A^T(\lambda^k - \lambda^k) \quad (43)
\]

there are three terms involving \( r \) or \( s \), and we intend to balance these terms. For fixed \( \mu \), take \( s = (\mu/r)\|AA^T\| \); then

\[
s\|\lambda^k - \lambda^k\|^2 = \frac{\mu}{r}\|AA^T\|\|\lambda^k - \lambda^k\|^2. \quad (44)
\]

Applying (44) into (43), clearly we have

\[
\|d^k_s\|^2 + \|d^k_s\|^2 \\
= r\|\lambda^k - \lambda^k\|^2 + \frac{1}{r}\bigg(\mu\|AA^T\|\|\lambda^k - \lambda^k\|^2 + \|A^T(\lambda^k - \lambda^k)\|^2\bigg) \\
+ 2(\lambda^k - \lambda^k)^T A^T(\lambda^k - \lambda^k) \quad (45)
\]

Now, we consider adjusting stepsize to balance \( r\|\lambda^k - \lambda^k\|^2 \) and \( (1/r)(\mu\|AA^T\|\|\lambda^k - \lambda^k\|^2 + \|A^T(\lambda^k - \lambda^k)\|^2) \) and obtain another adaptation strategy (see Algorithm 4).

It is worth noting that too many adjustments of stepsizes by Algorithm 4 might cause the algorithm to diverge in practice, and we therefore restrict these adaptations within a limited number of iterations. If one chooses Algorithm 4, there is no need to carry out Step 5 in Algorithm 1 (or Algorithm 2). These techniques embedded into relaxed-PPA automatically choose a “better” stepsize for the next iteration.

5. Convergence Analysis

In this section, we analyze convergence of our primal-dual relaxed-PPA. The convergence analysis of dual-primal scheme can follow a similar procedure.

Let \( u^* = (x^*, \lambda^*) \) be any solution point, setting \( u = u^* \) in (32) yields

\[
(\tilde{u}^k - u^*)^T M (u^k - \tilde{u}^k) \geq (\tilde{u}^k - u^*)^T F (\tilde{u}^k) \quad (46)
\]
Since \( \bar{u}^k \in \Omega \), we have \((\bar{u}^k - u^*)^T F(u^*) \geq 0 \). Consequently, by using the monotonicity of \( F \), the right hand side of (46) is nonnegative, and thus
\[
(\bar{u}^k - u^*)^T M (u^k - \bar{u}^k) \geq 0.
\]
(47)
Now, we are writing the update as
\[
u (\alpha) = u^k - \alpha d (u^k, \bar{u}^k)
\]
and
\[
\theta (\alpha) := \|u^k - u^*\|_G^2 - \|u(\alpha) - u^*\|_G^2.
\]
(49)
\[
q(\alpha) = 2\alpha(\bar{u}^k - u^k)^T G \tilde{d} \left(u^k, \bar{u}^k\right) - \alpha^2 \|d (u^k, \bar{u}^k)\|_G^2.
\]
Here, \( \theta (\alpha) \) can be viewed as a progress function. The following lemma shows that \( q(\alpha) \) is a lower bound of \( \theta (\alpha) \).

Lemma 8. Let \( \theta (\alpha) \) and \( q(\alpha) \) be defined in (49); then one has
\[
\theta (\alpha) \geq q(\alpha).
\]
(50)
Proof. Let \( u^* \) be any solution, from the definition of \( u(\alpha) \), we have
\[
\theta (\alpha) = \|u^k - u^*\|_G^2 - \|u(\alpha) - u^*\|_G^2
\]
(51)
\[
= 2\alpha(\bar{u}^k - u^k)^T G \tilde{d} \left(u^k, \bar{u}^k\right) - \alpha^2 \|d (u^k, \bar{u}^k)\|_G^2.
\]
(52)
Applying (47) to the first term of (51) gives
\[
\langle u^k - u^* \rangle^T G \tilde{d} \left(u^k, \bar{u}^k\right) = \langle u^k - \bar{u}^k \rangle^T G \tilde{d} \left(u^k, \bar{u}^k\right)
\]
(53)
\[
+ \langle \bar{u}^k - u^k \rangle^T G \tilde{d} \left(u^k, \bar{u}^k\right).
\]
(54)
Substituting (52) into (51), we immediately obtain the assertion.

We note that \( q(\alpha) \) is a quadratic function of \( \alpha \) and it is natural to maximize \( q(\alpha) \) to obtain an “optimal” \( \alpha \):
\[
\alpha^*_k = \left(\frac{(\bar{u}^k - u^k)^T G \tilde{d} \left(u^k, \bar{u}^k\right)}{\|d (u^k, \bar{u}^k)\|_G^2}\right).
\]
(55)
We now show that the “optimal” \( \alpha^*_k \) is bounded above from zero in the following Lemma.

Lemma 9. Let sequence \( \{u^k\} \) be produced by Algorithm 1, \( \alpha^*_k \) defined in (53); then one has
\[
\alpha^*_k \geq \frac{1}{4} > 0.
\]
(56)
Proof. Using the definition of \( \alpha^*_k \) in (53), we have, for all \( k \),
\[
\alpha^*_k \geq \left(\frac{\varphi(u^k, \bar{u}^k)}{\|d (u^k, \bar{u}^k)\|_G}\right) \geq \frac{1}{4}.
\]
(57)
The inequality follows from condition (#).
The problem constrained representations in overcomplete dictionaries by equality-Basis pursuit (BP) finds signal

6.1. Basis Pursuit Problem.

3.2GHz and 3.5GB RAM. desktop computer with Intel (R) Core (TM) i5 CPU with all the numerical experiments were performed on a Lenovo of iterations and computational times. Our experiments focus on efficiency and speed of convergence and evaluate the methods in terms of their number

lems. Our experiments test here is similar to the one employed in illustrate the nice performance of our RPPA. The synthetic section use synthetic data which were mainly designed to

over-complete representations. Our experiments in this subsection use synthetic data which were mainly designed to illustrate the nice performance of our RPPA. The synthetic problem that we test here is similar to the one employed in [32], we generate the data as follows: matrix

problem (66). Hence, in our synthetic problem, $x_{\text{original}}$ is exactly the solution.

In our first experiment, we compared general RPPA using two different G’s mentioned in Section 4.1. For BP problem, we use condition ($\theta$) and Algorithm 3. Since A constructed here is a general random matrix, and when A is large scale, $\|A^T A\|$ might be obtained costly. A simple stopping criterion

was used in this experiment, and the stopping tolerance Tol was set to $10^{-10}$. In all the tests, initial step sizes were set as $s = 10$, $r = 1$, the primal variable $x^0$ was initialized as zeros(n, 1), and the dual $\lambda^0$ was ones(m, 1) in Matlab. Table I summarizes the performance of general SRPPA. Here, SDPRPPAG-I(SDPRPPAG-I) denotes self-adaptive primal-dual RPPA with Algorithm 3 (Algorithm 4), $G = H$, if $i = 1$, and $G = MH^{-1}MT$, if $i = 2$. DPRPPA (DPRPPA) denotes dual-primal RPPA version.

Basically, SRPPAs converge very quickly and achieved tight error $10^{-10}$ in a few hundred iterations. For this experiment, one can see that SDPRPPAG-I is fastest in all cases. Both SDPRPPAG-I and SDPRPPAG-I are Gaussian type methods, with $G = H$, and they exhibit very similar performance. SDPRPPAG2-I and SDPRPPAG2-I with $G = MH^{-1}MT$ are Gaussian back substitute form methods and perform a little slower than Gaussian type methods. We also plot a figure to graphically illustrate the performance of four SRPPAs. Figure 1 shows the results from the test with $n = 1000$ and $n = 6000$, depicting error versus CPU time. Quality-wise, SDPRPPAG-I was on par with SDPRPPAG-I.

In the second experiment, we compare the performance of SDPRPPAG-I with TFOCS (source code can be found at http://cvxr.com/tfocs/) [32], ADMM (source code can be found at http://www.stanford.edu/~boyd/papers/admm/) [33], and PPA-CM. To make the comparison independent of the stopping criterion for each algorithm, we first run TFOCS to get its solution $x_{\text{TFOCS}}$ and set a benchmark error

and then run other algorithms until they obtain smaller errors than this benchmark. TFOCS was stopped upon

$\|x_{\text{TFOCS}}^k - x_{\text{original}}\|_2 \leq \text{Tol}$ (68)

$\max \{1, \|x_{\text{TFOCS}}^k\|\} \leq \text{Tol}$ (69)
Since we found that $\text{Tol} = 10^{-12}$ is small enough to guarantee very high accuracy, we set $\text{Tol} = 10^{-12}$ in TFOCS. The parameters of TFOCS and ADMM were taken with their defaults. To guarantee the convergence, fixed step sizes $r, s$ were set to $s = 100, r = 1.01 \times \|A A^T\| / s$ for PPA-CM. In SPDRPPAG1-I, we also choose the same convergence condition (#) and initial step size $s = 10, r = 1$ as the previous experiment. We varied the size of $A$ from $n = 512 \ (m = n/2)$ to $n = 8500$. The results of this experiment are summarized in Table 2. There, we report the run time in seconds, the number of iterations, and the error of the recovery solution. In Table 2, “—” means “out of memory.”

We observe from Table 2 that four algorithms reach high accuracy around $10^{-9}$. SPDRPPAG1-I is about two times faster than the first-order method implemented in the TFOCS package, and moreover, it usually outperforms TFOCS in terms of iterations. For medium size problems, SPDRPPAG1-I is clearly faster than ADMM. Even for small size problems, SPDRPPAG1-I shows its superior performance. The main reason lies in that ADMM computed $(I + AA^T)^{-1}$ to solve its subproblem exactly which would take expensive computational cost. Not surprisingly, the general SPDRPPAG1-I performs better than the primary PPA-CM. Here, the total iterations of SPDRPPAG1-I are less than 50%
of PPA-CM. As we have mentioned, “optimal” update stepsize \( \alpha_k \) and more flexible condition for convergence may provide SPDRPPAG1-I improved performance. SPDRPPAG1-I is faster than PPA-CM in terms of CPU times. However, the superiority of CPU time is not so significant as iteration number. For the cases \( n = 4300 \), it is just about 62\% of PPA-CM. This is not particularly surprising; compared to PPA-CM, SPDRPPAG1-I has to take extra computation for convergence condition and “optimal” \( \alpha_k \) in each iteration.

6.2. Nearest Correlation Matrix Problem. The nearest correlation matrix problem is solving the problem

\[
\min \left\{ \frac{1}{2} \| X - C \|^2_F \mid \text{diag}(X) = e, X \in S^n_+ \right\}, \tag{70}
\]

where \( e \in \mathbb{R}^n \) is the vector whose entries are all 1s, \( S^n_+ \) denotes the cone of positive definite symmetric matrices, \( \text{diag}(X) \) is the vector of diagonal elements of \( X \), and \( \| \cdot \|_F \) denotes the matrix Frobenius norm \( \| X \|_F = \text{trace}(X^T X)^{1/2} \).

Here, we apply PPA-CM, LPPA, and SDPRPPAG1-II for solving (70). The standard Matlab Mex interface mexsvd is used to conduct the eigenvalue decomposition. We constructed test data sets and stopping criterion like those of [24]. As mentioned in the prequel, we expect our SRPPA to produce robust performance. To assess the effectiveness of the adaptive strategies proposed in Section 6, we now move on to the description of experiments that focus on the consequences of the initial stepsizes. For investigating, we used dimensions \( n \in \{500, 1000\} \) and varied \( s \) from 0.05 to 100, and initial points were set to 0 in all cases. Note that \( A = I \); we fixed \( r = 1.01/s \) for PPA-CM, \( r = 0.65/s \) for LPPA and chose \( r = 0.65/s \) as initial start for SDPRPPAG1-II. Since the experiments with other values of \( n \) give qualitatively similar results, we therefore do not plot those results to avoid clutter in the figures. The respective numerical results are plotted in Figure 2.

It is clear that, for PPA-CM and LPPA, the convergence performance was a result of the stepsize selection. They are both fairly sensitive to initial stepsize \( s \) (or \( r \)). The results confirm that, with inappropriate stepsizes, both PPA-CM and LPPA become significantly slow. SDPRPPAG1-II yields significantly robust performance with adaptive strategy. And it is independent of the initial stepsizes and illustrates its superior performance. Furthermore, SDPRPPAG1-II yields competitive results even when PPA-CM and LPPA chose the “good” initial stepsize. This underlies the importance of adaptive strategy in producing good performance. Of course, care should be taken. For instance, the cost of computing optimal stepsize \( \alpha_k \) here is negligible, compared to the computation of SVD; when they are more costly, general LPPA will be expected to perform slower than PPA-CM.

7. Conclusions

In this paper, we proposed an efficient general self-adaptive relaxed-PPA method for linearly constrained convex programming and provided theoretical convergence analysis for...
this method. The stepsizes choice condition is flexible and simple. Self-adaptive strategies are provided to make our method more efficient and robust. Experiments of the method in comparison to other state-of-art methods are provided to confirm the efficiency of the proposed method. Our numerical results suggest that SRPPA is effective and simple to implement. There are a few directions for further research, but we list here only two. The first is the question of whether we may modify the algorithm to work with more general constrained convex problems. Second, we aim to provide various relaxations of the subproblem for the practical purpose.

Acknowledgments

The basic motivation of this paper is to extend, generalize, and improve several fundamental results on the existence (and uniqueness) of coincidence points and fixed points for well-known maps in the literature such as Kannan type, Chatterjea type, Mizoguchi-Takahashi type, Berinde-Berinde type, Du type, and other types from the class of self-maps to the class of non-self-maps in the framework of the metric fixed point theory. We establish some fixed/coincidence point theorems for multivalued non-self-maps in the context of complete metric spaces.

1. Introduction

During the last few decades, the celebrated Banach contraction principle, also known as the Banach fixed point theorem [1], has become one of the core topics of applied mathematical analysis. As a consequence, a number of generalizations, extensions, and improvement of the praiseworthy Banach contraction principle in various direction have been explored and reported by various authors; see, for example, [2–30] and the references therein. In parallel with the Banach contraction principle, Kannan [5] and Chatterjea [6] created, respectively, different type, fixed point theorems as follows.

Theorem 1 (Kannan). Let \((X,d)\) be a complete metric space, \(T : X \to X\) is a single-valued map, and \(\gamma \in [0, 1/2)\). Assume that
\[
d(Tx,Ty) \leq \gamma [d(x,Tx) + d(y,Ty)] \quad \forall x, y \in X. \tag{1}
\]
Then \(T\) has a unique fixed point in \(X\).

Theorem 2 (Chatterjea). Let \((X,d)\) be a complete metric space, \(T : X \to X\) is a single-valued map, and \(\gamma \in [0, 1/2)\). Assume that
\[
d(Tx,Ty) \leq \gamma [d(x,Ty) + d(y,Tx)] \quad \forall x, y \in X. \tag{2}
\]
Then \(T\) has a unique fixed point in \(X\).

The characterization of the renowned Banach fixed point theorem in the setting of multivalued maps is one of the most outstanding ideas of research in fixed point theory. The remarkable examples in this trend were given by Nadler [2], Mizoguchi and Takahashi [3], and M. Berinde and V. Berinde [4]. On the other hand, investigation of the existence of a fixed point of non-self-maps under certain condition is an interesting research subject of metric fixed point theory, see, for example, [19–27], and references therein.

The following attractive result was reported by M. Berinde and V. Berinde [4] in 2007.

Theorem 3 (M. Berinde and V. Berinde). Let \((X,d)\) be a complete metric space, \(T : X \to \mathcal{CB}(X)\) a multivalued map, \(\varphi : [0, \infty) \to [0, 1)\) an \(\mathcal{M}\mathcal{F}\)-function (i.e., \(\lim \sup_{s \to t} \varphi(s) < 1\) for all \(t \in [0, \infty)\)), and \(L \geq 0\). Assume that
\[
\mathcal{H}(Tx,Ty) \leq \varphi(d(x,y))d(x,y) + Ld(y,Tx) \quad \forall x, y \in X. \tag{3}
\]
Then \(T\) has a fixed point in \(X\).

If we take \(L = 0\) in Theorem 3, then we conclude the remarkable result of Mizoguchi and Takahashi [3] which is a partial answer of problem 9 in [8].
Theorem 4 (Mizoguchi and Takahashi). Let \((X,d)\) be a complete metric space, \(T : X \rightarrow CB(X)\) a multivalued map, and \(\varphi : [0, \infty) \rightarrow [0, 1)\) an \(M\)-function. Assume that
\[
H(Tx, Ty) \leq \varphi(d(x, y))d(x, y) \quad \forall x, y \in X. \tag{4}
\]
Then \(T\) has a fixed point in \(X\).

Recently, Du [12] established the following theorem which is an extension of Theorem 3 and hence Theorem 4.

Theorem 5 (Du). Let \((X,d)\) be a complete metric space, \(T : X \rightarrow CB(X)\) a multivalued map, \(\varphi : [0, \infty) \rightarrow [0, 1)\) an \(M\)-function and \(h : X \rightarrow [0, 0)\) a function. Assume that
\[
H(Tx, Ty) \leq \varphi(d(x, y))d(x, y) + h(y)d(y, Tx) \quad \forall x, y \in X. \tag{5}
\]
Then \(T\) has a fixed point in \(X\).

The basic objective of this paper is to investigate the existence of coincidence and fixed points of multivalued non-self-maps under the certain conditions in the setting of metric spaces. The presented results generalize, improve, and extend several crucial and notable results that examine the existence of the coincidence/fixed point of well-known maps such as Kannan type, Chatterjea type, Mizoguchi-Takahashi type, Berinde-Berinde type, Du type, and other types in the context of complete metric spaces.

2. Preliminaries

Let \((X,d)\) be a metric space. For each \(x \in X\) and \(A \subseteq X\), let \(d(x, A) = \inf_{y \in A} d(x, y)\). Denote by \(N(X)\) the class of all nonempty subsets of \(X\) and \(CB(X)\) the family of all nonempty closed and bounded subsets of \(X\). A function \(H : CB(X) \times CB(X) \rightarrow [0, \infty)\) is said to be the Hausdorff metric on \(CB(X)\) induced by the metric \(d\) on \(X\). It is also known that \((CB(X), H)\) is a complete metric space whenever \((X,d)\) is a complete metric space.

Let \(K\) be a nonempty subset of \(X\), \(g : K \rightarrow X\) a single-valued map, and \(T : K \rightarrow N(X)\) a multivalued map. A point \(x \in X\) is a coincidence point of \(g\) and \(T\) if \(gx \in Tx\). If \(g = \text{id}\) is the identity map, then \(x = gx \in Tx\) and call \(x\) a fixed point of \(T\). The set of fixed points of \(g\) and the set of coincidence point of \(g\) and \(T\) are denoted by \(\mathcal{F}(T)\) and \(\mathcal{CP}_K(g, T)\), respectively. In particular, if \(K \equiv X\), we use \(\mathcal{F}(T)\) and \(\mathcal{CP}(g, T)\) instead of \(\mathcal{F}(T)\) and \(\mathcal{CP}_K(g, T)\), respectively. Throughout this paper, we denote by \(\mathbb{N}\) and \(\mathbb{R}\), the set of positive integers and real numbers, respectively.

Let \(f\) be a real-valued function defined on \(\mathbb{R}\). For \(c \in \mathbb{R}\), we recall that
\[
\lim \sup_{x \to c} f(x) = \inf_{c \leq x \leq c + \varepsilon} \sup_{x \in B} f(x). \tag{7}
\]

Definition 6 (see [9-18]). A function \(\varphi : [0, \infty) \rightarrow [0, 1)\) is said to be an \(M\)-function (or \(R\)-function) if \(\lim_{s \to 0^+} \varphi(s) < 1\) for all \(t \in [0, \infty)\).

It is evident that if \(\varphi : [0, \infty) \rightarrow [0, 1)\) is a nondecreasing function or a nonincreasing function, then \(\varphi\) is an \(M\)-function. So the set of \(M\)-functions is a rich class. An example which is not an \(M\)-function is given as follows.

Let \(\varphi : [0, \infty) \rightarrow [0, 1)\) be defined by
\[
\varphi(t) = \begin{cases} \sin \frac{t}{t}, & \text{if } t \in \left[0, \frac{\pi}{2}\right] \\ 0, & \text{otherwise} \end{cases} \tag{8}
\]

We note that \(\varphi\) is not an \(M\)-function, since \(\lim_{s \to 0^+} \varphi(s) = 1\).

In what follows that, we recall some characterizations of \(M\)-functions proved first by Du [12].

Theorem 7 (see [12]). Let \(\varphi : [0, \infty) \rightarrow [0, 1)\) be a function.

Then the following statements are equivalent.

(a) \(\varphi\) is an \(M\)-function.

(b) For each \(t \in [0, \infty)\), there exist \(r^{(1)}_t \in [0, 1)\) and \(e^{(1)}_t > 0\) such that \(\varphi(s) \leq r^{(1)}_t\) for all \(s \in [t, t + e^{(1)}_t]\).

(c) For each \(t \in [0, \infty)\), there exist \(r^{(2)}_t \in [0, 1)\) and \(e^{(2)}_t > 0\) such that \(\varphi(s) \leq r^{(2)}_t\) for all \(s \in [t, t + e^{(2)}_t]\).

(d) For each \(t \in [0, \infty)\), there exist \(r^{(3)}_t \in [0, 1)\) and \(e^{(3)}_t > 0\) such that \(\varphi(s) \leq r^{(3)}_t\) for all \(s \in [t, t + e^{(3)}_t]\).

(e) For each \(t \in [0, \infty)\), there exist \(r^{(4)}_t \in [0, 1)\) and \(e^{(4)}_t > 0\) such that \(\varphi(s) \leq r^{(4)}_t\) for all \(s \in [t, t + e^{(4)}_t]\).

(f) For any nonincreasing sequence \(\{x_n\}_{n \in \mathbb{N}}\) in \([0, \infty)\), \(x_n \leq \varphi(x_n)\) for all \(n \in \mathbb{N}\).

(g) \(\varphi\) is a function of contractive factor; that is, for any strictly decreasing sequence \(\{x_n\}_{n \in \mathbb{N}}\) in \([0, \infty)\), \(x_n \leq \varphi(x_n)\) for all \(n \in \mathbb{N}\).

3. Existence Theorems of Coincidence Points and Fixed Points for Multivalued Non-Self-Maps of Kannan Type and Chatterjea Type

In this section, we prove the existence of coincidence points and fixed points of multivalued non-self-maps of Kannan type and Chatterjea type. For this purpose, we first established a new intersection theorem of \(\mathcal{CP}_K(g, T)\) and \(\mathcal{F}_K(T)\) for multivalued non-self-maps in complete metric spaces.

Theorem 8. Let \((X,d)\) be a complete metric space, \(K\) a nonempty closed subset of \(X\), \(T : K \rightarrow CB(X)\) a multivalued map and \(g : K \rightarrow X\) a continuous self-map. Suppose that

(D1) \(Tx \cap K \neq \emptyset\) for all \(x \in K\),

(D2) \(Tx \cap K\) is \(g\)-invariant (i.e., \(g(Tx \cap K) \subseteq Tx \cap K\)) for each \(x \in K\),
Proof. Since $K$ a nonempty closed subset of $X$ and $X$ is complete, $(K,d)$ is also a complete metric space. Let $x \in K$. Put $k = \gamma/(1-\gamma)$ and $\lambda = (1 + k)/2$. So $0 \leq k < \lambda < 1$. Let $y \in T x \cap K$ be arbitrary. Then $d(y,T x \cap K) = 0$. By (D2), we have $d(gy,T x \cap K) = 0$. Hence (9) implies

$$H(T x, Ty \cap K) \leq \gamma \left[ d(x, T x \cap K) + d(y, T x \cap K) \right]$$

(10)

\forall y \in T x \cap K.

Inequality (10) shows that

$$d(y, Ty \cap K) \leq k d(x, T x \cap K) < \lambda d(x, y)$$

(11)

\forall y \in T x \cap K.$$

Let $x \in K$ be given. Take $x_1 = x$. By (D1), $T x_1 \cap K \neq \emptyset$. Choose $x_2 \in T x_1 \cap K$. If $x_2 = x_1$, then $x_1 \in \mathcal{F}_K(T)$ and hence $g x_1 \in T x_1$ from (D2). Hence $x_1 \in \mathcal{COP}_K(g,T) \cap \mathcal{F}_K(T)$ and the proof is finished. Otherwise, if $x_2 \neq x_1$, then $d(x_1, x_2) > 0$. By (11), we have

$$d(x_2, T x_2 \cap K) < \lambda d(x_1, x_2),$$

(12)

which implies that there exists $x_3 \in T x_2 \cap K$ such that

$$d(x_2, x_3) < \lambda d(x_1, x_2).$$

(13)

Next, by (11) again, there exists $x_4 \in T x_3 \cap K$ such that

$$d(x_3, x_4) < \lambda d(x_2, x_3).$$

(14)

By induction, we can obtain a sequence $\{x_n\}$ in $K$ satisfying

$$x_{n+1} \in T x_n \cap K,$$

(15)

$$d(x_{n+1}, x_{n+2}) < \lambda d(x_n, x_{n+1}).$$

(16)

By (16), we have

$$d(x_{n+1}, x_{n+2}) < \lambda d(x_n, x_{n+1})$$

$$< \lambda^2 d(x_{n-1}, x_n)$$

$$< \cdots$$

$$< \lambda^n d(x_1, x_2), \quad \text{for } n \in \mathbb{N}.$$

Let $\rho_n = (\lambda^{n-1}/(1-\lambda))d(x_1, x_2), n \in \mathbb{N}$. For $m, n \in \mathbb{N}$ with $m > n$, we have

$$d(x_n, x_m) \leq \sum_{j=n}^{m-1} d(x_j, x_{j+1}) < \rho_n.$$ 

(18)

Since $0 < \lambda < 1$, $\lim_{n \to \infty} \rho_n = 0$ and hence $\lim_{n \to \infty} \sup\{d(x_n, x_m) : m > n\} = 0$. This proves that $\{x_n\}$ is a Cauchy sequence in $K$. By the completeness of $K$, there exists $v \in K$ such that $x_n \to v$ as $n \to \infty$. By (15) and (D2), we have

$$g x_{n+1} \in T v \cap K$$

(19)

for each $n \in \mathbb{N}$.

Since $g$ is continuous and $\lim_{n \to \infty} x_n = v$, we have

$$\lim_{n \to \infty} g x_n = g v.$$ 

(20)

Since the function $x \mapsto d(x, T v)$ is continuous, by (9), (15), (19), and (20), we get

$$d(v, T v \cap K) = \lim_{n \to \infty} d(x_{n+1}, T v \cap K)$$

$$\leq \lim_{n \to \infty} H(T x, T v \cap K)$$

$$\leq \lim_{n \to \infty} \gamma \left[ d(x_n, T x \cap K) + d(v, T x \cap K) \right]$$

$$+ d(v, T v \cap K)$$

$$+ h(v) d(g v, T x \cap K)$$

$$\leq \gamma d(v, T x \cap K)$$

$$+ d(v, T x \cap K)$$

$$+ h(v) d(g v, T x \cap K),$$

(21)

which implies $d(v, T v \cap K) = 0$. By the closedness of $T v$, we have $v \in T v \cap K$. From (D2), $g v \in T v \cap K \subseteq T v$. Hence we verify $v \in \mathcal{COP}_K(g,T) \cap \mathcal{F}_K(T)$. The proof is complete. \qed

Theorem 9. In Theorem 8, if condition (D3) is replaced with one of the following conditions:

(K1) there exist a function $h : K \to [0, \infty)$ and $\gamma \in [0, 1/2)$ such that

$$H(T x, T y \cap K) \leq \gamma \left[ d(x, T x \cap K) + d(y, T y \cap K) \right] + h(y) d(g y, T x) \quad \forall x, y \in K,$$

(22)
There exist a function \( h : K \to [0, \infty) \) and \( \gamma \in [0, 1/2) \) such that
\[
H(Tx, Ty \cap K) \leq \gamma \left[ d(x, Tx \cap K) + d(y, Ty \cap K) \right] + h(y) d(gy, Tx \cap K) \quad \forall x, y \in K, \tag{23}
\]

Then \( C \mathcal{O} \mathcal{P}_K(g, T) \cap \mathcal{F}_K(T) \neq \emptyset. \)

**Proof.** It is obvious that any of these conditions (K1)–(K7) implies condition (D3) as in Theorem 8. So the desired conclusion follows from Theorem 8 immediately. \( \square \)

The following fixed point theorem for multivalued non-self-maps of generalized Kannan type can be established immediately from Theorem 9 for \( g \equiv id \) (the identity mapping).

**Theorem 10.** Let \( (X, d) \) be a complete metric space, \( K \) a nonempty closed subset of \( X \), and \( T : K \to CB(X) \) a multivalued map. Suppose that \( Tx \cap K \neq \emptyset \) for all \( x \in K \) and one of the following conditions holds:

(P1) there exist a function \( h : K \to [0, \infty) \) and \( \gamma \in [0, 1/2) \) such that
\[
H(Tx, Ty \cap K) \leq \gamma \left[ d(x, Tx \cap K) + d(y, Ty \cap K) \right] + h(y) d(y, Tx \cap K) \quad \forall x, y \in K, \tag{29}
\]

(P2) there exist a function \( h : K \to [0, \infty) \) and \( \gamma \in [0, 1/2) \) such that
\[
H(Tx, Ty \cap K) \leq \gamma \left[ d(x, Tx \cap K) + d(y, Ty \cap K) \right] + h(y) d(y, Ty \cap K) \quad \forall x, y \in K, \tag{30}
\]

(P3) there exist a function \( h : K \to [0, \infty) \) and \( \gamma \in [0, 1/2) \) such that
\[
H(Tx, Ty \cap K) \leq \gamma \left[ d(x, Tx \cap K) + d(y, Ty \cap K) \right] + h(y) d(y, Ty \cap K) \quad \forall x, y \in K, \tag{31}
\]

(P4) there exist a function \( h : K \to [0, \infty) \) and \( \gamma \in [0, 1/2) \) such that
\[
H(Tx, Ty \cap K) \leq \gamma \left[ d(x, Tx \cap K) + d(y, Ty \cap K) \right] + h(y) d(y, Ty \cap K) \quad \forall x, y \in K, \tag{32}
\]

(P5) there exist a function \( h : K \to [0, \infty) \) and \( \gamma \in [0, 1/2) \) such that
\[
H(Tx, Ty \cap K) \leq \gamma \left[ d(x, Tx \cap K) + d(y, Ty \cap K) \right] + h(y) d(y, Ty \cap K) \quad \forall x, y \in K, \tag{33}
\]

(P6) there exist a function \( h : K \to [0, \infty) \) and \( \gamma \in [0, 1/2) \) such that
\[
H(Tx, Ty \cap K) \leq \gamma \left[ d(x, Tx \cap K) + d(y, Ty \cap K) \right] + h(y) d(y, Ty \cap K) \quad \forall x, y \in K, \tag{34}
\]
(P7) there exist a function \( h : K \to [0, \infty) \) and \( \gamma \in [0,1/2) \) such that
\[
\mathcal{H}(Tx,Ty \cap K) \\
\leq \gamma [d(x,Tx) + d(y,Tx) + d(y,Ty \cap K)] + h(y)d(y,Tx \cap K) \quad \forall x,y \in K,
\]
\[
(35)
\]

(P8) there exist a function \( h : K \to [0, \infty) \) and \( \gamma \in [0,1/2) \) such that
\[
\mathcal{H}(Tx,Ty \cap K) \\
\leq \gamma [d(x,Tx) + d(y,Tx) + d(y,Ty \cap K)] + h(y)d(y,Tx \cap K) \quad \forall x,y \in K.
\]
\[
(36)
\]

Proof. Let \( x \in K \). Since \( \alpha \in [0,1/2) \), by the denseness of \( \mathbb{R} \), we can find \( \beta > 0 \) such that \( \alpha < \beta < 1/2 \). Let \( y \in Tx \cap K \) be arbitrary. Then \( d(y,Tx \cap K) = 0 \). By (D2), we have \( d(gy,Tx \cap K) = 0 \). Hence (38) has been reduced to
\[
d(y,Ty \cap K) \leq \mathcal{H}(Tx,Ty \cap K) \\
\leq \alpha d(x,Ty \cap K) + h(y)d(y,Tx \cap K) \quad \forall x,y \in K.
\]
\[
(38)
\]

This implies \( \mathcal{H}(K,T) \) is nonempty closed subset of \( X \). Suppose that \( x \in K \). If \( x = Tx \cap K \), then \( x \in F(T) \) and hence \( g_1 \in T \). Hence \( x \in \mathcal{K}(K,T) \) and the proof is finished. Otherwise, if \( x \neq Tx \cap K \), then \( d(x,Tx) > 0 \). By (39), we have
\[
d(x,Tx \cap K) < \beta d(x,Tx \cap K),
\]
which implies that there exists \( x \in T \cap K \) such that
\[
d(x,Tx \cap K) < \beta d(x,Tx \cap K) \leq \beta d(x,Tx \cap K) \leq \beta [d(x,x_1) + d(x_1,Tx \cap K)]
\]
\[
(40)
\]

Continuing in this way, we can construct inductively a sequence \( \{x_n\}_{n \in \mathbb{N}} \) in \( X \) satisfying
\[
x_{n+1} \in T x_n \cap K,
\]
\[
d(x_{n+1},x_n) < \gamma d(x_n,x_{n+1})
\]
for each \( n \in \mathbb{N} \). Using a similar argument as in the proof of Theorem 8, we have the following:

(i) \( x_{n+1} \in Tx_n \cap K \);
(ii) \( \{x_n\} \) is a Cauchy sequence in \( K \);
(iii) there exists \( x \in K \) such that \( x_n \to x \) as \( n \to \infty \);
(iv) \( gTx_n \cap K \) for each \( n \in \mathbb{N} \);
(v) \( \lim_{n \to \infty} gTx_n = g x \).

By (38), we get
\[
d(v,Tv \cap K) \\
= \lim_{n \to \infty} d(x_{n+1},Tv \cap K) \\
\leq \lim_{n \to \infty} \mathcal{H}(Tx_{n+1},Tv \cap K) \\
\leq \lim_{n \to \infty} \mathcal{H}(Tx_n,Tv \cap K) \\
\leq \lim_{n \to \infty} [\alpha [d(x_n,Tv \cap K) + d(v,Tx_n \cap K)] + h(v)d(g(Tx_n \cap K))] \\
\leq \lim_{n \to \infty} [\alpha [d(x_{n+1},Tv \cap K) + d(v,x_{n+1})] + h(v)d(gTv,gx_{n+1})] \\
= ad(v,Tv \cap K),
\]
which implies \( d(v,Tv \cap K) = 0 \). By the closedness of \( Tv \), we have \( v \in Tv \cap K \). By (D2), \( gTv \subseteq Tv \cap K \) and hence \( v \in \mathcal{K}(K,T) \). The proof is complete. 

\[
\square
\]
Theorem 14. In Theorem 13, if inequality (38) is replaced with one of the following inequalities:

(C1) \[ H(Tx, Ty \cap K) \leq \alpha [d(x, Ty) + d(y, Tx)] + h(y) d(gy, Tx) \quad \forall x, y \in K, \]

(C2) \[ H(Tx, Ty \cap K) \leq \alpha [d(x, Ty) + d(y, Tx)] + h(y) d(gy, Tx \cap K) \quad \forall x, y \in K, \]

(C3) \[ H(Tx, Ty \cap K) \leq \alpha [d(x, Ty) + d(y, Tx)] + h(y) d(gy, Tx \cap K) \quad \forall x, y \in K, \]

(C4) \[ H(Tx, Ty \cap K) \leq \alpha [d(x, Ty) + d(y, Tx)] + h(y) d(gy, Tx) \quad \forall x, y \in K, \]

(C5) \[ H(Tx, Ty \cap K) \leq \alpha [d(x, Ty) + d(y, Tx)] + h(y) d(gy, Tx \cap K) \quad \forall x, y \in K, \]

(C6) \[ H(Tx, Ty \cap K) \leq \alpha [d(x, Ty) + d(y, Tx)] + h(y) d(gy, Tx) \quad \forall x, y \in K, \]

(C7) \[ H(Tx, Ty \cap K) \leq \alpha [d(x, Ty) + d(y, Tx)] + h(y) d(gy, Tx) \quad \forall x, y \in K, \]

then \( CE \mathcal{P}_K(g, T) \cap \mathcal{F}_K(T) \neq \emptyset. \)

Applying Theorem 14, we can prove the following fixed point theorems for multivalued maps of generalized Chatterjea type.

Theorem 15. Let \((X, d)\) a complete metric space, \(K\) a nonempty closed subset of \(X\), and \(T : K \rightarrow \mathcal{CB}(X)\) a multivalued map. Suppose that \(Tx \cap K \neq \emptyset\) for all \(x \in K\) and one of the following conditions holds:

(Q1) there exist a function \(h : K \rightarrow [0, \infty)\) and \(y \in [0, 1/2)\) such that

\[ H(Tx, Ty \cap K) \leq \alpha [d(x, Ty) + d(y, Tx)] + h(y) d(y, Tx) \quad \forall x, y \in K, \]

(Q2) there exist a function \(h : K \rightarrow [0, \infty)\) and \(y \in [0, 1/2)\) such that

\[ H(Tx, Ty \cap K) \leq \alpha [d(x, Ty \cap K) + d(y, Tx)] + h(y) d(y, Tx) \quad \forall x, y \in K, \]

(Q3) there exist a function \(h : K \rightarrow [0, \infty)\) and \(y \in [0, 1/2)\) such that

\[ H(Tx, Ty \cap K) \leq \alpha [d(x, Ty \cap K) + d(y, Tx)] + h(y) d(y, Tx \cap K) \quad \forall x, y \in K, \]

(Q4) there exist a function \(h : K \rightarrow [0, \infty)\) and \(y \in [0, 1/2)\) such that

\[ H(Tx, Ty \cap K) \leq \alpha [d(x, Ty) + d(y, Tx)] + h(y) d(y, Tx \cap K) \quad \forall x, y \in K, \]

(Q5) there exist a function \(h : K \rightarrow [0, \infty)\) and \(y \in [0, 1/2)\) such that

\[ H(Tx, Ty \cap K) \leq \alpha [d(x, Ty) + d(y, Tx \cap K)] + h(y) d(y, Tx) \quad \forall x, y \in K, \]

(Q6) there exist a function \(h : K \rightarrow [0, \infty)\) and \(y \in [0, 1/2)\) such that

\[ H(Tx, Ty \cap K) \leq \alpha [d(x, Ty \cap K) + d(y, Tx)] + h(y) d(y, Tx \cap K) \quad \forall x, y \in K, \]

(Q7) there exist a function \(h : K \rightarrow [0, \infty)\) and \(y \in [0, 1/2)\) such that

\[ H(Tx, Ty \cap K) \leq \alpha [d(x, Ty) + d(y, Tx)] + h(y) d(y, Tx \cap K) \quad \forall x, y \in K, \]
(Q8) there exist a function $h: K \to [0, \infty)$ and $\gamma \in (0, 1/2)$ such that
\[
\mathcal{H}(Tx, Ty \cap K) \leq \alpha [d(x, Ty) + d(y, Tx)] + h(y) d(y, Tx) \quad \forall x, y \in K.
\]
(59)

Define \(\kappa: [0, \infty) \to [0, 1]\) by \(\kappa(t) = (1 + \varphi(t))/2\). Then, by Lemma 18, \(\kappa\) is also an \(\mathcal{MT}\)-function. Let \(x \in K\) be given. Take \(x_1 = x\). Since \(Tx_1 \cap K \neq 0\) from (D1), we can choose \(x_2 \in Tx_1 \cap K\). If \(x_2 = x_1\), then \(x_1 \in \mathcal{F}_K(T)\) and hence \(gx_1 \in Tx_1\) from (D2). Thus, \(x_1 \in C\mathcal{OP}_\kappa(g, T) \cap \mathcal{F}_K(T)\) and hence we achieved the result. Now, suppose that \(x_2 \neq x_1\); that is, \(d(x_1, x_2) > 0\). By (62), we have
\[
d(x_2, Tx_2 \cap K) \leq \varphi(d(x_1, x_2)) d(x_1, x_2) < \kappa(d(x_1, x_2)) d(x_1, x_2),
\]
(63)

which implies that there exists \(x_3 \in Tx_2 \cap K\) such that
\[
d(x_2, x_3) < \kappa(d(x_1, x_2)) d(x_1, x_2).
\]
(64)

Next, by (62) again, there exists \(x_4 \in Tx_3 \cap K\) such that
\[
d(x_3, x_4) < \kappa(d(x_2, x_3)) d(x_2, x_3).
\]
(65)

Iteratively, we can obtain a sequences \(\{x_n\}\) in \(K\) satisfying
\[
x_{n+1} \in Tx_n \cap K, \quad d(x_{n+1}, x_{n+2}) < \kappa(d(x_n, x_{n+1})) d(x_n, x_{n+1}) \quad \forall n \in \mathbb{N}.
\]
(66)

(67)

Let \(y := \sup_{n \in \mathbb{N}}\kappa(d(x_n, x_{n+1}))\). So \(y \in (0, 1)\). By (67), we have
\[
d(x_{n+1}, x_{n+2}) \leq \varphi(d(x_n, x_{n+1})) d(x_n, x_{n+1}) \leq \gamma d(x_n, x_{n+1}) < \gamma^2 d(x_{n-1}, x_n) < \ldots < \gamma^n d(x_1, x_2), \quad \text{for } n \in \mathbb{N}.
\]

Let \(\alpha_n = (y^{n+1}/(1 - y))d(x_1, x_2), n \in \mathbb{N}\). For \(m, n \in \mathbb{N}\) with \(m > n\), we have
\[
d(x_m, x_n) \leq \sum_{j=n}^{m-1} d(x_j, x_{j+1}) < \alpha_n.
\]
(70)

Since \(0 < y < 1\), \(\lim_{n \to \infty} \alpha_n = 0\) and hence \(\lim_{n \to \infty} \sup\{d(x_n, x_m) : m > n\} = 0\). This proves that \(\{x_n\}\) is a Cauchy sequence in \(K\). By the completeness of \(K\), there exists \(v \in K\) such that \(x_n \to v\) as \(n \to \infty\). Thanks to (66) and (D2), we have
\[
gx_{n+1} \in Tx_n \cap K \quad \text{for each } n \in \mathbb{N}.
\]
(71)

Since \(g\) is continuous and \(\lim_{n \to \infty} gx_n = v\), we have
\[
\lim_{n \to \infty} gx_n = gv.
\]
(72)
Since the function $x \mapsto d(x, Tv)$ is continuous, by (61), (66), and (72), we get
\[
d(v, Tv \cap K) = \lim_{n \to \infty} d(x_{n+1}, Tv \cap K)
\leq \lim_{n \to \infty} \mathcal{H}(Tx_n, Tv \cap K)
\leq \lim_{n \to \infty} \mathcal{H}(x_n, v) d(x_n, v)
\]
which implies $d(v, Tv \cap K) = 0$. By the closedness of $Tv$, we have $v \in Tv \cap K$. By (D2), $g v \in Tv \cap K \subseteq Tv$ and hence $v \in COP_{K}(g, T) \cap F_{K}(T)$. The proof is complete. \hfill \Box

**Theorem 20.** In Theorem 19, if inequality (61) is replaced with the following inequality:
\[
\mathcal{H}(Tx, Ty \cap K) \leq \varphi(d(x, y)) d(x, y) + h(y) d(gy, Tx) \quad \forall x, y \in K.
\]
Then $COP_{K}(g, T) \cap F_{K}(T) \neq \emptyset$.

**Corollary 21.** Let $(X, d)$ be a complete convex metric space, $K$ a nonempty closed subset of $X$, $T : K \to \mathcal{BC}(X)$ a multivalued map, and $g : K \to X$ a continuous self-map. Suppose that

(i) $Tx \cap K \neq \emptyset$ for all $x \in K$,
(ii) $Tx \cap K$ is $g$-invariant (i.e., $g(Tx \cap K) \subseteq Tx \cap K$) for each $x \in K$,
(iii) there exist an $\mathcal{M}_{T}$-function $\varphi : [0, \infty) \to [0, 1)$ and $L \geq 0$ such that
\[
\mathcal{H}(Tx, Ty \cap K) \leq \varphi(d(x, y)) d(x, y) + Ld(gy, Tx) \quad \forall x, y \in K.
\]
Then $COP_{K}(g, T) \cap F_{K}(T) \neq \emptyset$.

**Corollary 22.** Let $(X, d)$ be a complete convex metric space, $K$ a nonempty closed subset of $X$, $T : K \to \mathcal{BC}(X)$ a multivalued map, and $g : K \to X$ a continuous self-map. Suppose that

(i) $Tx \cap K \neq \emptyset$ for all $x \in K$,
(ii) $Tx \cap K$ is $g$-invariant (i.e., $g(Tx \cap K) \subseteq Tx \cap K$) for each $x \in K$,
(iii) there exist an $\mathcal{M}_{T}$-function $\varphi : [0, \infty) \to [0, 1)$ and $L \geq 0$ such that
\[
\mathcal{H}(Tx, Ty \cap K) \leq \varphi(d(x, y)) d(x, y) + Ld(gy, Tx) \quad \forall x, y \in K.
\]
Then $COP_{K}(g, T) \cap F_{K}(T) \neq \emptyset$.

As a direct consequence of Theorems 19 and 20, we obtain the following fixed point result for multivalued non-self-maps of Du type in complete metric spaces.

**Theorem 23.** Let $(X, d)$ be a complete convex metric space, $K$ a nonempty closed subset of $X$, and $T : X \to \mathcal{BC}(X)$ a multivalued map. Suppose that $Tx \cap K \neq \emptyset$ for all $x \in K$, and one of the following conditions holds:

(W1) there exist an $\mathcal{M}_{T}$-function $\varphi : [0, \infty) \to [0, 1)$ and a function $h : K \to [0, \infty)$ such that
\[
\mathcal{H}(Tx, Ty \cap K) \leq \varphi(d(x, y)) d(x, y) + h(y) d(gy, Tx) \quad \forall x, y \in K,
\]
(W2) there exist an $\mathcal{M}_{T}$-function $\varphi : [0, \infty) \to [0, 1)$ and a function $h : K \to [0, \infty)$ such that
\[
\mathcal{H}(Tx, Ty \cap K) \leq \varphi(d(x, y)) d(x, y) + h(y) d(gy, Tx) \quad \forall x, y \in K.
\]
Then $F_{K}(T) \neq \emptyset$.

**Proof.** Let $g = \text{id}$ be the identity map. It is easy to verify that all the conditions of Theorem 19 (or Theorem 20) are satisfied. Hence the conclusion follows from Theorem 19 (or Theorem 20).

The following fixed point theorems for multivalued non-self-maps of generalized Berinde-Berinde type and generalized Mizoguchi-Takahashi type are established immediately from Theorem 23.

**Corollary 24.** Let $(X, d)$ be a complete convex metric space, $K$ a nonempty closed subset of $X$, and $T : K \to \mathcal{BC}(X)$ a multivalued map. Suppose that

(i) $Tx \cap K \neq \emptyset$ for all $x \in K$,
(ii) there exist an $\mathcal{M}_{T}$-function $\varphi : [0, \infty) \to [0, 1)$ and $L \geq 0$ such that
\[
\mathcal{H}(Tx, Ty \cap K) \leq \varphi(d(x, y)) d(x, y) + Ld(y, Tx) \quad \forall x, y \in K.
\]
Then $F_{K}(T) \neq \emptyset$.

**Corollary 25.** Let $(X, d)$ be a complete convex metric space, $K$ a nonempty closed subset of $X$, and $T : K \to \mathcal{BC}(X)$ a multivalued map. Suppose that

(i) $Tx \cap K \neq \emptyset$ for all $x \in K$,
(ii) there exist an $\mathcal{M}_{T}$-function $\varphi : [0, \infty) \to [0, 1)$ and $L \geq 0$ such that
\[
\mathcal{H}(Tx, Ty \cap K) \leq \varphi(d(x, y)) d(x, y) + Ld(y, Tx) \quad \forall x, y \in K.
\]
Then $F_{K}(T) \neq \emptyset$. 

\[
(80)
\]

\[
(81)
\]
Corollary 26. Let \((X, d)\) be a complete convex metric space, \(K\) a nonempty closed subset of \(X\), and \(T : K \rightarrow 2^X\) a multivalued map. Suppose that

(i) \(Tx \cap K \neq \emptyset\) for all \(x \in K\),

(ii) there exists an \(M\)-\(\mathcal{F}\)-function \(\varphi : [0, \infty) \rightarrow [0, 1)\) such that

\[
\mathcal{F}(Tx, Ty \cap K) \leq \varphi(d(x, y))d(x, y) \quad \forall x, y \in K.
\]

Then \(\mathcal{F}_K(T) \neq \emptyset\).

Remark 27. (a) If \(K = X\) in Theorem 23, then we can obtain Du’s fixed point theorem \[12, \text{Theorem 2.6}\].

(b) Theorems 19, 20 and 23, and Corollaries 21–26 all generalize and improve Du’s fixed point theorem, Berinde-Berinde’s fixed point theorem, Mizoguchi-Takahashi’s fixed point theorem, Nadler’s fixed point theorem, and Banach’s contraction principle.

This paper deals with design algorithms for the split variational inequality and equilibrium problems. Strong convergence theorems are demonstrated.

1. Introduction

Let $H$ be a real Hilbert space. Let $C$ and $Q$ be two nonempty closed convex subsets of $H$. Consider the following problem.

Problem 1. Find a point $u^* \in C$ such that
\[
\Psi(u^*) \in Q.
\]

This problem is called split feasibility problem when $\Psi$ is a bounded linear operator. In this case, Problem 1 can be applied to many practical problems such as signal processing and image reconstruction. Specifically, we can find the prototype of Problem 1 in intensity-modulated radiation therapy; see, for example, [1–3]. Based on this relation, many mathematicians were devoted to study the split feasibility problem and develop its iterative algorithms. Related works can be found in [4–8] and the references therein.

Let $\mathcal{A}, \mathcal{B} : C \to H$ be two mappings. Consider the variational inequality of finding $u^* \in C, \Psi(u^*) \in C$ such that
\[
\langle \mathcal{A}u^*, \Psi(u) - \Psi(u^*) \rangle \geq 0,
\]
for all $\Psi(u) \in C$. We use $VI(\mathcal{A}, \Psi)$ to denote the set of solutions of (2). Variational inequality problems have important applications in many fields such as elasticity, optimization, economics, transportation, and structural analysis, and various numerical methods have been studied by many researchers; see, for instance, [9–17].

Let $\varphi : C \times C \to \mathbb{R}$ be an equilibrium bifunction; that is, $\varphi(u, u) = 0$ for each $u \in C$. Consider the equilibrium problem which is to find $u^* \in C$ such that
\[
\varphi(u^*, v) \geq 0, \quad \forall v \in C.
\]

Denote the set of solutions of (3) by $EP(\varphi, C)$. The equilibrium problems include fixed point problems, optimization problems, and variational inequality problems as special cases. Some algorithms have been proposed to solve the equilibrium problems; see, for example, [18–22]. Thus it is an interesting topic associated with algorithmic approach to the variational inequality and equilibrium problems. In this paper, our main purpose is to study the following split problem involved in the variational inequality and equilibrium problems. Find a point $x^1$ such that
\[
x^1 \in VI(\mathcal{A}, \Psi), \quad \Psi(x^1) \in EP(\varphi, C).
\]

We are devoted to study (4) with operator $\Psi$ being a nonlinear mapping. For this purpose, we develop an iterative algorithm for solving the split problem (4). We can compute $x^1$ iteratively by using our algorithm. Convergence analysis is given under some mild assumptions.

2. Basic Concepts

Let $C$ be a nonempty closed convex subset of a real Hilbert space $H$. An operator $\mathcal{B} : C \to H$ is said to be

(i) monotone $\Rightarrow \langle u - v, \mathcal{B}u - \mathcal{B}v \rangle \geq 0$ for all $u, v \in C$;
In the sequel, we use Fix\( \text{Fix} \)· Let \( A \) be a nonempty closed convex subset of a real Hilbert space \( H \). Assume that \( u \in A \), then we can deduce that \( \text{proj}_H u \)-inverse strongly monotone.

### 3. Useful Lemmas

In this section, we present several lemmas which will be used in the next section.

**Lemma 2** (see [19]). Let \( C \) be a nonempty closed convex subset of a real Hilbert space \( H \). Let \( \varphi : C \times C \to \mathbb{R} \) be a bifunction. Assume that \( \varphi \) satisfies the following conditions:

\[
\tag{5} \langle x - \text{proj}_C x, y - \text{proj}_C x \rangle \leq 0.
\]

for all \( x \in H \) and \( y \in C \). From this characteristic inequality, we can deduce that \( \text{proj}_C \) is firmly nonexpansive.

Set \( \mathcal{F}_\varphi(u) = \{ w \in C : \varphi(w, v) + (1/\alpha) \langle v - w, w - u \rangle \geq 0 \text{ for all } v \in C \} \). Then one have the following:

(i) \( \mathcal{F}_\varphi \) is single valued and \( \mathcal{F}_\varphi \) is firmly nonexpansive,

(ii) \( \mathcal{F}(\varphi, C) \) is closed and convex and \( \mathcal{F}(\varphi, C) = \text{Fix}(\mathcal{F}_\varphi) \).

**Lemma 3** (see [23]). Let \( C \) be a nonempty closed convex subset of a real Hilbert space \( H \). For \( x \in H \), let the mapping \( \mathcal{F}_\varphi \) be the same as in Lemma 2. Then for \( \mu > 0 \) and \( x \in H \), one has

\[
\tag{7} \| F_\mu (x) - F_\mu (x) \|^2 \leq \frac{\mu - v}{\mu} \langle F_\mu (x) - F_\mu (y), F_\mu (x) - y \rangle.
\]

**Lemma 4** (see [24]). Let \( \{u_n\} \) and \( \{v_n\} \) be two bounded sequences in \( [0, 1] \) satisfying \( 0 < \inf_{n \to \infty} \frac{\sum_{\delta = 0}^n \kappa_n \varsigma_n}{\sum_{\delta = 0}^n \kappa_n} \leq \limsup_{n \to \infty} \frac{\sum_{\delta = 0}^n \kappa_n \varsigma_n}{\sum_{\delta = 0}^n \kappa_n} < 1 \). Suppose \( u_{n+1} = (1 - \kappa_n)w_n + \kappa_n u_n \) for all \( n \geq 0 \) and \( \limsup_{n \to \infty} \| v_n - v_n \| - \| u_{n+1} - u_n \| \) \( \leq 0 \). Then, \( \lim_{n \to \infty} \| u_n - v_n \| = 0 \).

**Lemma 5** (see [25]). Let \( C \) be a nonempty closed convex subset of a real Hilbert space \( H \). Let \( \mathcal{S} : C \to C \) be a nonexpansive mapping with \( \text{Fix}(\mathcal{S}) \neq \emptyset \). Then \( \mathcal{S} \) is demiclosed on \( C \).

**Lemma 6** (see [26]). Let \( \{a_n\} \subset [0, \infty) \) be a sequence. Assume that \( a_{n+1} \leq (1 - \gamma_n)a_n + \gamma_n \), where \( \{\gamma_n\} \) is a sequence in \( (0, 1) \), and \( \{\delta_n\} \) is a sequence satisfying \( \sum_{n=1}^\infty \gamma_n = \infty \) and \( \limsup_{n \to \infty} \delta_n \leq 0 \) \( (\text{or } \sum_{n=1}^\infty |\delta_n| \gamma_n < \infty) \). Then \( \lim_{n \to \infty} \gamma_n = 0 \).

### 4. Main Results

In this section, we firstly present our problem and algorithm constructed. Consequently, we give the convergence analysis of the presented algorithm.

**Problem 7.** Let \( C \) be a nonempty closed convex subset of a real Hilbert space \( H \). Assume that

\[
\tag{1} \Psi : C \to C \text{ is weakly continuous and } \zeta \text{-strongly monotone mapping such that } R(\Psi) = C; \\
\tag{2} A : C \to H \text{ is an } \zeta \text{-inverse strongly } \Psi \text{-monotone mapping;} \\
\tag{3} \varphi : C \times C \to \mathbb{R} \text{ is a bifunction satisfying conditions}\ 
\tag{F1} - \tag{F4} \text{ in Lemma 2.}
\]

Our objective is to find \( x^* \in VI(A, \Psi) \) such that \( \Psi(x^*) \in \text{EP}(\varphi, C) \). 

We use \( Y \) to denote the set of solutions of (8). In the following, we assume that \( Y \) is nonempty. For solving Problem 7, we introduce the following algorithm.

**Algorithm 8.**

**Step 0 (initialization).** Let \( u_0 \in C \).
Step 1. For given \( \{u_n\} \), let the sequence \( \{v_n\} \) be generated iteratively by
\[
v_n = \text{proj}_C (\Psi(u_n) - \mu_n \Lambda u_n), \quad n \geq 0,
\]
where \( \text{proj}_C \) is the metric projection and \( \{u_n\} \) is a real number sequence.

Step 2. For given \( \{v_n\} \), find \( \{z_n\} \) such that
\[
\varrho (z_n, y) + \frac{1}{\alpha_n} \langle y - z_n, z_n - (1 - \alpha_n) v_n \rangle \geq 0, \quad \forall y \in C,
\]
where \( \alpha_n \subset (0, \infty) \) and \( \alpha_n \subset [0, 1] \) are two real number sequences.

Step 3. For the previous sequences \( \{u_n\} \) and \( \{z_n\} \), let the \( (n + 1) \)th sequence \( \{u_{n+1}\} \) be generated by
\[
\Psi (u_{n+1}) = \kappa_n \Psi (u_n) + (1 - \kappa_n) z_n, \quad n \geq 0,
\]
where \( \kappa_n \subset [0, 1] \) is a real number sequence.

**Theorem 9.** Assume that the following conditions are satisfied:

(C1) \( \lim_{n \to \infty} \alpha_n = 0 \) and \( \sum_n \alpha_n = \infty; \)
(C2) \( 0 < \liminf \alpha_n, \kappa_n \leq \limsup \alpha_n, \kappa_n < 1; \)
(C3) \( \omega_n \subset (\eta_1, \eta_2) \subset (0, \infty), \mu_n \subset (\xi_1, \xi_2) \subset (0, 2c), \)
and \( \zeta \subset (0, 2c); \)
(C4) \( \lim_{n \to \infty} (\mu_{n+1} - \mu_n) = 0 \) and \( \lim_{n \to \infty} (\alpha_{n+1} - \alpha_n) = 0. \)

Then the sequence \( \{u_n\} \) generated by Algorithm 8 converges strongly to \( x^* \in \mathcal{Y}. \)

**Proof.** Let \( \hat{x} \in \mathcal{Y}. \) Hence \( \hat{x} \in \mathcal{V}(\Lambda, \Psi) \) and \( \Psi(\hat{x}) \in \mathcal{EP}(\emptyset, C) \), noting that \( \hat{x} \in \mathcal{V}(\Lambda, \Psi) \) implies \( \Psi(\hat{x}) = \text{proj}_C (\Psi(\hat{x}) - v/\Lambda \hat{x}) \) for all \( v > 0. \) Hence \( \Psi(\hat{x}) = \text{proj}_C (\Psi(\hat{x}) - \mu_n \Lambda \hat{x}) \) for all \( n \geq 0. \) Thus, from (10), we have
\[
\left\| v_n - \Psi (\hat{x}) \right\|^2 = \left\| \text{proj}_C (\Psi (u_n) - \mu_n \Lambda u_n) - \text{proj}_C (\Psi (\hat{x}) - \mu_n \Lambda \hat{x}) \right\|^2
\]
\[
\leq \left\| (\Psi (u_n) - \mu_n \Lambda u_n) - (\Psi (\hat{x}) - \mu_n \Lambda \hat{x}) \right\|^2
\]
\[
= \left\| (\Psi (u_n) - \Psi (\hat{x})) \right\|^2 - 2 \mu_n \langle \Lambda u_n - \Lambda \hat{x}, \Psi (u_n) - \Psi (\hat{x}) \rangle
\]
\[
+ \mu_n \langle \Lambda u_n - \Lambda \hat{x}, \Psi (u_n) - \Psi (\hat{x}) \rangle
\]
\[
\leq \left\| (\Psi (u_n) - \Psi (\hat{x})) \right\|^2 - 2 \mu_n \zeta \langle \Lambda u_n - \Lambda \hat{x}, \Psi (u_n) - \Psi (\hat{x}) \rangle
\]
\[
+ \mu_n \langle \Lambda u_n - \Lambda \hat{x}, \Psi (u_n) - \Psi (\hat{x}) \rangle
\]
\[
\leq \left\| (\Psi (u_n) - \Psi (\hat{x})) \right\|^2 + \mu_n \langle \mu_n - 2 \zeta \rangle \left\| \Lambda u_n - \Lambda \hat{x} \right\|^2.
\]

Condition (C3) and (13) imply that
\[
\left\| v_n - \Psi (\hat{x}) \right\| \leq \left\| (\Psi (u_n) - \Psi (\hat{x})) \right\|.
\]

From Lemma 2 and (11), we get \( z_n = f_{\omega_n}(1 - \alpha_n) v_n \) for all \( n \geq 0. \) Since \( \Psi(\hat{x}) \in \mathcal{EP}(\emptyset, C) \), from Lemma 2 we deduce that \( \Psi(\hat{x}) = f_{\omega_n}(\Psi(\hat{x})) \) for all \( n \geq 0. \) So,
\[
\left\| z_n - \Psi (\hat{x}) \right\|
\]
\[
= \left\| f_{\omega_n}(1 - \alpha_n) v_n - f_{\omega_n}(\Psi (\hat{x})) \right\|
\]
\[
\leq \left\| (1 - \alpha_n) v_n - \Psi (\hat{x}) \right\|
\]
\[
\leq (1 - \alpha_n) \left\| v_n - \Psi (\hat{x}) \right\| + \alpha_n \left\| \Psi (\hat{x}) \right\|
\]
by (14)
\[
\leq (1 - \alpha_n) \left\| (\Psi (u_n) - \Psi (\hat{x})) \right\| + \alpha_n \left\| \Psi (\hat{x}) \right\|.
\]

It follows that
\[
\left\| (\Psi (u_n) - \Psi (\hat{x})) \right\|
\]
\[
\leq \kappa_n \left\| (\Psi (u_n) - \Psi (\hat{x})) \right\| + (1 - \kappa_n) \left\| z_n - \Psi (\hat{x}) \right\|
\]
\[
\leq \kappa_n \left\| (\Psi (u_n) - \Psi (\hat{x})) \right\|
\]
\[
+ (1 - \kappa_n) (1 - \alpha_n) \left\| (\Psi (u_n) - \Psi (\hat{x})) \right\|
\]
\[
+ (1 - \kappa_n) \alpha_n \left\| \Psi (\hat{x}) \right\|
\]
\[
= \left[ (1 - (1 - \kappa_n) \alpha_n) \left\| (\Psi (u_n) - \Psi (\hat{x})) \right\|
\]
\[
+ (1 - \kappa_n) \alpha_n \left\| \Psi (\hat{x}) \right\|
\]
\[
\right\|
\]
\[
\text{(16)}
\]

By induction
\[
\left\| (\Psi (u_n) - \Psi (\hat{x})) \right\| \leq \max \left\{ \left\| (\Psi (u_0) - \Psi (\hat{x})) \right\|, \left\| \Psi (\hat{x}) \right\| \right\}
\]
\[
\text{(17)}
\]

Hence, \( \{\Psi (u_n)\} \) is bounded. Since \( \Psi \) is \( \zeta \)-strongly monotone, we can get \( \zeta \left\| u_n - \hat{x} \right\| \leq \left\| \Psi (u_n) - \Psi (\hat{x}) \right\|. \) So, \( \left\| u_n - \hat{x} \right\| \leq (1/\zeta) \left\| \Psi (u_n) - \Psi (\hat{x}) \right\| \leq (1/\zeta) \max \left\{ \left\| (\Psi (u_0) - \Psi (\hat{x})) \right\|, \left\| \Psi (\hat{x}) \right\| \right\}. \)
This implies that \( \{u_n\} \) is bounded. Next, we show \( \left\| u_{n+1} - u_n \right\| \to 0. \) From \( z_n = f_{\omega_n}(1 - \alpha_n) v_n, \) we have
\[
\left\| z_{n+1} - z_n \right\|
\]
\[
= \left\| f_{\omega_{n+1}}(1 - \alpha_{n+1}) v_{n+1} - f_{\omega_n}(1 - \alpha_n) v_n \right\|
\]
\[
\leq \left\| f_{\omega_{n+1}}(1 - \alpha_{n+1}) v_{n+1} - f_{\omega_{n+1}}(1 - \alpha_n) v_n \right\|
\]
\[
+ \left\| f_{\omega_{n+1}}(1 - \alpha_n) v_n - f_{\omega_n}(1 - \alpha_n) v_n \right\|
\]
\[
\leq (1 - \alpha_{n+1}) v_{n+1} - (1 - \alpha_n) v_n
\]
\[
+ \left\| f_{\omega_{n+1}}(1 - \alpha_n) v_n - f_{\omega_n}(1 - \alpha_n) v_n \right\|
\]
\[
\text{(18)}
\]
Using Lemma 3, we obtain
\[
\|F_{\omega_{n+1}} (1 - \alpha_n) v_n - F_{\omega_n} (1 - \alpha_n) v_n\|^2 \\
\leq \frac{\omega_{n+1} - \omega_n}{\omega_n} \|F_{\omega_{n+1}} (1 - \alpha_n) v_n - F_{\omega_n} (1 - \alpha_n) v_n\| \\
\times \|F_{\omega_{n+1}} (1 - \alpha_n) v_n - (1 - \alpha_n) v_n\|.
\]

Then
\[
\|F_{\omega_{n+1}} (1 - \alpha_n) v_n - F_{\omega_n} (1 - \alpha_n) v_n\| \\
\leq \frac{\omega_{n+1} - \omega_n}{\omega_n} \|F_{\omega_{n+1}} (1 - \alpha_n) v_n - (1 - \alpha_n) v_n\|.
\]

By condition (C3), we have \(\omega_n > \eta_1 > 0\). So,
\[
\|z_{n+1} - z_n\| \\
\leq \|(1 - \alpha_{n+1}) v_{n+1} - (1 - \alpha_n) v_n\| + \frac{\omega_{n+1} - \omega_n}{\omega_n} \|F_{\omega_{n+1}} (1 - \alpha_n) v_n - (1 - \alpha_n) v_n\| \\
\times \|F_{\omega_{n+1}} (1 - \alpha_n) v_n - (1 - \alpha_n) v_n\| \\
\leq (1 - \alpha_{n+1}) \|v_{n+1} - v_n\| + \frac{\alpha_{n+1} - \alpha_n}{\eta_1} \|v_n\| \\
\times \|F_{\omega_{n+1}} (1 - \alpha_n) v_n - (1 - \alpha_n) v_n\|.
\]

Therefore,
\[
\|z_{n+1} - z_n\| \leq (1 - \alpha_{n+1}) \|\Psi (u_{n+1}) - \Psi (u_n)\| + |\alpha_{n+1} - \alpha_n| \|v_n\| + |\mu_{n+1} - \mu_n| \|\lambda (u_n)\| \\
+ \frac{1}{\eta_1} |\omega_{n+1} - \omega_n| \|F_{\omega_{n+1}} (1 - \alpha_n) v_n - (1 - \alpha_n) v_n\|.
\]

It follows that
\[
\|z_{n+1} - z_n\| - \|\Psi (u_{n+1}) - \Psi (u_n)\| \\
\leq |\alpha_{n+1} - \alpha_n| \|v_n\| + |\mu_{n+1} - \mu_n| \|\lambda (u_n)\| \\
+ \frac{1}{\eta_1} |\omega_{n+1} - \omega_n| \|F_{\omega_{n+1}} (1 - \alpha_n) v_n - (1 - \alpha_n) v_n\|.
\]

Since \(\lim_{n \to \infty} \alpha_n = 0\), \(\lim_{n \to \infty} (\mu_{n+1} - \mu_n) = 0\), and \(\lim_{n \to \infty} (\omega_{n+1} - \omega_n) = 0\) and the sequences \(\{\Psi (u_n)\}, \{z_n\}, \{v_n\}\), and \(\{\lambda (u_n)\}\) are bounded, we deduce that
\[
\limsup_{n \to \infty} (\|z_{n+1} - z_n\| - \|\Psi (u_{n+1}) - \Psi (u_n)\|) \leq 0.
\]

Applying Lemma 4, we obtain
\[
\lim_{n \to \infty} \|z_n - \Psi (u_n)\| = 0.
\]

Thus,
\[
\lim_{n \to \infty} \|\Psi (u_{n+1}) - \Psi (u_n)\| = \lim_{n \to \infty} (1 - \kappa_n) \|z_n - \Psi (u_n)\| = 0.
\]

This together with the \(\zeta\)-strong monotonicity of \(\Psi\) implies that
\[
\lim_{n \to \infty} \|u_{n+1} - u_n\| = 0.
\]

From (13) and (16), we derive
\[
\|\Psi (u_{n+1}) - \Psi (\tilde{x})\|^2 \\
\leq \kappa_n \|\Psi (u_n) - \Psi (\tilde{x})\|^2 + (1 - \kappa_n) \|z_n - \Psi (\tilde{x})\|^2 \\
\leq \kappa_n \|\Psi (u_n) - \Psi (\tilde{x})\|^2 + (1 - \kappa_n) \|z_n - \Psi (\tilde{x})\|^2 \\
\times \left[(1 - \alpha_n) \|v_n - \Psi (\tilde{x})\|^2 + \alpha_n \|\Psi (\tilde{x})\|^2 \right].
\]

\[
\begin{align*}
\leq (1 - \kappa_n) \\
\times \left[ (1 - \alpha_n) \| \Psi(u_n) - \mu_n \lambda u_n - (\Psi(\bar{x}) - \mu_n \lambda \bar{x}) \|^2 \\
+ \alpha_n \| \Psi(\bar{x}) \|^2 \right] + \kappa_n \| \Psi(u_n) - \Psi(\bar{x}) \|^2 \\
\leq \kappa_n \| \Psi(u_n) - \Psi(\bar{x}) \|^2 + (1 - \kappa_n) (1 - \alpha_n) \\
\times \left( \| \Psi(u_n) - \Psi(\bar{x}) \|^2 + \mu_n (\mu_n - 2\zeta) \| \lambda u_n - \lambda \bar{x} \|^2 \right) \\
+ \alpha_n \| \Psi(\bar{x}) \|^2 \\
\leq \| \Psi(u_n) - \Psi(\bar{x}) \|^2 \\
+ (1 - \kappa_n) (1 - \alpha_n) \mu_n (\mu_n - 2\zeta) \| \lambda u_n - \lambda \bar{x} \|^2 \\
+ \alpha_n \| \Psi(\bar{x}) \|^2. \\
\end{align*}
\]

Hence,

\[
\begin{align*}
(1 - \kappa_n) (1 - \alpha_n) \mu_n (2\zeta - \mu_n) \| \lambda u_n - \lambda \bar{x} \|^2 \\
\leq \| \Psi(u_n) - \Psi(\bar{x}) \|^2 - \| \Psi(u_{n+1}) - \Psi(\bar{x}) \|^2 \\
+ \alpha_n \| \Psi(\bar{x}) \|^2 \\
\leq (\| \Psi(u_n) - \Psi(\bar{x}) \| + \| \Psi(u_{n+1}) - \Psi(\bar{x}) \|) \\
\times \| \Psi(u_{n+1}) - \Psi(u_n) \| + \alpha_n \| \Psi(\bar{x}) \|^2. \\
\end{align*}
\]

(30)

Since \( \alpha_n \to 0, \) \( \| \Psi(u_{n+1}) - \Psi(u_n) \| \to 0, \) and \( \lim \inf_{n \to \infty} (1 - \kappa_n)(1 - \alpha_n) \mu_n (2\zeta - \mu_n) > 0, \) we obtain

\[
\lim_{n \to \infty} \| \lambda u_n - \lambda \bar{x} \| = 0. \\
\]

(31)

Set \( y_n = \Psi(u_n) - \mu_n \lambda u_n - (\Psi(\bar{x}) - \mu_n \lambda \bar{x}) \) for all \( n. \) By using the firm nonexpansivity of projection, we get

\[
\begin{align*}
v_n - \Psi(\bar{x}) = & \text{proj}_C (\Psi(u_n) - \mu_n \lambda u_n)^2 \\
- \text{proj}_C (\Psi(\bar{x}) - \mu_n \lambda \bar{x})^2 \\
\leq & \langle y_n, v_n - \Psi(\bar{x}) \rangle \\
= & \frac{1}{2} \left\{ \| y_n \|^2 + \| v_n - \Psi(\bar{x}) \|^2 - \| y_n - v_n + \Psi(\bar{x}) \|^2 \right\} \\
\leq & \frac{1}{2} \left\{ \| \Psi(u_n) - \Psi(\bar{x}) \|^2 + \| v_n - \Psi(\bar{x}) \|^2 \\
- \| \Psi(u_n) - v_n - \mu_n (\lambda u_n - \lambda \bar{x}) \|^2 \right\} \\
= & \frac{1}{2} \left\{ \| \Psi(u_n) - \Psi(\bar{x}) \|^2 + \| v_n - \Psi(\bar{x}) \|^2 \\
- \| \Psi(u_n) - v_n \|^2 - \mu_n^2 \| \lambda u_n - \lambda \bar{x} \|^2 \right\} \\
+ 2 \mu_n \langle \Psi(u_n) - v_n, \lambda u_n - \lambda \bar{x} \rangle. \\
\end{align*}
\]

(32)

It follows that

\[
\begin{align*}
\| v_n - \Psi(\bar{x}) \|^2 \leq & \| \Psi(u_n) - \Psi(\bar{x}) \|^2 - \| \Psi(u_n) - v_n \|^2 \\
+ 2 \mu_n \| \Psi(u_n) - v_n \| \lambda u_n - \lambda \bar{x}. \\
\end{align*}
\]

(33)

From (29) and (32), we have

\[
\begin{align*}
\| \Psi(u_{n+1}) - \Psi(\bar{x}) \|^2 \\
\leq & \kappa_n \| \Psi(u_n) - \Psi(\bar{x}) \|^2 + (1 - \kappa_n) \\
\times \left[ (1 - \alpha_n) \| v_n - \Psi(\bar{x}) \|^2 + \alpha_n \| \Psi(\bar{x}) \|^2 \right] \\
\leq & \kappa_n \| \Psi(u_n) - \Psi(\bar{x}) \|^2 + (1 - \alpha_n) (1 - \kappa_n) \\
\times \left( \| \Psi(u_n) - \Psi(\bar{x}) \|^2 + (1 - \alpha_n) (1 - \kappa_n) (\mu_n - 2\zeta) \| \lambda u_n - \lambda \bar{x} \|^2 \\
+ (1 - \kappa_n) \alpha_n \| \Psi(\bar{x}) \|^2 + 2 \mu_n (1 - \kappa_n) \\
\times \| \Psi(u_n) - v_n \| \lambda u_n - \lambda \bar{x} \| + \alpha_n \| \Psi(\bar{x}) \|^2. \\
\end{align*}
\]

(34)

Then, we obtain

\[
\begin{align*}
(1 - \kappa_n) \| \Psi(u_n) - v_n \|^2 \\
\leq & (\| \Psi(u_n) - \Psi(\bar{x}) \| + \| \Psi(u_{n+1}) - \Psi(\bar{x}) \|) \\
\times \| \Psi(u_{n+1}) - \Psi(u_n) \| + \alpha_n \| \Psi(\bar{x}) \|^2. \\
\end{align*}
\]

(35)

Since \( \lim_{n \to \infty} \alpha_n = 0, \) \( \lim_{n \to \infty} \| \Psi(u_{n+1}) - \Psi(u_n) \| = 0, \) and \( \lim_{n \to \infty} \| \lambda u_n - \lambda \bar{x} \| = 0, \) we deduce that

\[
\lim_{n \to \infty} \| \Psi(u_n) - v_n \| = 0. \\
\]

(36)

Next, we prove \( \limsup_{n \to \infty} \langle \Psi(x^*), v_n - \Psi(x^*) \rangle \geq 0, \) where \( x^* \) satisfies \((\text{GVI})\): \( \langle \Psi(x^*), \Psi(x) - \Psi(x^*) \rangle \geq 0, \) for all \( x \in Y \)

(note that \( \Psi \) is \( \zeta \)-strongly monotone; we can easily deduce that the solution of \((\text{GVI})\) is unique). We take a subsequence \( \{ v_{n_i} \} \) of \( \{ v_n \} \) such that

\[
\lim_{i \to \infty} \langle \Psi(x^*), v_{n_i} - \Psi(x^*) \rangle = \lim_{i \to \infty} \langle \Psi(x^*), \Psi(u_{n_i}) - \Psi(x^*) \rangle. \\
\]

(37)

By the boundedness of \( \{ u_n \}, \) we can choose a subsequence \( \{ u_{n_i} \} \) of \( \{ u_n \} \) such that \( u_{n_i} \to z \) weakly. For the convenience, we may assume that \( u_{n_i} \to z. \) This implies that \( \Psi(u_n) \to \Psi(z) \) due to the weak continuity of \( \Psi. \) Now, we show \( z \in Y. \) We firstly show \( \Psi(z) \in \text{EP}(\phi, C). \)
Note that $\omega_n \in (\eta_1, \eta_2)$, then we choose a subsequence $\{\omega_n\}_n$ such that $\lim_{n \to \infty} \omega_n = \omega \in (\eta_1, \eta_2)$. From (26) and (36), we deduce that $\|z_n - \omega_n\| = \|f_{\omega_n}(1 - \alpha_n)\omega_{n - 1} - \omega_n\| \to 0$. Thus, $\|z_n - \omega_n\| = \|f_{\omega_n}(1 - \alpha_n)\omega_{n - 1} - \omega_n\| \to 0$. From Lemma 2, we know that $f_{\omega_n}$ is nonexpansive. By demiclosed principle (Lemma 5), we get immediately that $\Psi(z) \in \text{Fix}(f_{\omega_n}) = \text{EP}(\emptyset, C)$.

Next, we prove $z \in V(\emptyset, \Psi)$. Set

$$R_v = \begin{cases} \beta_v + N_C(v), & v \in C, \\ \theta, & v \notin C. \end{cases}$$

By [27], we know that $R$ is maximal $\Psi$-monotone. Let $(v, w) \in G(\emptyset)$. Since $w - \beta_v \in N_C(v)$ and $u_n \in C$, we have $\langle \Psi(v) - \Psi(u_n), w - \beta_v \rangle \geq 0$. Noting that $v_n = \text{proj}_C(\Psi(u_n) - \mu_n \beta u_n)$, we get

$$\langle \Psi(v) - v_n, v_n - \Psi(u_n) - \mu_n \beta u_n \rangle \geq 0. \quad (39)$$

It follows that

$$\left\langle \Psi(v) - v_n, \frac{v_n - \Psi(u_n)}{\mu_n} + \beta u_n \right\rangle \geq 0. \quad (40)$$

Then,

$$\left\langle \Psi(v) - \Psi(u_n), w \right\rangle \geq \left\langle \Psi(v) - \Psi(u_n), \beta_v \right\rangle \\ \geq \left\langle \Psi(v) - \Psi(u_n), \beta v \right\rangle \\ = \left\langle \Psi(v) - v_n, \frac{v_n - \Psi(u_n)}{\mu_n} \right\rangle \\ - \left\langle \Psi(v) - v_n, \beta u_n \right\rangle \\ = \left\langle \Psi(v) - \Psi(u_n), \beta_v \right\rangle + \left\langle \Psi(v) - \Psi(u_n), \beta u_n \right\rangle + \left\langle \Psi(v) - v_n, \frac{v_n - \Psi(u_n)}{\mu_n} \right\rangle \\ - \left\langle \Psi(v) - v_n, \beta u_n \right\rangle \\ \geq \left\langle \Psi(v) - v_n, \frac{v_n - \Psi(u_n)}{\mu_n} \right\rangle \\ - \left\langle \Psi(u_n) - v_n, \beta u_n \right\rangle. \quad (41)$$

Since $\|\Psi(u_n) - v_n\| \to 0$ and $\Psi(u_n) \to \Psi(z)$, we deduce that $\langle \Psi(v) - \Psi(z), w \rangle \geq 0$ by taking $i \to \infty$ in (41). Thus, $z \in R^1 0$ by the maximal $\Psi$-monotonicity of $R$. Hence, $z \in V(\emptyset, \Psi)$. Therefore, $z \in Y$. From (37), we obtain

$$\limsup_{n \to \infty} \langle \Psi(x^*), v_n - \Psi(x^*) \rangle = \lim_{i \to \infty} \langle \Psi(x^*), \Psi(u_n) - \Psi(x^*) \rangle \quad (42)$$

From (12), we have

$$\|\Psi(u_{n+1}) - \Psi(x^*)\|^2 \leq \kappa_n \|\Psi(u_n) - \Psi(x^*)\|^2 + (1 - \kappa_n) \times \left( \|v_n - \Psi(x^*)\|^2 + 2\alpha_n (1 - \alpha_n) \langle \Psi(x^*), v_n - \Psi(x^*) \rangle \right)$$

$$= \left[ 1 - (1 - \kappa_n) \alpha_n \right] \|\Psi(u_n) - \Psi(x^*)\|^2 + (1 - \kappa_n) \alpha_n \left( \|\Psi(x^*)\| \|\Psi(x^*)\| + \alpha_n \right)^2 \right]. \quad (43)$$

Using Lemma 6, we conclude that $\Psi(u_n) \to \Psi(x^*)$, and hence $u_n \to x^*$. This completes the proof. \qed

We study the existence and uniqueness of coincidence point for nonlinear mappings of any number of arguments under a weak \((\psi, \varphi)\)-contractivity condition in partial metric spaces. The results we obtain generalize, extend, and unify several classical and very recent related results in the literature in metric spaces (see Aydi et al. (2011), Berinde and Borcut (2011), Gnana Bhaskar and Lakshmikantham (2006), Berzig and Samet (2012), Borcut and Berinde (2012), Choudhury et al. (2011), Karapınar and Luong (2012), Lakshmikantham and Ćirić (2009), Luong and Thuan (2011), and Roldán et al. (2012)) and in partial metric spaces (see Shatanawi et al. (2012)).

1. Introduction

The notion of coupled fixed point was introduced by Guo and Lakshmikantham [1] in 1987. In a recent paper, Gnana Bhaskar and Lakshmikantham [2] introduced the concept mixed monotone property for contractive operators of the form \(F : X \times X \rightarrow X\), where \(X\) is a partially ordered metric space, and then established some coupled fixed-point theorems. After that, many results appeared on coupled fixed-point theory in different contexts (see, e.g., [3–6]). Later, Berinde and Borcut [7] introduced the concept of tripled fixed point and proved tripled fixed-point theorems using mixed monotone mappings (see also [8–10]).

Very recently, Roldán et al. [11] proposed the notion of coincidence point between mappings in any number of variables and showed some existence and uniqueness theorems that extended the mentioned previous results for this kind of nonlinear mappings, not necessarily permuted or ordered, in the framework of partially ordered complete metric spaces, using a weaker contraction condition, that also generalized other works by Berzig and Samet [12], Karapınar and Berinde [13].

Partial metric spaces were firstly introduced by Matthews in [14] as an attempt to generalize the metric spaces by establishing the condition that the distance between a point to itself (which is not necessarily zero) is less or equal than the distance between that point and another point of the space. In the mentioned papers, Matthews studied topological properties of partial metric spaces and stated a modified version of a Banach contraction mapping principle on this kind of spaces. After Matthews’ pioneering work, the theory of partial metric spaces and particularly the field of fixed-point theorems have expansively been developed due to the increasing interest in this area and motivated by its possible applications (see [15, 16] and references therein).

In this paper, our main aim is to study a weaker contractivity condition for nonlinear mappings of any number of arguments. This condition can be particularized in a variety of forms that let us extend the previously mentioned results and other recent ones in this field (see [2, 5, 7, 9, 11, 12, 16–20]). We also notice that our results cannot be obtained by the very recent paper of Haghi et al. [21] (for more details see Remark 26).

2. Preliminaries

Preliminaries and notation about coincidence points can also be found in [11]. Let \(n\) be a positive integer. Henceforth, \(X\) will denote a nonempty set, and \(X^n\) will denote the product space
X^n = X \times X \times \ldots \times X. Throughout this paper, m and k will denote nonnegative integers and i, j, s \in \{1, 2, \ldots, n\}. Unless otherwise stated, "for all m" will mean "for all m \geq 0", and "for all i" will mean "for all i \in \{1, 2, \ldots, n\}. Let \mathbb{R}_0^+ = [0, \infty].

A metric on X is a mapping d : X \times X \to \mathbb{R} satisfying, for all x, y, z \in X:

(i) d(x, y) = 0 if, and only if, x = y;
(ii) d(x, y) \leq d(z, x) + d(z, y).

From these properties, we can easily deduce that d(x, y) \geq 0 and d(y, x) = d(x, y) for all x, y \in X. The last requirement is called the triangle inequality. If d is a metric on X, we say that (X, d) is a metric space (for short, an MS).

Definition 1 (see [22]). A triple (X, d, ≤) is called a partially ordered metric space if (X, d) is a MS and ≤ is a partial order on X.

Definition 2 (see [2]). An ordered MS (X, d, ≤) is said to have the sequential g-monotone property if it verifies

(i) if \{x_m\} is a nondecreasing sequence and \{x_m\} \to x, then \lim_{m \to \infty} g(x_m) \leq g(x) for all m;
(ii) if \{y_m\} is a nonincreasing sequence and \{y_m\} \to y, then \lim_{m \to \infty} g(y_m) \geq g(y) for all m.

If g is the identity mapping, then X is said to have the sequential monotone property.

Henceforth, fix a partition \{A, B\} of two non-empty subsets of \Lambda_n = \{1, 2, \ldots, n\}; that is, A ∪ B = \Lambda_n and A ∩ B = \emptyset. We will denote

\Omega_{A,B} = \{\sigma : \Lambda_n \to \Lambda_n : \sigma(A) \subseteq A \text{ and } \sigma(B) \subseteq B\},
\Omega'_{A,B} = \{\sigma : \Lambda_n \to \Lambda_n : \sigma(A) \subseteq B \text{ and } \sigma(B) \subseteq A\}.

(1)

If (X, ≤) is a partially ordered space, x, y \in X, and i \in \Lambda_n, we will use the following notation:

x \preceq_i y \iff \begin{cases} x \leq y, & \text{if } i \in A, \\ x \geq y, & \text{if } i \in B. \end{cases}

Let F : X^n \to X and \rho : X \to X be two mappings.

Definition 3 (see [11]). One says that F and \rho are commuting if \rho \circ F(x_1, \ldots, x_n) = F(\rho(x_1), \ldots, \rho(x_n)) for all x_1, \ldots, x_n \in X.

Definition 4 (see [11]). Let (X, ≤) be a partially ordered space. One says that F has the mixed g-monotone property (with respect to \{A, B\}) if F is g-monotone nondecreasing in arguments of A and g-monotone nonincreasing in arguments of B; that is, for all x_1, x_2, \ldots, x_n, y, z \in X and all i,

\begin{align*}
gy \leq gz \quad \Rightarrow \quad F(x_1, \ldots, x_{i-1}, y, x_{i+1}, \ldots, x_n) & \leq F(x_1, \ldots, x_{i-1}, z, x_{i+1}, \ldots, x_n). \quad (3)
\end{align*}

Henceforth, let \sigma_1, \sigma_2, \ldots, \sigma_n, \tau : \Lambda_n \to \Lambda_n be n + 1 mappings from \Lambda_n into itself, and let \Phi be the (n + 1)-tuple (\sigma_1, \sigma_2, \ldots, \sigma_n, \tau).

Definition 5 (see [11]). A point (x_1, x_2, \ldots, x_n) \in X^n is called a \Phi-coincidence point of the mappings F and \rho if

\begin{align*}
F(x_{\sigma_1(1)}, x_{\sigma_2(2)}, \ldots, x_{\sigma_n(n)}) = \rho(x_{\tau(0)}) & \quad \forall i. \quad (4)
\end{align*}

If \rho is the identity mapping on X, then (x_1, x_2, \ldots, x_n) \in X^n is called a \rho-fixed point of the mapping F.

Remark 6. If F and \rho are commuting and (x_1, x_2, \ldots, x_n) \in X^n is a \rho-fixed point of F and \rho, then (gx_1, gx_2, \ldots, gx_n) also is a \rho-fixed point of F and \rho.

Definition 7 (see [14]). A partial metric on X is a mapping p : X \times X \to \mathbb{R}_0^+ verifying, for all x, y, z \in X:

\begin{align*}
(P1) & \quad p(x, x) \leq p(x, y); \\
(P2) & \quad p(x, x) = p(x, y) = p(y, y) \Rightarrow x = y; \\
(P3) & \quad p(x, y) = p(y, x); \\
(P4) & \quad p(x, z) + p(y, y) \leq p(x, y) + p(y, z).
\end{align*}

In this case, (X, p) is a partial metric space (for short, a PMS).

Example 8 (see, e.g., [14]). Let X = \mathbb{R}_0^+, and define p on X by

\begin{align*}
p(x, y) = \max\{x, y\} & \quad \forall x, y \in X. \quad (5)
\end{align*}

Then, (X, p) is a partial metric space.

Example 9 (see [14]). Let X = \{[a, b] : a, b \in \mathbb{R}, a \leq b\}, and define p([a, b], [c, d]) = \max\{|b, d| - \min\{a, c\}. Then, (X, p) is a partial metric space.

Example 10 (see [14]). Let X = [0, 1] ∪ [2, 3], and define p : X \times X \to \mathbb{R}_0^+ by

\begin{align*}
p(x, y) = \begin{cases} & \max\{x, y\}, \quad \text{if } \{x, y\} \cap [2, 3] \neq \emptyset, \\ & |x - y|, \quad \text{if } \{x, y\} \subset [0, 1]. \end{cases}
\end{align*}

Then, (X, p) is a partial metric space.

Example 11 (see, e.g., [23, 24]). Let (X, d) and (X, p) be a metric space and a partial metric space, respectively. Functions \rho_i : X \times X \to \mathbb{R}_0^+ (i \in \{1, 2, 3\}) given by

\begin{align*}
\rho_1(x, y) = d(x, y) + p(x, y), \\
\rho_2(x, y) = d(x, y) + \max\{u(x), u(y)\}, \\
\rho_3(x, y) = d(x, y) + a,
\end{align*}

define partial metrics on X, where u : X \to \mathbb{R}_0^+ is an arbitrary function and a \geq 0.

Obviously, if (X, d) is a MS and we define p = d, then (X, p) is a PMS. Indeed, a partial metric p on X verifies

\begin{align*}
(i) & \quad p(x, y) = 0 \Rightarrow x = y; \\
(ii) & \quad p(x, y) = p(y, x); \\
(iii) & \quad p(x, z) \leq p(x, y) + p(y, z),
\end{align*}
but the condition $p(x, x) = 0$ does not necessarily hold. For a partial metric $p$ on $X$, the mappings $d_p, d_m : X \times X \rightarrow \mathbb{R}_0^+$ given by
\[
d_p(x, y) = 2p(x, y) - p(x, x) - p(y, y),
d_m(x, y) = \max\{p(x, y) - p(x, x), p(y, y) - p(y, y)\} = p(x, y) - \min\{p(x, x), p(y, y)\},
\]
(7)
for all $x, y \in X$, are (usual) metrics on $X$. On a PMS, the concepts of convergence, Cauchy sequences, completeness, and continuity are defined as follows.

**Definition 12** (see [14, 25, 26]). Let $\{x_m\}$ be a sequence on a PMS $(X, p)$.

(i) $\{x_m\}$ $p$-converges to $x \in X$ (and one will write $\{x_m\} \xrightarrow{p} x$) if $p(x, x) = \lim_{m \to \infty} p(x, x_m)$.

(ii) $\{x_m\}$ is called $p$-Cauchy if $\lim_{m, m' \to \infty} p(x_m, x_{m'})$ exists (and it is finite).

(iii) $(X, p)$ is said to be $p$-complete if every $p$-Cauchy sequence $\{x_m\}$ in $X$ $p$-converges to a point $x \in X$ such that $p(x, x) = \lim_{m, m' \to \infty} p(x_m, x_{m'})$.

(iv) A mapping $f : X \rightarrow X$ is said to be $p$-continuous at $x_0 \in X$ if, for every $\varepsilon > 0$, there exists $\delta > 0$ such that $f(B_p(x_0, \delta)) \subseteq B_p(f(x_0), \varepsilon)$.

We have used the previous notation because we need to distinguish between $p$-convergence and $d_p$-convergence on $X$ and usual convergence for real sequences.

**Lemma 13** (see [14, 25, 26]). Let $\{x_m\}$ be a sequence on a PMS $(X, p)$.

1. $\{x_m\}$ is $p$-Cauchy if, and only if, it is $d_p$-Cauchy.

2. $\{x_m\} \xrightarrow{d_p} x$ if, and only if, $\{x_m\} \xrightarrow{p} x$ and $p(x, x) = \lim_{m, m' \to \infty} p(x_m, x_{m'})$; that is,
\[
\{d_p(x_m, x)\} \xrightarrow{0} 0 \iff \lim_{m \to \infty} p(x_m, x_{m'}) = p(x, x).
\]

3. $(X, p)$ is complete if, and only if, the MS $(X, d_p)$ is complete.

4. If $\{x_m\} \xrightarrow{p} x$ and $p(x, x) = 0$, then $\lim_{m \to \infty} p(x_m, y) = p(x, y)$ for all $y \in X$.

3. Auxiliary Results

We will use the following results about real sequences in the proof of our main theorems.

**Lemma 14.** Let $\{a_m^1, a_m^2, \ldots, a_m^n\}$ be $n$ real lower bounded sequences such that $\{\max(a_m^1, a_m^2, \ldots, a_m^n)\}_{m \in \mathbb{N}} \rightarrow \delta$. Then, there exists $i_0 \in \{1, 2, \ldots, n\}$ and a subsequence $\{a_m^{i_0}\}_{k \in \mathbb{N}}$ such that $\{a_m^{i_0}\}_{k \in \mathbb{N}} \rightarrow \delta$.

**Proof.** Let $b_m = \max(a_m^1, a_m^2, \ldots, a_m^n)$ for all $m$. As $\{b_m\}$ is convergent, it is bounded. As $a_m^i \leq a_m^n$ for all $m$ and $i$, then every $\{a_m^i\}$ is bounded. As $\{a_m^i\}_{m \in \mathbb{N}}$ is a real bounded sequence, it has a convergent subsequence $\{a_{\sigma(m)}^i\}_{m \in \mathbb{N}} \rightarrow a_i$. Consider the subsequences $\{a_{\sigma(m)}^2\}_{m \in \mathbb{N}}, \{a_{\sigma(m)}^3\}_{m \in \mathbb{N}}, \ldots, \{a_{\sigma(m)}^n\}_{m \in \mathbb{N}}$; that are $n - 1$ real bounded sequences and the sequence $\{b_{\sigma(m)}\}_{m \in \mathbb{N}}$ that also converges to $\delta$. As $\{a_{\sigma(m)}\}_{m \in \mathbb{N}}$ is a real bounded sequence, it has a convergent subsequence $\{a_{\sigma, \sigma(m)}^1\}_{m \in \mathbb{N}} \rightarrow a_1$. Then, the sequences $\{a_{\sigma, \sigma(m)}^2\}_{m \in \mathbb{N}}, \{a_{\sigma, \sigma(m)}^3\}_{m \in \mathbb{N}}, \ldots, \{a_{\sigma, \sigma(m)}^n\}_{m \in \mathbb{N}}$ also are $n - 2$ real bounded sequences, $\{a_{\sigma, \sigma(m)}^1\}_{m \in \mathbb{N}} \rightarrow a_1$, and $\{b_{\sigma, \sigma(m)}\}_{m \in \mathbb{N}} \rightarrow \delta$. Repeating this process $n$ times, we can find $n$ subsequences $\{a_{\sigma_1(m)}\}_{m \in \mathbb{N}}, \{a_{\sigma_2(m)}\}_{m \in \mathbb{N}}, \ldots, \{a_{\sigma_n(m)}\}_{m \in \mathbb{N}}$ (where $\sigma = \sigma_n \cdots \sigma_1$) such that $\{a_{\sigma_i(m)}\}_{m \in \mathbb{N}} \rightarrow a_i$ for all $i$. And $\{b_{\sigma(m)}\}_{m \in \mathbb{N}} \rightarrow \delta$. But
\[
\{b_{\sigma(m)}\}_{m \in \mathbb{N}} = \left\{ \max(a_{\sigma_1(m)}, a_{\sigma_2(m)}, \ldots, a_{\sigma_n(m)}) \right\}_{m \in \mathbb{N}} \rightarrow \max(a_1, a_2, \ldots, a_n),
\]

Proof. Suppose that the conclusion is not true. Then, there exists $\varepsilon_0 > 0$ such that, for all $\delta \in [0, \varepsilon_0]$, there exists $m_0 \in \mathbb{N}$ verifying $a_{m_0} < \delta$. Let $k_0 \in \mathbb{N}$ be such that $|k_0 - k| < \varepsilon_0$. For all $k \in \mathbb{N}$, take $\delta_k = 1/(k + k_0^2) \in [0, \varepsilon_0]$. Then, there exists $m(k) \in \mathbb{N}$ verifying $0 \leq a_{m(k)} < \delta_k = 1/(k + k_0^2)$. Taking limit when $k \to \infty$, we deduce that $\lim_{k \to \infty} a_{m(k)} = 0$. Then, $\{a_m\}$ has a subsequence converging to zero (maybe, reordering $\{a_{m(k)}\}$), but this is a contradiction.

**Lemma 15.** Let $\{a_m\}_{m \in \mathbb{N}}$ be a sequence of nonnegative real numbers which has not any subsequence converging to zero. Then, for all $\varepsilon > 0$, there exist $\delta \in [0, \varepsilon]$ and $m_0 \in \mathbb{N}$ such that $a_m \geq \delta$ for all $m \geq m_0$.

Proof. Suppose that the conclusion is not true. Then, there exists $\varepsilon_0 > 0$ such that, for all $\delta \in [0, \varepsilon_0]$, there exists $m_0 \in \mathbb{N}$ verifying $a_{m_0} < \delta$. Let $k_0 \in \mathbb{N}$ be such that $|k_0 - k| < \varepsilon_0$. For all $k \in \mathbb{N}$, take $\delta_k = 1/(k + k_0^2) \in [0, \varepsilon_0]$. Then, there exists $m(k) \in \mathbb{N}$ verifying $0 \leq a_{m(k)} < \delta_k = 1/(k + k_0^2)$. Taking limit when $k \to \infty$, we deduce that $\lim_{k \to \infty} a_{m(k)} = 0$. Then, $\{a_m\}$ has a subsequence converging to zero (maybe, reordering $\{a_{m(k)}\}$), but this is a contradiction.

**Lemma 16.** If $\{x_m\}_{m \in \mathbb{N}}$ is a sequence in a MS $(X, d)$ that is not Cauchy, then there exist $\varepsilon_0 > 0$ and two subsequences $\{x_{m(k)}\}_{k \in \mathbb{N}}$ and $\{x_{n(k)}\}_{k \in \mathbb{N}}$ such that, for all $k \in \mathbb{N}$,
\[
k < m(k) < n(k) < (k + 1), \quad d(x_{m(k)}, x_{n(k)}) \geq \varepsilon_0, \quad d(x_{m(k)}, x_{n(k) - 1}) < \varepsilon_0.
\]

Proof. We know that
\[
\{x_m\} \text{ is Cauchy} \quad \iff \quad \forall \varepsilon > 0, \exists n_0 \in \mathbb{N} : (m, n \geq n_0 \Rightarrow d(x_m, x_n) < \varepsilon).
\]
If this condition is not true, then
\[
\exists \varepsilon_0 > 0 : (\forall n_0 \in \mathbb{N}, \exists m, n \geq n_0 \text{ such that } d(x_m, x_n) \geq \varepsilon_0).
\]
Let $n_0 = 2$. Then, there exists $m_1, n_1 \in \mathbb{N}$ such that $m_1, n_1 \geq n_0$ and $d(x_{m_1}, x_{n_1}) \geq \varepsilon_0$. Let $m(1) = \min(m_1, n_1) \geq n_0 = 2 > 1$, and consider the numbers

\[
d(x_{m(1)}, x_{m(1)+1}),
\]

\[
d(x_{m(1)}, x_{m(1)+2}), \ldots, d(x_{m(1)}, x_{\max(m_1, n_1)}).
\]

Since $d(x_{m(1)}, x_{\max(m_1, n_1)}) = d(x_{m_1}, x_{n_1}) \geq \varepsilon_0$, between the previous numbers there exists a first nonnegative integer $n(1) \in \{m(1) + 1, m(1) + 2, \ldots, \max(m_1, n_1) \}$ such that $d(x_{m(1)}, x_{n(1)}) \geq \varepsilon_0$ but $d(x_{m(1)}, x_j) < \varepsilon_0$ for all $j \in \{m(1), m(1)+1, \ldots, n(1)-1\}$. In particular, $d(x_{m(1)}, x_{n(1)-1}) < \varepsilon_0$.

Now, let $n_0 = n(1) + 1$. Then, there exists $m_2, n_2 \in \mathbb{N}$ such that $m_2, n_2 \geq n(1) + 1$ and $d(x_{m_2}, x_{n_2}) \geq \varepsilon_0$. Let $m(2) = \min(m_2, n_2) \geq n(1) + 1 > n(1)$, and consider the numbers

\[
d(x_{m(2)}, x_{m(2)+1}),
\]

\[
d(x_{m(2)}, x_{m(2)+2}), \ldots, d(x_{m(2)}, x_{\max(m_2, n_2)}).
\]

Since $d(x_{m(2)}, x_{\max(m_2, n_2)}) = d(x_{m_2}, x_{n_2}) \geq \varepsilon_0$, between the previous numbers there exists a first nonnegative integer $n(2) \in \{m(2) + 1, m(2) + 2, \ldots, \max(m_2, n_2) \}$ such that $d(x_{m(2)}, x_{n(2)}) \geq \varepsilon_0$ but $d(x_{m(2)}, x_j) < \varepsilon_0$ for all $j \in \{m(2), m(2)+1, \ldots, n(2)-1\}$. In particular, $d(x_{m(2)}, x_{n(2)-1}) < \varepsilon_0$.

Repeating this process, we can find two subsequences \{\{x_{m_k}\}\} and \{\{x_{n_k}\}\} such that, for all $k \in \mathbb{N}$:

\[
k < m(k) < n(k) < m(k + 1),
\]

\[
d(x_{m(k)}, x_{n(k)}) \geq \varepsilon_0, \quad d(x_{m(k)}, x_{n(k)-1}) < \varepsilon_0.
\]

Definition 17. Let $\Psi$ be the family of all continuous, nondecreasing mappings $\psi : \mathbb{R}_0^+ \rightarrow \mathbb{R}_0^+$ such that $\psi(t) = 0$ if, and only if, $t = 0$.

These mappings are known as altering distance functions (see [27]). Note that every selected $\psi \in \Psi$ commutes with $\max$; that is, $\psi(\max(s_1, s_2, \ldots, s_N)) = \max(\psi(s_1), \psi(s_2), \ldots, \psi(s_N))$ for all $s_1, s_2, \ldots, s_N \in [0, \infty)$.

Lemma 18. If $\psi \in \Psi$ and $\lim_{m \rightarrow \infty} \psi(a_m) = 0$, then $\lim_{m \rightarrow \infty} a_m = 0$.

Proof. As there exists $\psi(a_m)$, then $a_m \in \text{dom} \psi = [0, \infty)$. If the conclusion is not true, there exists $\varepsilon_0 > 0$ such that, for all $n_0 \in \mathbb{N}$, there exists $n \geq n_0$ verifying $a_n \geq \varepsilon_0$. This means that $\{a_m\}$ has a subsequence $\{a_{m(k)}\}_k$ such that $a_{m(k)} \geq \varepsilon_0$. As $\psi$ is nondecreasing, $\psi(\varepsilon_0) \leq \psi(a_{m(k)})$ for all $k \in \mathbb{N}$. Therefore, $\{\psi(a_{m(k)})\}_k$ has a subsequence $\{\psi(a_{m(k)})\}_k$ lower bounded by $\psi(\varepsilon_0) > 0$, but this is impossible since $\lim_{m \rightarrow \infty} \psi(a_m) = 0$.

With regards to coincidence points, it is possible to consider the following simplification. If $\tau$ is a permutation of $\Lambda_n$, and we reorder (4), then we deduce that every coincidence point may be seen as a coincidence point associated to the identity mapping on $\Lambda_n$ (see, for instance, [28]).

Lemma 19. Let $\tau$ be a permutation of $\Lambda_n$, and let $\Phi = (\sigma_1, \sigma_2, \ldots, \sigma_n, \tau)$ and $\Phi' = (\sigma_{\tau^{-1}(1)}, \sigma_{\tau^{-1}(2)}, \ldots, \sigma_{\tau^{-1}(n)}, I_{\Lambda_n})$. Then, a point $(x_1, x_2, \ldots, x_n) \in X^n$ is a $\Phi'$-coincidence point of the mappings $F$ and $g$ if, and only if, $(x_1, x_2, \ldots, x_n)$ is a $\Phi'$-coincidence point of the mappings $F$ and $g$.

Therefore, in the sequel, without loss of generality, we will only consider $Y$-coincidence points where $Y = (\sigma_1, \sigma_2, \ldots, \sigma_n)$, that is, that verify $F(x_{\sigma(1)}, x_{\sigma(2)}, \ldots, x_{\sigma(n)}) = gx_i$ for all $i$. We also show some preliminary results on PMS.

Lemma 20. Let \{\{x_m\}\} be a sequence on a PMS $(X, p)$, and let $x \in X$.

(1) If $\{x_m\} \xrightarrow{p} x$ and $p(x, x) = 0$, then $\{x_m\} \xrightarrow{d_p} x$, $\{d_p(x_m, x)\} \rightarrow d_p(x, x)$, and $\{p(x_m, y)\} \rightarrow p(x, y)$ for all $y \in X$.

(2) If $\{x_m\} \xrightarrow{d_p} x$ and $\{p(x_m, x_m)\} \rightarrow 0$, then $p(x, x) = 0$.

Proof. (1) Since $0 \leq p(x_m, x_m) \leq p(x, x)$ and $\lim_{m \rightarrow \infty} p(x_m, x_m) = p(x, x) = 0$, then $\lim_{m \rightarrow \infty} d_p(x_m, x_m) = \lim_{m \rightarrow \infty} (2p(x_m, x) - p(x, x) - p(x_m, x_m)) = 0$, so $\{x_m\} \xrightarrow{d_p} x$. Since $d_p$ is continuous, then $\{d_p(x_m, y)\} \rightarrow d_p(x, y)$ for all $y \in X$, and item 4 of Lemma 13 implies that $\{p(x_m, y)\} \rightarrow p(x, y)$.

(2) Item 2 of Lemma 13 shows that $p(x, x) = \lim_{m \rightarrow \infty} p(x_m, x_m) = \lim_{m \rightarrow \infty} (2p(x_m, x) - p(x, x) - p(x_m, x_m)) = 0$.

Remark 21. Although the limit in a MS is unique, the $p$-limit in a PMS is not necessarily unique. For instance, let $(X, p)$ as in Example 10. Then, $(X, p)$ is a complete PMS (see [14]).

Consider $\{x_m\} = 2.5 - 1/(2m)$ for all $m \in \mathbb{N}$. Then, $\{x_m\} \xrightarrow{d} 2.5$ but $\{x_m\} \xrightarrow{p} x_0$ whenever $x_0 \in [2.5, 3]$.

Definition 22. Let $N \in \mathbb{N}$, let $(X, p)$ be a PMS, let $G : X^N \rightarrow X$ be a mapping, and let $Y_0 = (x_1, x_2, \ldots, x_N) \in X^N$. We will say that $G$ is $a_p$-continuous at $Y_0$ if, for all sequences $\{x'_1, x'_2, \ldots, x'_N\}$ on $X$ such that $x'_i \xrightarrow{p} x_i$ for all $i \in \{1, 2, \ldots, N\}$, $p(x_i, x'_i) = 0$ for all $i \in \{1, 2, \ldots, N\}$ and $p(G(x'_1, x'_2, \ldots, x'_N), G(x_1, x_2, \ldots, x_N)) = 0$, we have that $G(x'_1, x'_2, \ldots, x'_N) \xrightarrow{p} G(Y_0)$ and $p(G(Y_0), G(Y_0)) = 0$. One will say that $G$ is $a_p$-continuous if it is continuous at every point $Y_0 \in X^N$.

Lemma 23. If $(X, p)$ is a PMS, and $G : X^N \rightarrow X$ is $d_p$-continuous at $Y_0 \in X^N$, then $G$ is $a_p$-continuous at $Y_0$.

Proof. Let $\{x'_1, x'_2, \ldots, x'_N\}$ sequences on $X$ such that $x'_i \xrightarrow{p} x_i$ for all $i \in \{1, 2, \ldots, N\}$, $p(x_i, x'_i) = 0$ for all $i \in \{1, 2, \ldots, N\}$, and $p(G(x'_1, x'_2, \ldots, x'_N), G(x_1, x_2, \ldots, x_N)) = 0$. Item 1
of Lemma 20 implies that \( \{x^i_m\} \stackrel{d}{\rightarrow} x_i \) for all \( i \in \{1, 2, \ldots, N\} \). Since \( G \) is \( d_p \)-continuous at \( Y_0 = (x_1, x_2, \ldots, x_N) \), then

\[
\{G(x^i_m, x^j_m, \ldots, x^K_m)\} \stackrel{d}{\rightarrow} G(x_1, x_2, \ldots, x_N). \]

Item 2 of Lemma 13 assures us that \( \{G(x^i_m, \ldots, x^N_m)\} \overset{p}{\rightarrow} G(x_1, \ldots, x_N) \) and

\[
p(G(x_1, x_2, \ldots, x_N), G(x_1, x_2, \ldots, x_N)) = \lim_{m, m' \to \infty} p(G(x^i_m, x^j_m, \ldots, x^K_m), G(x^i_m, x^j_m, \ldots, x^K_m)) = \lim_{m \to \infty} p(G(x^i_m, x^j_m, \ldots, x^K_m), G(x^i_m, x^j_m, \ldots, x^K_m)) = 0.
\]

(16)

Then, \( G \) is \( \alpha_p \)-continuous at \( Y_0 \).

\[\Box\]

### 4. Main Results

In the following result, we show sufficient conditions to ensure the existence of \( Y \)-coincidence points, where \( Y = (\sigma_1, \sigma_2, \ldots, \sigma_n) \).

**Theorem 24.** Let \((X, p)\) be a complete PMS, and let \( \leq \) be a partial order on \( X \). Let \( Y = (\sigma_1, \sigma_2, \ldots, \sigma_n) \) be an \( n \)-tuple of mappings from \( \{1, 2, \ldots, n\} \) into itself verifying \( \sigma_i \in \Omega_{AB} \) if \( i \in A \) and \( \sigma_i \in \Omega_{AA} \) if \( i \in B \). Let \( F : X^n \to X \) and \( \alpha : X \rightarrow X \) be two mappings such that \( F \) has the mixed-g-monotone property on \( X, \mathcal{F}(X^n) \subseteq \mathcal{g}(X) \) and \( \alpha \) is \( \alpha_p \)-continuous and commuting with \( F \). Assume that there exist \( \psi, \varphi \in \Psi \) such that

\[
\psi(p(F(x_1, x_2, \ldots, x_n), F(y_1, y_2, \ldots, y_n))) \leq \psi\left(\max_{1 \leq i \leq n} g(x_i, y_i)\right) - \varphi\left(\max_{1 \leq i \leq n} g(x_i, y_i)\right),
\]

(17)

for which \( g_{x_i} \leq g_{y_i} \) for all \( i \). Suppose either \( F \) is \( \alpha_p \)-continuous or \((X, d_p, \leq)\) has the sequential g-monotone property. If there exist \( x^i_0, x^j_0, \ldots, x^K_0 \) \( \in X \) verifying \( g_{x^i_0} \leq F(x^0_{i(1)}, x^0_{i(2)}, \ldots, x^0_{i(n)}) \) for all \( i \), then \( F \) and \( \alpha \) have, at least, one \( Y \)-coincidence point.

**Proof.** The proof is divided into seven steps. The first two steps are the same as in the proof of Theorem 9 in [11], since the contractivity condition does not play any role in these parts of the proof.

**Step 1.** There exist \( n \) sequences \( \{x^i_m\}_{m \geq 0}, \{x^2_m\}_{m \geq 0}, \ldots, \{x^K_m\}_{m \geq 0} \) such that \( g_{x^i_{m + 1}} = F(x^0_{i(1)}, x^0_{i(2)}, \ldots, x^0_{i(n)}) \) for all \( m \) and all \( i \).

**Step 2.** \( g_{x^i_m} \leq g_{x^j_m} \) for all \( m \) and all \( i \).

**Step 3.** We claim that \( \{p(g_{x^i_m}, g_{x^j_m})\}_{m \geq 0} \to 0 \) for all \( i \) (i.e., \( \max_{1 \leq j \leq n} p(g_{x^j_m}, g_{x^j_{m + 1}}) \to 0 \)).

Indeed, define \( \delta_m = \max_{1 \leq j \leq n} p(g_{x^j_m}, g_{x^j_{m + 1}}) \) for all \( m \). As \( g_{x^i_m} \leq g_{x^i_{m + 1}} \) for all \( m \) and all \( i \), then condition (17) implies that, for \( m \geq 1 \) and all \( i \):

\[
\psi(p(g_{x^i_m}, g_{x^j_m})) = \psi(p(F(x^i_{m(1)}, x^j_{m(1)}), \ldots, x^i_{m(n)}, x^j_{m(n)})) \leq \psi(\max_{1 \leq i \leq n} p(g_{x^i_{m(1)}}, g_{x^j_{m(1)}})) - \varphi(\max_{1 \leq j \leq n} p(g_{x^i_{m(j)}}, g_{x^j_{m(j)}})) \leq \psi(p(g_{x^i_m}, g_{x^j_m})) = \delta_m.
\]

(18)

Therefore, for all \( m \geq 1, \delta_m = \max_{1 \leq l \leq n} p(g_{x^l_m}, g_{x^l_{m + 1}}) \) is nonincreasing and lower bounded. Hence, it is convergent; that is, there exists \( \Delta \geq 0 \) such that \( \psi(\delta_m) \to \Delta \). We are going to show that \( \Delta = 0 \).

\[
\psi(\max_{1 \leq l \leq n} p(g_{x^l_m}, g_{x^l_{m + 1}})) = \psi(\max_{1 \leq l \leq n} \psi(p(g_{x^l_m}, g_{x^l_{m + 1}}))) \leq \psi(\delta_m), \quad \Delta \to 0.
\]

(19)

Lemma 14 assures that there exist \( \delta_0 \in \{1, 2, \ldots, n\} \) and a subsequence \( \{p(g_{x^i_{m_k}}, g_{x^i_{m_{k + 1}}})\}_{k \geq 1} \) such that \( \psi(p(g_{x^i_{m_k}}, g_{x^i_{m_{k + 1}}})) \to \Delta \). Repeating (18), for all \( k \geq 1, \)

\[
\psi(p(g_{x^j_{m_k}}, g_{x^j_{m_{k + 1}}})) \leq \psi(\max_{1 \leq j \leq n} p(g_{x^j_{m_k}}, g_{x^j_{m_{k + 1}}})) = \psi(\delta_{m_k}) \to \Delta.
\]

(20)

Consider the sequence

\[
\max_{1 \leq j \leq n} p(g_{x^j_{m_{k + 1}}}, g_{x^j_{m_k}}) \to \Delta \quad \text{if} \quad \Delta \geq 0.
\]

(21)

Suppose that this sequence has no subsequence converging to zero. Using \( \varepsilon = 1 \), Lemma 15 assures us that there exists \( \delta^\prime \in [0, 1] \) and \( k_0 \in \mathbb{N} \) such that \( \max_{1 \leq j \leq n} p(g_{x^j_{m_k}}, g_{x^j_{m_{k + 1}}}) \geq \delta^\prime \) for all \( k \geq k_0 \). It follows that

\[
-\varphi(\max_{1 \leq j \leq n} p(g_{x^j_{m_{k + 1}}}, g_{x^j_{m_k}})) \leq -\varphi(\delta^\prime) \quad \forall k \geq k_0.
\]

(22)
Then, (20) says to us

$$\psi\left(p\left(g_{x_{m(k)}}(j), g_{x_{n(k)+1}}(j)\right)\right)$$

$$\leq \psi\left(\max_{1 \leq j \leq n}\left(g_{x_{m(k)-1}}^{a(j)} g_{x_{n(k)}}^{a(j)}\right)\right)$$

$$- \varphi\left(\max_{1 \leq j \leq n}\left(g_{x_{m(k)-1}}^{a(j)} g_{x_{n(k)}}^{a(j)}\right)\right)$$

$$\leq \psi\left(\max_{1 \leq j \leq n}\left(g_{x_{m(k)-1}}^{a(j)} g_{x_{n(k)}}^{a(j)}\right)\right) - \varphi\left(\delta'\right)$$

$$\leq \psi\left(\delta_{m(k)-1}\right) - \varphi\left(\delta'\right).$$

Taking limit in $k$, we deduce that $\Delta \leq \Delta - \varphi(\delta') < \Delta$, which is impossible. Therefore, the sequence in (21) must have a subsequence $\{\max_{1 \leq j \leq n}\left(p(g_{x_{m(k)-1}}^{a(j)} g_{x_{n(k)}}^{a(j)})\right)\}_{k \geq 1}$ converging to zero. Since $\psi$ and $\varphi$ are continuous, taking limit when $k \to \infty$ in (20) using this subsequence, we deduce that $0 \leq \Delta \leq \psi(0) - \varphi(0) = 0$, so $\Delta = 0$. Then, we have just proved that $\Delta = 0$. Therefore, $p(\delta_{m(k)})_{m \geq 1} \to 0$, and Lemma 18 assures that $\{\delta_{m(k)}\}_{m \geq 1} \to 0$, which means that $p(g_{x_{m(k)}, g_{x_{n(k)}}}) \to 0$ for all $j$ since $0 \leq p(g_{x_{m(k)}, g_{x_{n(k)}}}) \leq \delta_{m}$ for all $m$ and all $j$.

Step 4. $\{p(g_{x_{m(k)}, g_{x_{n(k)}}})\}_{m \geq 0} \to 0$ for all $i$ (i.e., $\max_{1 \leq j \leq n}\left(p(g_{x_{m(k)-1}}^{a(j)} g_{x_{n(k)}}^{a(j)})\right)_{m \geq 0} \to 0$). It is the same proof of Step 3.

Since $d_{p}(g_{x_{m(k)}, g_{x_{n(k)}}}) = 2p(g_{x_{m(k)}, g_{x_{n(k)}}}) - p(g_{x_{m(k)-1}, g_{x_{n(k)}}}) - p(g_{x_{m(k)+1}, g_{x_{n(k)}}})$ for all $m$ and $i$, joining Steps 3 and 4, it follows that

$$d_{p}(g_{x_{m(k)}, g_{x_{n(k)}}}) \to 0 \quad \forall i.$$  (24)

Step 5. Every sequence $\{g_{x_{m(k)}}\}_{m \geq 0}$ is $d_{p}$-Cauchy. We reason by contradiction. Suppose that $\{g_{x_{m(k)}}\}_{m \geq 0}$ and $\{g_{x_{n(k)}}\}_{m \geq 0}$ are not $d_{p}$-Cauchy ($s \geq 1$) and $\{g_{x_{m(k)}}\}_{m \geq 0}$ and $\{g_{x_{n(k)}}\}_{m \geq 0}$ are $d_{p}$-Cauchy, being $\{l_{1}, \ldots, l_{n}\} = \{1, \ldots, n\}$. By Lemma 16, for all $r \in \{1, 2, \ldots, s\}$, there exists $\epsilon_{r} > 0$ and subsequences $\{g_{x_{m(k)}}\}_{k \in \mathbb{N}}$ and $\{g_{x_{n(k)}}\}_{k \in \mathbb{N}}$ such that

$$k < m_{k}(k) < n_{k}(k),$$

$$d_{p}(g_{x_{m(k)}}, g_{x_{n(k)}}) \geq \epsilon_{r},$$

$$d_{p}(g_{x_{m(k)}}, g_{x_{n(k)+1}}) < \epsilon_{r}, \quad \forall k \in \mathbb{N}.$$  (25)

Now, let $\epsilon_{0} = \max(\epsilon_{1}, \ldots, \epsilon_{s}) > 0$ and $\epsilon'_{0} = \min(\epsilon_{1}, \ldots, \epsilon_{s}) > 0$. Since $\{g_{x_{m(k)}}\}_{m \geq 0}$ and $\{g_{x_{n(k)}}\}_{m \geq 0}$ are $d_{p}$-Cauchy, for all $j \in \{i_{1}, \ldots, i_{s}\}$, there exists $n'_{j} \in \mathbb{N}$ such that if $m, m' \geq n'_{j}$, then $d_{p}(g_{x_{m}}, g_{x_{m'}}) < \epsilon'_{0}/8$. Since $\{p(g_{x_{m}}, g_{x_{n(k)}})\} \to 0$ by Step 4,

there exists $n'_{j} \in \mathbb{N}$ such that if $m \geq n'_{j}$, then $p(g_{x_{m}}, g_{x_{n(k)}}) < \epsilon'_{0}/8$. Define $n_{0} = \max_{j \in \{i_{1}, \ldots, i_{s}\}}(n'_{j}, n'_{j})$. If $m, m' \geq n_{0}$, then

$$0 \leq p(g_{x_{m}}, g_{x_{n(k)}}) = \frac{d_{p}(g_{x_{m}}, g_{x_{n(k)}}) + p(g_{x_{m}}, g_{x_{n(k)}}) + p(g_{x_{m}}, g_{x_{n(k)}})}{2}< \frac{\epsilon'_{0}/8 + \epsilon'_{0}/8 + \epsilon'_{0}/8}{2} = \frac{3\epsilon'_{0}}{16} < \frac{\epsilon'_{0}}{4}. \quad (26)$$

Therefore, we have proved that there exists $n_{0} \in \mathbb{N}$ such that if $m, m' \geq n_{0}$, then

$$d_{p}(g_{x_{m}}, g_{x_{n(k)}}) < \frac{\epsilon'_{0}}{4}, \quad p(g_{x_{m}}, g_{x_{n(k)}}) < \frac{\epsilon'_{0}}{4} \quad \forall j \in \{i_{1}, \ldots, i_{s}\}. \quad (27)$$

Next, let $q \in \{1, 2, \ldots, s\}$ such that $\epsilon_{q} = \epsilon'_{0} = \max(\epsilon_{1}, \ldots, \epsilon_{s})$. Let $k_{1} \in \mathbb{N}$ such that $n_{0} < m_{k_{1}}(k_{1})$, and define $m(1) = m_{k_{1}}(k_{1})$. Consider the numbers $m(1) + 1, m(1) + 2, \ldots, n_{q}(k_{1})$ until finding the first positive integer $n(1) > m(1)$ verifying

$$\max_{1 \leq r \leq s} d_{p}(g_{x_{m(r)}}^{i_{j}}, g_{x_{n(r-1)}}^{i_{j}}) \geq \epsilon_{0}, \quad d_{p}(g_{x_{m(r)}}^{i_{j}}, g_{x_{n(r)}}^{i_{j}}) < \epsilon_{0}, \quad \forall j \in \{1, 2, \ldots, s\}. \quad (28)$$

Now let $k_{2} \in \mathbb{N}$ such that $n(1) < m_{k_{2}}(k_{2})$, and define $m(2) = m_{k_{2}}(k_{2})$. Consider the numbers $m(2) + 1, m(2) + 2, \ldots, n_{q}(k_{2})$ until finding the first positive integer $n(2) > m(2)$ verifying

$$\max_{1 \leq r \leq s} d_{p}(g_{x_{m(r)}}^{i_{j}}, g_{x_{n(r-1)}}^{i_{j}}) \geq \epsilon_{0}, \quad d_{p}(g_{x_{m(r)}}^{i_{j}}, g_{x_{n(r)}}^{i_{j}}) < \epsilon_{0}, \quad \forall j \in \{1, 2, \ldots, s\}. \quad (29)$$

Repeating this process, we can find sequences such that, for all $k \geq 1$,

$$n_{0} < m(k) < n(k) < m(k + 1),$$

$$\max_{1 \leq r \leq s} d_{p}(g_{x_{m(r)}}^{i_{j}}, g_{x_{n(r)}}^{i_{j}}) \geq \epsilon_{0}, \quad \forall j \in \{1, 2, \ldots, s\}. \quad (30)$$

Note that by (27), $d_{p}(g_{x_{m(r)}}^{i_{j}}, g_{x_{n(r)}}^{i_{j}}), d_{p}(g_{x_{m(r)}}^{i_{j}}, g_{x_{n(r-1)}}^{i_{j}}) < \epsilon_{0}/4 < \epsilon_{0}/2$ for all $r \in \{s + 1, s + 2, \ldots, n\}$, so

$$\max_{1 \leq r \leq s} d_{p}(g_{x_{m(r)}}^{i_{j}}, g_{x_{n(r)}}^{i_{j}}) = \max_{1 \leq r \leq s} d_{p}(g_{x_{m(r)}}^{i_{j}}, g_{x_{n(r-1)}}^{i_{j}}) \geq \epsilon_{0}, \quad d_{p}(g_{x_{m(r)}}^{i_{j}}, g_{x_{n(r)}}^{i_{j}}) < \epsilon_{0}, \quad \forall j \in \{1, 2, \ldots, s\}. \quad (31)$$
for all \( i \in \{1, 2, \ldots, n\} \) and all \( k \geq 1 \). Furthermore, for all \( j \),
\[
2p(g_{x^j_{m(k)-1}}, g_{x^j_{m(k)-1}}) - p(g_{x^j_{m(k)-1}}, g_{x^j_{m(k)-1}}) = d_p(g_{x^j_{m(k)-1}}, g_{x^j_{m(k)-1}})
\]
\[
\leq d_p(g_{x^j_{m(k)-1}}, g_{x^j_{m(k)-1}}) + d_p(g_{x^j_{m(k)-1}}, g_{x^j_{m(k)-1}})
\]
\[
\leq d_p(g_{x^j_{m(k)-1}}, g_{x^j_{m(k)-1}}) + \varepsilon_0.
\]

Therefore, for all \( j \) and all \( k \),
\[
p(g_{x^j_{m(k)-1}}, g_{x^j_{m(k)-1}})
\]
\[
\leq (\varepsilon_0 + d_p(g_{x^j_{m(k)-1}}, g_{x^j_{m(k)-1}}) + p(g_{x^j_{m(k)-1}}, g_{x^j_{m(k)-1}})
\]
\[
\times 2^{-1}.
\]

Next, for all \( k \), let \( i(k) \in \{1, 2, \ldots, s\} \) be an index such that
\[
d_p(g_{x^{i(k)}_{m(k)}}, g_{x^{i(k)}_{m(k)}}) = \max_{1 \leq j \leq s} d_p(g_{x^{i(k)}_{m(k)}}, g_{x^{i(k)}_{m(k)}})
\]
\[
= \max_{1 \leq j \leq s} p(g_{x^{i(k)}_{m(k)}}, g_{x^{i(k)}_{m(k)}}) \geq \varepsilon_0.
\]

Then, for all \( k \),
\[
p(g_{x^{i(k)}_{m(k)}}, g_{x^{i(k)}_{m(k)}})
\]
\[
= (d_p(g_{x^{i(k)}_{m(k)}}, g_{x^{i(k)}_{m(k)}}) + p(g_{x^{i(k)}_{m(k)}}, g_{x^{i(k)}_{m(k)}})
\]
\[
\times 2^{-1} \geq \frac{\varepsilon_0}{2}.
\]

Applying the contractivity condition (17), it follows, for all \( k \),
\[
0 < \psi\left(\frac{\varepsilon_0}{2}\right)
\]
\[
\leq \psi\left(p(g_{x^{i(k)}_{m(k)}}, g_{x^{i(k)}_{m(k)}})\right)
\]
\[
\leq \psi\left(\max_{1 \leq j \leq s} p(g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}}, g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}})\right)
\]
\[
- \varphi\left(\max_{1 \leq j \leq s} p(g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}}, g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}})\right).
\]

Consider the sequence:
\[
\left\{\max_{1 \leq j \leq s} p(g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}}, g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}})\right\}_{k \geq 1}.
\]

If this sequence has a subsequence that converges to zero, then we can take limit when \( k \to \infty \) in (36) using this subsequence, so that we would have \( 0 < \psi(\varepsilon_0/2) \leq \psi(0) - \varphi(0) = 0 \), which is impossible since \( \varepsilon_0 > 0 \). Therefore, the sequence (37) has no subsequence converging to zero. In this case, taking \( \varepsilon_0 > 0 \) in Lemma 15, there exist \( \delta \in [0, \varepsilon_0[ \) and \( k_0 \in \mathbb{N} \) such that \( \max_{1 \leq j \leq s} p(g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}}, g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}}) \geq \delta \), for all \( k \geq k_0 \). It follows that, for all \( k \geq k_0 \),
\[
-\varphi(\max_{1 \leq j \leq s} p(g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}}, g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}})) \leq -\varphi(\delta).
\]

Thus, by (36),
\[
0 < \psi\left(\frac{\varepsilon_0}{2}\right)
\]
\[
\leq \psi\left(\max_{1 \leq j \leq s} p(g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}}, g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}})\right)
\]
\[
- \varphi\left(\max_{1 \leq j \leq s} p(g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}}, g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}})\right)
\]
\[
\leq \psi\left(\max_{1 \leq j \leq s} p(g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}}, g_{x^{\sigma_{i(k)}(j)}_{m(k)-1}})\right) - \varphi(\delta).
\]

Fix any \( y > 0 \) and we are going to prove that \( \psi(\varepsilon_0/2) + \varphi(\delta) \leq \psi(\varepsilon_0/2 + y) \). Indeed, by Step 3 and (24), since
\[
\left\{\max_{1 \leq j \leq s} p(g_{x^{j}_{m(k)-1}}, g_{x^{j}_{m(k)-1}})\right\},
\]
\[
\left\{\max_{1 \leq j \leq s} p(g_{x^{j}_{m(k)-1}}, g_{x^{j}_{m(k)-1}})\right\},
\]
\[
\left\{\max_{1 \leq j \leq s} p(g_{x^{j}_{m(k)-1}}, g_{x^{j}_{m(k)-1}})\right\}
\]
are sequences converging to zero, we can find \( m_1 \in \mathbb{N} \) such that if \( m(k) \geq m_1 \), then
\[
\max_{1 \leq j \leq s} p(g_{x^{j}_{m(k)-1}}, g_{x^{j}_{m(k)-1}}) \leq \frac{y}{2},
\]
\[
\max_{1 \leq j \leq s} p(g_{x^{j}_{m(k)-1}}, g_{x^{j}_{m(k)-1}}) \leq \frac{y}{2},
\]
\[
\max_{1 \leq j \leq s} p(g_{x^{j}_{m(k)-1}}, g_{x^{j}_{m(k)-1}}) \leq \frac{y}{2}.
\]

Therefore, (33) implies that, for all \( j \) and for all \( k \) such that \( m(k) > m_1 \),
\[
p(g_{x^{j}_{m(k)-1}}, g_{x^{j}_{m(k)-1}})
\]
\[
\leq \left(\varepsilon_0 + d_p(g_{x^{j}_{m(k)-1}}, g_{x^{j}_{m(k)-1}}) + p(g_{x^{j}_{m(k)-1}}, g_{x^{j}_{m(k)-1}})
\]
\[
\times 2^{-1}\right) = \frac{\varepsilon_0}{2} + \frac{3y}{4} < \frac{\varepsilon_0}{2} + y.
\]

Then, (38) guarantees that \( 0 < \psi(\varepsilon_0/2) \leq \psi(\max_{1 \leq j \leq s} p(g_{x^{j}_{m(k)-1}}, g_{x^{j}_{m(k)-1}}) - \varphi(\delta) \leq \psi(\varepsilon_0/2 + y) - \varphi(\delta) \). This means that \( \psi(\varepsilon_0/2) + \varphi(\delta) \leq \psi(\varepsilon_0/2 + y) \) for all \( y > 0 \). If we take \( y = 1/m > 0 \) (where \( m \in \mathbb{N} \)), we deduce that \( \psi(\varepsilon_0/2) + \varphi(\delta) \leq \psi(\varepsilon_0/2 + 1/m) \) for all \( m \in \mathbb{N} \). Since \( \psi \) is continuous, we have that \( \psi(\varepsilon_0/2) + \varphi(\delta) \leq \psi(\varepsilon_0/2) \), which is
impossible since \(\varphi(\delta) > 0\). This contradiction finally proves that every sequence \(\{gx^j_m\}_{m=0}^{\infty}\) is \(d_p\)-Cauchy.

Since \(X\) is \(p\)-complete, then \(X\) is \(d_p\)-complete (item 3 of Lemma 13). Then, there exist \(x_1, x_2, \ldots, x_n \in X\) such that \(\{gx^j_m\}_{d_p} \xrightarrow{} x_i\) for all \(i\). Furthermore, \(p(x_i, x_j) = \lim_{m \to \infty} p(gx_m^j, gx_m^j) = \lim_{m \to \infty} p(gx^j_m, gx^j_m) = 0\) for all \(i\). Since \(g\) is \(\alpha_p\)-continuous, therefore \(\{gx^j_m\}_{d_p} \xrightarrow{} gx_i\) and \(p(gx_i, gx_i) = 0\) for all \(i\). Item 1 of Lemma 20 shows that \(\{gx^j_m\}_{d_p} \xrightarrow{} gx_i\) for all \(i\). Therefore, for all \(i\), \(\lim_{m \to \infty} p(gx^j_{m+1}, gx^j_{m+1}) = \lim_{m \to \infty} p(gx^j_m, gx^j_m) = 0\). Moreover, for all \(m\) and all \(i\), \(gx^j_{m+1} = gF(x_m^{(1)}, x_m^{(2)}, \ldots, x_m^{(n)})\).

Step 6. Suppose that \(F\) is \(\alpha_p\)-continuous. In this case, we know that \(\{gx^j_m\}_{d_p} \xrightarrow{} x_i\) and \(p(x_i, x_j) = 0\) for all \(i\) and

\[
\begin{align*}
\{p\left(F\left(gx^j_m^{(1)}, gx^j_m^{(2)}, \ldots, gx^j_m^{(n)}\right),
F\left(gx^j_m^{(1)}, gx^j_m^{(2)}, \ldots, gx^j_m^{(n)}\right)\right) = 0, \\
\end{align*}
\]

which implies that \(\{F(gx^j_{m+1}, gx^j_{m+1})\}_{d_p} \xrightarrow{} F(x_i, x_i)\) and \(p(F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)})) = 0\) for all \(i\). Item 1 of Lemma 20 assures us that, for all \(i\),

\[
\begin{align*}
gx^j_{m+1} = \left\{F(gx^j_m^{(1)}, gx^j_m^{(2)}, \ldots, gx^j_m^{(n)})\right\}_{d_p} \xrightarrow{} F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)}).
\end{align*}
\]

Since the limit in a MS is unique, we deduce that \(F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)}) = gx_i\) for all \(i\), so \((x_1, x_2, \ldots, x_n)\) is a \(Y\)-coincidence point of \(F\) and \(g\).

Step 7. Suppose that \((X,d_p,\leq)\) has the sequential \(g\)-monotone property. In this case, by Step 2, we know that \(gx^j_m \leq gx^j_{m+1}\) for all \(m\) and all \(i\). This means that the sequence \(\{gx^j_m\}_{m=0}^{\infty}\) is monotone. As \(\{gx^j_m\}_{d_p} \xrightarrow{} x_i\), we deduce that \(\lim\{gx^j_m\}_{d_p} \leq gx_i\) for all \(m\) and all \(i\). This condition implies that, for all \(m\) and all \(j\),

\[
either \left[gx^j_m^{(i)} \leq gx_i^{(i)} \forall i\right] or \left[gx_i^{(i)} \leq gx^j_m^{(i)} \forall i\right]
\]

(the first case occurs when \(j \in A\) and the second one when \(j \in B\)). Then, by (17), for all \(j\),

\[
\psi\left(p\left(gx^j_{m+1}, F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)})\right)\right) = \psi\left(p\left(F\left(gx^j_m^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)}\right),
F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)})\right)\right)
\]

\[
\leq \psi\left(\max_{1 \leq n \leq n} p(gx^j_m^{(n)}, x_i^{(n)})\right) - \varphi\left(\max_{1 \leq n \leq n} p(gx^j_m^{(n)}, x_i^{(n)})\right) \leq \psi\left(\max_{1 \leq n \leq n} p(gx^j_m^{(n)}, x_i^{(n)})\right).
\]

Since \(\{gx^j_m\}_{d_p} \xrightarrow{} gx_i\) for all \(i\),

\[
\lim_{m \to \infty} p\left(gx^j_m^{(1)}, F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)})\right) = 0 \quad \forall i.
\]

Therefore, \(\lim_{m \to \infty} \max_{1 \leq n \leq n} p(gx^j_m^{(n)}, x_i^{(n)}) = 0\). Taking limit when \(m \to \infty\) in (45), we deduce that \(\lim_{m \to \infty} \psi(p(gx^j_m^{(n)}, F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)})) = 0\) for all \(j\). As \(\psi \in \Psi\), Lemma 18 guarantees that

\[
\lim_{m \to \infty} p\left(gx^j_m^{(1)}, F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)})\right) = 0 \quad \forall j.
\]

Finally, for all \(j\),

\[
d_p\left(gx^j_m, F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)})\right)
\]

\[
= 2p\left(gx^j_m, F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)})\right) - p\left(gx^j_m, gx^j_m\right)
\]

\[
- p\left(F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)}),
F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)})\right)
\]

\[
\leq 2p\left(gx^j_m, F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)})\right)
\]

\[
\leq 2 \left[p\left(gx^j_m, F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)})\right) p\left(gx^j_m, gx^j_m\right) + p\left(gx^j_m, F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)})\right)\right].
\]

Using (46) and (47), we conclude that \(d_p(gx^j, F(x_i^{(1)}, x_i^{(2)}, \ldots, x_i^{(n)})) = 0\) for all \(j\).

\[\square\]

\textbf{Remark 25.} In the previous theorem, if the image Im \(d\) of the metric \(d\) is not the whole set \([0, \infty]\), then \(\psi\) and \(\varphi\) can only be defined on Im \(d\), and we can consider a wider range of mappings since it is only necessary to impose that they are continuous and nondecreasing on Im \(d\).
Remark 26. We notice also that our paper cannot be deduced from the recent interesting paper of Haghdi et al. [21] on partial metric space. In fact, we use a partial order ≤. Then, we only suppose (17) for which \( g \chi_i \leq g \chi_j \) for all \( i \) (not necessarily on points which are not comparable). Further, we use a self-map \( g : X \to X \) which implies that

\[
P(A, B) = \max_{i \in [1, n]} p(g_{a_i}, g_{b_i}),
\]

\[
A = (a_1, a_2, \ldots, a_n), \quad B = (b_1, b_2, \ldots, b_n) \in X^n
\]

is not necessarily a partial metric on \( X^n \). For instance, let \( X = \mathbb{R}_0^+ = [0, \infty) \) provided with its usual partial order and the partial metric \( p(x, y) = \max(x, y) \). Consider

\[
gx = \begin{cases} 0, & \text{if } 0 \leq x \leq 1, \\ x - 1, & \text{if } x > 1. \end{cases}
\]

Then, \( g \) is continuous, but

\[
P((0, 0, \ldots, 0), (0, 0, \ldots, 0)) = P((1, 1, \ldots, 1), (0, 0, \ldots, 0)) = P((1, 1, \ldots, 1), (1, 1, \ldots, 1)) = 0,
\]

but \( (0, 0, \ldots, 0) \neq (1, 1, \ldots, 1) \). Then, \( P \) does not verify the axiom \( p(x, x) = p(x, y) = p(y, y) \Rightarrow x = y \). Therefore, we cannot apply Theorem 2.4 on Haghdi et al. [21].

As a result, we cannot use Theorem 2.7 in [21] since \( T \) has an influence in \( -\varphi(\max\{p(x, y), p(y, Ty)\}) \), and our mapping \( F \) has not a role in the left side of (17).

5. Consequences

Remark 27. Theorem 9 in [11] is an easy consequence of Theorem 24 if we take \( p = d, \varphi(t) = t \), and \( \varphi(t) = (1 - k)t \) for all \( t \in \mathbb{R}_0^+ \).

In the next result, let \( \Gamma_0 \) be the family of all nondecreasing on each argument, continuous mappings \( \varphi : [0, \infty) \to \mathbb{R}_0^+ \) verifying \( \varphi(x_1, x_2, \ldots, x_n) = 0 \) if, and only if, \( x_1 = x_2 = \cdots = x_n = 0 \). Examples of such mappings are the following, where \( k > 0, \alpha_i > 0 \) and \( n_i \in \mathbb{N} \) for all \( i \).

(i) \( \varphi(x_1, \ldots, x_n) = k \max_{1 \leq i \leq n} x_i \).

(ii) \( \varphi(x_1, \ldots, x_n) = \sum_{i=1}^{n} \alpha_i x_i^n \).

(iii) \( \varphi(x_1, \ldots, x_n) = \sqrt[n]{\alpha_1 x_1^n + \cdots + \alpha_n x_n^n} \).

Lemma 28. Let \( \varphi \in \Gamma_0 \), and define \( \varphi : \mathbb{R}_0^+ \to \mathbb{R}_0^+ \) as \( \varphi(t) = \min\{\varphi(ta_1), \varphi(ta_2), \ldots, \varphi(ta_n)\} \) for all \( t \geq 0 \), where \( \{a_1, a_2, \ldots, a_n\} \) is the usual basis of \( \mathbb{R}_0^+ \). Then, \( \varphi \in \Psi \) and \( \varphi(\max_{1 \leq i \leq n} x_i) \leq \varphi(x_1, x_2, \ldots, x_n) \) for all \( x_1, x_2, \ldots, x_n \in \mathbb{R}_0^+ \).

Proof. First part is clear. If \( x_{i_0} = \max_{1 \leq i \leq n} x_i \), then \( \varphi(x_{i_0}, a_{i_0}) = \varphi(0, 0, \ldots, 0, x_{i_0}, 0, \ldots, 0) = \varphi(x_{i_0}, x_{i_0}, \ldots, x_{i_0}, x_{i_0}, x_{i_0}, \ldots, x_{i_0}) = \varphi(x_{i_0}, x_{i_0}, \ldots, x_{i_0}) \), therefore,

\[
\varphi(\max_{1 \leq i \leq n} x_i) = \varphi(x_{i_0}) \leq \varphi(x_{i_0}, x_{i_0}) = \varphi(x_{i_0}, x_{i_0}, \ldots, x_{i_0}).
\]

Corollary 29. Thesis of Theorem 24 also holds if one replaces the contractivity condition (17) by any of the following lists (for which \( gx_i \leq g \chi_i \) for all \( i \)).

(A) This condition can be found in [11] and [12], there exist \( \psi \in \Psi \) and \( \varphi \in \Gamma_0 \) such that

\[
\psi\left( p \left( F(x_1, x_2, \ldots, x_n), F(y_1, y_2, \ldots, y_n) \right) \right) \leq \psi \left( \max_{1 \leq i \leq n} p(gx_i, gy_i) \right)
\]

(B) In [17], there exist \( \varphi \in \Psi \) and \( \beta_1, \beta_2, \ldots, \beta_n \in [0, 1] \) such that \( \beta_1 + \beta_2 + \cdots + \beta_n \leq 1 \) and

\[
\psi \left( p \left( F(x_1, x_2, \ldots, x_n), p(y_1, y_2, \ldots, y_n) \right) \right) \leq \psi \left( \sum_{i=1}^{n} \beta_i p(gx_i, gy_i) \right) - \varphi \left( \max_{1 \leq i \leq n} p(gx_i, gy_i) \right).
\]

(C) There exist \( \psi \in \Psi \) and \( \alpha_1, \alpha_2, \ldots, \alpha_n > 0 \) such that

\[
\psi \left( p \left( F(x_1, x_2, \ldots, x_n), F(y_1, y_2, \ldots, y_n) \right) \right) \leq \psi \left( \sum_{i=1}^{n} \beta_i p(gx_i, gy_i) \right) - \varphi \left( \sum_{i=1}^{n} \alpha_i p(gx_i, gy_i) \right).
\]

(D) In [2, 7, 9], there exist \( \psi \in \Psi \) and \( \alpha_1, \alpha_2, \ldots, \alpha_n > 0 \) and \( \beta_1, \beta_2, \ldots, \beta_n \geq 0 \) such that \( \beta_1 + \beta_2 + \cdots + \beta_n \leq 1 \) and

\[
\psi \left( p \left( F(x_1, x_2, \ldots, x_n), F(y_1, y_2, \ldots, y_n) \right) \right) \leq \psi \left( \sum_{i=1}^{n} \beta_i p(gx_i, gy_i) \right) - \sum_{i=1}^{n} \alpha_i p(gx_i, gy_i).
\]

(E) In [5], there exist \( \psi \in \Psi \) and \( \alpha_1, \alpha_2, \ldots, \alpha_n > 0 \) such that

\[
\psi \left( p \left( F(x_1, x_2, \ldots, x_n), F(y_1, y_2, \ldots, y_n) \right) \right) \leq \psi \left( \sum_{i=1}^{n} \beta_i p(gx_i, gy_i) \right) - \sum_{i=1}^{n} \alpha_i p(gx_i, gy_i).
\]

(F) In [19, 20], there exist \( \varphi \in \Psi \) such that \( \psi \) is subadditive (\( \psi(s + t) \leq \psi(s) + \psi(t) \) for all \( t, s \in [0, \infty) \)) and

\[
\psi \left( p \left( F(x_1, x_2, \ldots, x_n), F(y_1, y_2, \ldots, y_n) \right) \right) \leq \frac{1}{n} \left( \sum_{i=1}^{n} \psi \left( p(gx_i, gy_i) \right) - \varphi \left( \max_{1 \leq i \leq n} p(gx_i, gy_i) \right) \right).
\]

Of course, it is also interesting to particularize all the previous items to the following cases: \( \psi(t) = \lambda t \) (where \( \lambda > 0 \), \( \varphi(t) = \mu t \) (where \( \mu > 0 \)), or \( gx = x \) for all \( x \in X \).

Proof. (A) By Lemma 28, there exists \( \varphi \in \Psi \) such that \( \varphi(\max_{1 \leq i \leq n} x_i) \leq \psi(max_{1 \leq i \leq n} x_i) \) for all \( x_1, x_2, \ldots, x_n \in [0, \infty) \), so (52) implies (17). (B) It is obvious that

\[
\sum_{i=1}^{n} \beta_i p(gx_i, gy_i) \leq \left( \sum_{i=1}^{n} \beta_i \right) \max_{1 \leq i \leq n} p(gx_i, gy_i) \leq \max_{1 \leq i \leq n} p(gx_p, gy_p),
\]

so (53) implies (17). (C) We only
take \( \phi(x_1, x_2, ..., x_n) = \phi(\sum_{i=1}^{n} \alpha_i x_i) \) in item (A). (D) It is a mixture of (B) and (C). (E) It is a particular case of (D) where \( \beta_i = 1/n \) for all \( i \). (F) If \( \psi \) is subadditive, then \( (1/n)\psi(t) \leq \psi(t/n) \) for all \( t \geq 0 \), so we may choose \( \beta_i = 1/n \) for all \( i \) in (B).

6. Uniqueness of Y-Coincidence Points

Consider on the product space \( X^n \) the following partial order:

for \( (x_1, x_2, ..., x_n), (y_1, y_2, ..., y_n) \in X^n \),

\[
(x_1, x_2, ..., x_n) \leq (y_1, y_2, ..., y_n) \iff x_i \leq y_i, \forall i.
\]  

(58)

We say that \( (x_1, x_2, ..., x_n) \) and \( (y_1, y_2, ..., y_n) \) are comparable if \( (x_1, x_2, ..., x_n) \leq (y_1, y_2, ..., y_n) \) or \( (x_1, x_2, ..., x_n) \geq (y_1, y_2, ..., y_n) \).

Theorem 30. Under the hypothesis of Theorem 24, assume that for all Y-coincidence points \( (x_1, x_2, ..., x_n) \), \((y_1, y_2, ..., y_n) \in X^n \) of \( F \) and \( g \) there exists \( (u_1, u_2, ..., u_n) \in X^n \) such that \((gu_1, gu_2, ..., gu_n)\) is comparable, at the same time, to \((gx_1, gx_2, ..., gx_n)\) and to \((gy_1, gy_2, ..., gy_n)\). Then, \( F \) and \( g \) have a unique Y-coincidence point \((z_1, z_2, ..., z_n) \in X^n \) such that \( gz_i = z_i \) for all \( i \).

Proof. From Theorem 24, the set of Y-coincidence points of \( F \) and \( g \) is nonempty. The proof is divided into two steps.

Step 1. We claim that if \( (x_1, x_2, ..., x_n), (y_1, y_2, ..., y_n) \in X^n \) are two Y-coincidence points of \( F \) and \( g \), then

\[
gx_i = gy_i, \forall i.
\]  

(59)

Let \( (x_1, x_2, ..., x_n), (y_1, y_2, ..., y_n) \in X^n \) be two Y-coincidence points of \( F \) and \( g \), and let \( (u_1, u_2, ..., u_n) \in X^n \) be a point such that \((gu_1, gu_2, ..., gu_n)\) is comparable, at the same time, to \((gx_1, gx_2, ..., gx_n)\) and to \((gy_1, gy_2, ..., gy_n)\). Using \( (u_1, u_2, ..., u_n) \), define the following sequences. Let \( u_0^i = u_i \) for all \( i \). Reasoning as in Theorem 24, we can determine sequences \( \{u_m^1\}_{m=0}^{\infty}, \{u_m^2\}_{m=0}^{\infty}, ..., \{u_m^n\}_{m=0}^{\infty} \) such that \( gu_{m+1}^i = F(u_m^1, u_m^2, ..., u_m^n) \) for all \( i \) and all \( m \). We are going to prove that \( gx_i = \lim_{m \to \infty} gu_m^i = gy_i \) for all \( i \), so (59) will be true.

Firstly, we reason with \((gu_1, gu_2, ..., gu_n)\) and \((gx_1, gx_2, ..., gx_n)\), and the same argument holds for \((gu_1, gu_2, ..., gu_n)\) and \((gy_1, gy_2, ..., gy_n)\). As \((gu_1, gu_2, ..., gu_n)\) and \((gx_1, gx_2, ..., gx_n)\) are comparable, we can suppose that \((gu_1, gu_2, ..., gu_n) \leq (gx_1, gx_2, ..., gx_n)\) (the other case is similar); that is, \( gu_i \leq gx_i \) for all \( i \). Using that \( F \) has the mixed \( g \)-monotone property and reasoning as in Theorem 24, it is possible to prove that \( gu_m \leq gx_i \) for all \( m \geq 1 \) and all \( i \). This condition implies that, for all \( m \) and \( i \)

\[
either \quad [gu_m^i \leq gx_i \quad \forall i] \quad \text{or} \quad [gx_i \leq gu_m^i \quad \forall i].
\]  

(60)

Define \( \beta_m = \max_{1 \leq i \leq n} p(gu_m^i, gx_i) \) for all \( m \). Reasoning as in Theorem 24, it is not difficult to prove that

\[
\{\beta_m\}_{m \geq 1} \to 0 \quad \text{which means that} \quad \lim_{m \to \infty} \beta_m = \lim_{m \to \infty} (\max_{1 \leq i \leq n} p(gu_m^i, gx_i)) = 0.
\]

As \( 0 \leq p(gu_m^i, gx_i) \leq \beta_m \) for all \( m \) and all \( i \), we deduce that \( \{p(gu_m^i, gx_i)\}_{m \geq 1} \to 0 \) for all \( i \); that is, \( \{gu_m^i\} \rightharpoonup gx_i \) for all \( i \). Item 1 of Lemma 20 shows that

\[
\{gu_m^i\} \rightharpoonup gx_i \quad \forall i.
\]  

(61)

If we had supposed that \((gx_1, gx_2, ..., gx_n) \leq (gu_1, gu_2, ..., gu_n)\), we would have obtained the same property (61). And as \((gu_1, gu_2, ..., gu_n)\) also is comparable to \((gy_1, gy_2, ..., gy_n)\), we can reason in the same way to prove that \( \{gu_m^j\} \rightharpoonup gj_i \) for all \( i \). Since the limit in a MS is unique, \( gx_i = gj_i \) for all \( i \).

Let \((x_1, x_2, ..., x_n) \in X^n \) be a Y-coincidence point of \( F \) and \( g \), and define \( z_i = gx_i \) for all \( i \). As \((z_1, z_2, ..., z_n) = (gx_1, gx_2, ..., gx_n)\), Remark 6 assures us that \((z_1, z_2, ..., z_n)\) also is a Y-coincidence point of \( F \) and \( g \).

Step 2. We claim that \((z_1, z_2, ..., z_n)\) is the unique Y-coincidence point of \( F \) and \( g \) such that \( gz_i = z_i \) for all \( i \). It is similar to Step 2 in Theorem 11 in [11].

It is natural to say that \( g \) is injective on the set of all Y-coincidence points of \( F \) and \( g \) when \( gx_i = gy_i \) for all \( i \) implies \( x_i = y_i \) for all \( i \). When \((x_1, x_2, ..., x_n), (y_1, y_2, ..., y_n) \in X^n \) are two Y-coincidence points of \( F \) and \( g \), for example, this is true if \( g \) is injective on \( X \).

Corollary 31. In addition to the hypotheses of Theorem 30, suppose that \( g \) is injective on the set of all Y-coincidence points of \( F \) and \( g \). Then, \( F \) and \( g \) have a unique Y-coincidence point.

Proof. If \((x_1, x_2, ..., x_n), (y_1, y_2, ..., y_n) \in X^n \) are two Y-coincidence points of \( F \) and \( g \), we have proved in (59) that \( gx_i = gy_i \) for all \( i \). As \( g \) is injective on these points, then, \( x_i = y_i \) for all \( i \).

Corollary 32. In addition to the hypotheses of Theorem 30, suppose that \((z_{a(1)}, z_{a(2)}, ..., z_{a(n)})\) is comparable to \((z_{a(1)}, z_{a(2)}, ..., z_{a(n)})\) for all \( i \). Then, \( z_1 = z_2 = \cdots = z_n \).

In particular, there exists a unique \( z \in X \) such that \( F(z, z, ..., z) = z \), which verifies \( gz = z \).

Proof. Let \( M = \max_{1 \leq i \leq n} p(z_i, z_1), \) let \( j_0, s_0 \in \{1, 2, ..., n\} \) such that \( p(z_{j_0}, z_{s_0}) = M \), and let

\[
\Lambda = \max_{1 \leq i \leq n} p(z_{a(i)}, z_{a(i)}) \leq M.
\]  

(62)
Fix $j, s \in \{1, 2, \ldots, n\}$. As $(z_{\sigma(j)}, z_{\sigma(j)}, \ldots, z_{\sigma(j)})$ is comparable to $(z_{\sigma(j)}, z_{\sigma(j)}, \ldots, z_{\sigma(j)})$, then either $z_{\sigma(j)} \preceq z_{\sigma(j)}$ for all $i$ or $z_{\sigma(j)} \preceq z_{\sigma(j)}$ for all $i$. Since $g z_i = z_i$ for all $i$, we know that either $g z_{\sigma(j)} \preceq g z_{\sigma(j)}$ for all $i$ or $g z_{\sigma(j)} \preceq g z_{\sigma(j)}$ for all $i$. In any case, applying (17),

$$
\psi(M) = \psi(p(z_j, z_n)) = \psi(p(g z_j, g z_n)) = \psi(p(F(z_{\sigma(1)}, z_{\sigma(2)}, \ldots, z_{\sigma(n)}), F(z_{\sigma(1)}, z_{\sigma(2)}, \ldots, z_{\sigma(n)})))
$$

(63)

If $\Lambda > 0$, then $\phi(\Lambda) > 0$, so $\psi(M) \leq \psi(M) - \phi(\Lambda) < \psi(M)$, which is impossible. Then, $\Lambda = 0$, and (63) implies that $\psi(M) \leq \psi(\Lambda) - \phi(\Lambda) = \psi(0) - \phi(0) = 0$, so $\psi(M) = 0$.

Therefore, $p(z_j, z_i) = 0$ for all $i$ and $j$. □

Example 33. Let $X = \mathbb{R}$ provided with its usual partial order $\preceq$ and the partial metric $p(x, y) = \max(|x|, |y|)$. Let $n \in \mathbb{N}$, and let $a_1, a_2, \ldots, a_n \in \mathbb{R} \setminus \{0\}$ real numbers such that there exist $i_0, j_0 \in \{1, 2, \ldots, n\}$ verifying $a_{i_0} < 0 < a_{i_0}$. Let $N > |a_1| + |a_2| + \cdots + |a_n|$, and consider $F(x_1, x_2, \ldots, x_n) = (a_1 x_1 + a_2 x_2 + \cdots + a_n x_n) / N$ and $g x = x$, for all $x, x_1, x_2, \ldots, x_n \in X$. Then, $F$ is monotone nondecreasing in those arguments for which $a_i > 0$ and monotone nonincreasing in those arguments for which $a_i < 0$. Furthermore, taking $k = (|a_1| + |a_2| + \cdots + |a_n|) / N \in (0, 1)$, it follows that

$$
|F(x_1, x_2, \ldots, x_n)| \\
\leq \frac{|a_1| |x_1| + |a_2| |x_2| + \cdots + |a_n| |x_n|}{N} \\
\leq \frac{|a_1| + |a_2| + \cdots + |a_n|}{N} \max(|x_1|, |x_2|, \ldots, |x_n|) \\
= k \max(|x_1|, |x_2|, \ldots, |x_n|).
$$

(64)

Therefore,

$$
p(F(x_1, x_2, \ldots, x_n), F(y_1, y_2, \ldots, y_n)) \\
= \max(|F(x_1, x_2, \ldots, x_n)|, |F(y_1, y_2, \ldots, y_n)|) \\
\leq k \max(|x_1|, |x_2|, \ldots, |x_n|), \\
\leq k \max(|y_1|, |y_2|, \ldots, |y_n|).
$$

(65)

If $\psi(t) = t$ and $\phi(t) = (1 - k)t$, all conditions of Theorems 24 and 30 (and Corollaries 31 and 32) are satisfied. Indeed, it is clear that $(0, 0, \ldots, 0)$ is the unique fixed point of $F$.

The following example is based on Examples 1.9 and 2.2 in [29].

Example 34. Let $X = \{0, 1, 2, 3, 4\}$, and let $p$ be the partial metric on $X$ given by $p(x, y) = \max(x, y)$ for all $x, y \in X$. Then, $(X, p)$ is complete, and $p$ generates the discrete topology on $X$ (indeed, $d_p$ is the Euclidean metric on $X$). Consider on $X$ the following partial order:

$$
x, y \in X, \quad x \preceq y \iff x = y \quad \text{or} \quad (x, y) = (0, 2).
$$

(66)

Consider $F : X^n \to X$ and $g : X \to X$ defined by

$$
F(x_1, x_2, \ldots, x_n) = \begin{cases} 0, & \text{if } x_1, x_2, \ldots, x_n \in \{0, 1, 2\}, \\
1, & \text{otherwise}, \\
g x & \text{otherwise}.
\end{cases}
$$

(67)

It is not difficult to prove the following statements.

1. $F$ and $g$ are $d_p$-continuous mappings (since $d_p$ generates the discrete topology on $X$).
2. $F$ and $g$ are commuting.
3. If $y, z \in X$ verify $g y \preceq g z$, then either $y, z \in \{0, 1, 2\}$ or $y, z \in \{3, 4\}$. Then, $F$ has the mixed $(g, \preceq)$-monotone property on $X$.
4. If $x_1, x_2, \ldots, x_n, y_1, y_2, \ldots, y_n \in X$ verify $g x_i \preceq g y_i$ for all $i$, then $F(x_1, x_2, \ldots, x_n) = F(y_1, y_2, \ldots, y_n)$. In particular, (17) holds (whatever $\psi$ and $\phi$; for instance, $\psi(t) = 2t$ and $\phi(t) = \log(t + 1)$ for all $t \geq 0$).

For simplicity, henceforth, suppose that $n$ is even, and let $A$ (resp., $B$) be the set of all odd (resp., even) numbers in $\{1, 2, \ldots, n\}$.

5. For a mapping $\sigma : A_n \to A_n$, we use the notation $\sigma = (\sigma(1), \sigma(2), \ldots, \sigma(n))$ and consider

$$
\sigma_i = (i, i + 1, \ldots, n - 1, n, 1, 2, \ldots, i - 1) \quad \forall i.
$$

(68)

Then, $\sigma_i \in \Omega_{A_B}$ if $i$ is odd, and $\sigma_i \in \Omega_{A_B}$ if $i$ is even. Let $Y = (\sigma_1, \sigma_2, \ldots, \sigma_n)$.

6. Take $x_0 = 0$ if $i$ is odd and $x_0 = 2$ if $i$ is even. Then, $g x_0 \leq F(x_{\sigma(1)}, x_{\sigma(2)}, \ldots, x_{\sigma(n)})$ for all $i$.

7. $(X, d_p, \preceq)$ has the sequential $g$-monotone property.

Therefore, we can apply Theorems 24 and 30, and Corollaries 31 and 32, to conclude that $F$ and $g$ have a unique $Y$-coincidence point, which is $(0, 0, \ldots, 0)$.

The purpose of this paper is to give a new modified Ishikawa type iteration algorithm for common fixed points of total asymptotically strict pseudocontractive semigroups. Under the reduction of some conditions, both strong convergence and weak convergence of the iteration algorithm are proved in Banach spaces with new methods of proofs, respectively. The main results presented in this paper extend and improve the corresponding recent results of many others.

1. Introduction

Throughout this paper, we assume that $E$ is a real Banach space with the norm $\| \cdot \|$, $E^*$ the dual space of $E$, $\langle \cdot, \cdot \rangle$ the duality between $E$ and $E^*$, and $C$ a nonempty closed convex subset of $E$. $\mathbb{R}^+$ denotes the set of nonnegative real numbers and $\mathbb{N}$ the natural number set. The mapping $J : E \to 2^{E^*}$ with

$$\mathcal{J}(x) = \{ f^* \in E^* : \langle x, f^* \rangle = \| x \|^2, \| f^* \| = \| x \| \}, \quad x \in E, \quad (1)$$

is called the normalized duality mapping.

Let $T : C \to C$ be a nonlinear mapping. $F(T)$ denotes the set of the fixed points of $T$.

As we know, a mapping $T : C \to C$ is said to be pseudocontractive, if, for all $x, y \in C$, there exists $j(x - y) \in J(x - y)$, such that

$$\langle Tx - Ty, j(x - y) \rangle \leq \| x - y \|^2. \quad (2)$$

Variational inequalities introduced by Stampacchia in the early sixties have had a great impact and influence on the development of almost all branches of pure and applied sciences and have witnessed an explosive growth in theoretical advantages, algorithmic development, and so forth.

Recently, some authors also studied the problem of finding the solution set of variational inequalities and the common element of the fixed point set for generalized nonexpansive mappings in the framework of real Hilbert spaces and Banach spaces. As is known to all, the variational inequality problem, nonlinear optimization problem, and fixed point problem are equivalent to each other under certain conditions.

In 2012, Chang et al. [1] introduced a more general class of pseudocontractive mappings and studied the methods for approximation of the split common fixed points.

Definition 1 (see [1]). (I) A mapping $T : C \to C$ is said to be $(\gamma, \mu_n, \xi_n, \phi)$-totally asymptotically strictly pseudocontractive, if there exist a constant $\gamma \in [0, 1)$ and sequences $\{\mu_n\}$, $\{\xi_n\} \subset [0, \infty)$ with $\mu_n \to 0$ and $\xi_n \to 0$, such that, for all $x, y \in C$,

$$\| T^nx - T^ny \|^2 \leq \| x - y \|^2 + \gamma \| (I - T^n)x - (I - T^n)y \|^2$$

$$+ \mu_n \phi(\| x - y \|) + \xi_n, \quad \forall n \geq 1, \quad (3)$$

where $\phi : [0, \infty) \to [0, \infty)$ is a continuous and a strictly increasing function with $\phi(0) = 0$.

(II) A mapping $T : C \to C$ is said to be $(\gamma, k_n)$-asymptotically strictly pseudocontractive, if there exist
a constant \( y \in [0, 1) \) and a sequence \( k_n \subset [1, \infty) \) with \( k_n \to 1 \), such that

\[
\|T^n x - T^m y\|^2 \leq k_n \|x - y\|^2 + \gamma \|(I - T^m)x - (I - T^n)y\|^2, \quad \forall x, y \in C.
\]  

Definition 2. (I) One-parameter family \( \mathcal{T} := \{T(t) : C \to C, t \geq 0\} \) is said to be a pseudocontractive semigroup on \( C \), if the following conditions are satisfied:

(a) \( T(0)x = x \) for each \( x \in C \);
(b) \( T(t + s)x = T(t)T(s)x \) for any \( t, s \in \mathbb{R}^+ \) and \( x \in C \);
(c) the mapping \( t \to T(t)x \) is continuous for any given \( x \in C \);
(d) for any \( t \geq 0 \), \( T(t) \) is pseudocontractive; that is, for any \( x, y \in C \), there exists \( j(x - y) \in J(x - y) \), such that

\[
\langle T^n(t)x - T^n(t)y, j(x - y) \rangle \leq \|x - y\|^2. \tag{5}
\]

(ii) One-parameter family \( \mathcal{T} := \{T(t) : C \to C, t \geq 0\} \) is said to be strict pseudocontractive semigroup on \( C \), if the conditions (a)–(c) and the following condition (e) are satisfied.

(e) For any \( x, y \in C \), there exist \( j(x - y) \in J(x - y) \) and a bounded function \( \eta : [0, \infty) \to [0, \infty) \) such that, for any \( t \geq 0 \),

\[
\langle T(t)x - T(t)y, j(x - y) \rangle \\
\leq \|x - y\|^2 - \eta(t) \|(x - y) - (T(t)x - T(t)y)\|^2.
\]  

(II) One-parameter family \( \mathcal{T} := \{T(t) : C \to C, t \geq 0\} \) is said to be strict pseudocontractive semigroup on \( C \), if the conditions (a)–(c) and the following condition (e) are satisfied.

(e) For any \( x, y \in C \), there exist \( j(x - y) \in J(x - y) \) and a bounded function \( \eta : [0, \infty) \to [0, \infty) \) such that, for any \( t \geq 0 \),

\[
\langle T^n(t)x - T^n(t)y, j(x - y) \rangle \\
\leq k_n \|x - y\|^2 - \eta(t) \|(x - y) - (T^n(t)x - T^n(t)y)\|^2.
\]  

Osilike and Akuchu [2] established an iterative scheme for approximation of common fixed points of a finite family of asymptotically pseudocontractive mappings. Miao et al. [3] introduced an implicit iteration process for a finite family of total asymptotically pseudocontractive maps. And in recent years, many researchers focused on the convergence of pseudocontractive and asymptotically strict pseudocontractive semigroups; see [4–8] and their references. In [9, 10] especially, the authors gave the modified Mann type iteration algorithm and studied its convergence.

Inspired and motivated by the above works, in this paper, we give a new modified Ishikawa type iteration algorithm for total asymptotically strict pseudocontractive semigroups. Under the reduction of some conditions, we prove both strong convergence and weak convergence of the iteration algorithm by using the method of the subsequence of a subsequence of the sequence \( \{x_n\} \) in Banach spaces, respectively. The results presented in this paper extend and improve the corresponding recent results of many authors, such as [1, 7–10].

2. Preliminaries

This section contains some definitions, notations, and lemmas, which will be used in the proofs of our main results in the next section.

A Banach space \( E \) is said to be smooth if the limit \( \lim_{t \to 0}((\|x + ty\| - \|x\|)/t) \) exists for each \( x, y \in \{x \in E : \|x\| = 1\} \). It is well known that if \( E \) is reflexive and smooth, then the duality mapping \( J \) is single valued.

A Banach space \( E \) is said to have Opial condition if, for any sequence \( \{x_n\} \subset E \) weakly convergent to \( x_0 \in E \),

\[
\liminf_{n \to \infty} \|x_n - x_0\| < \liminf_{n \to \infty} \|x_n - x\\| \tag{8}
\]

holds for any \( x \neq x_0 \).

A mapping \( T \) is said to be demiclosed, if, for any sequence \( \{x_n\} \subset E \), \( x_n \rightharpoonup x \) and \( \|(I - T)x_n\| \to 0 \) imply that \( (I - T)y = 0 \).

Definition 3 (see [9]). One-parameter family \( \mathcal{T} := \{T(t) : C \to C, t \geq 0\} \) is said to be \( \eta \)-total asymptotically strict pseudocontractive semigroup on \( C \), if the conditions (a)–(c) in Definition 2 and the following condition (f) are satisfied.

(f) There exist a bounded function \( \eta : [0, \infty) \to [0, \infty) \) and sequences \( \{\mu_n\} \subset [0, \infty) \) and \( \{\xi_n\} \subset [0, \infty) \) with \( \mu_n \to 0, \xi_n \to 0, \) as \( n \to \infty \). For any given \( x, y \in C \), there exists \( j(x - y) \in J(x - y) \) such that, for any \( t \geq 0 \),

\[
\langle T^n(t)x - T^n(t)y, j(x - y) \rangle \\
\leq \|x - y\|^2 - \eta(t) \|(x - y) - (T^n(t)x - T^n(t)y)\|^2 + \mu_n \phi(\|x - y\|) + \xi_n, \tag{9}
\]

for any \( t \geq 0 \), for all \( n \geq 1 \), where \( \phi : [0, \infty) \to [0, \infty) \) is continuous and strictly increasing function with \( \phi(0) = 0 \).

A \( \eta \)-total asymptotically strict pseudocontractive semigroup is said to be uniformly Lipschitzian, if there exists a bounded measurable function \( L : [0, \infty) \to (0, \infty) \), such that

\[
\|T^n(t)x - T^n(t)y\| \\
\leq L(t) \|x - y\|, \quad \forall x, y \in C, t \geq 0, n \in \mathbb{N}. \tag{10}
\]
Remark 4. According to the definitions, it is obvious that a pseudocontractive semigroup is a strict pseudocontractive semigroup with \( \eta(t) = 0 \), and a strict pseudocontractive semigroup is an asymptotically strict pseudocontractive semigroup with \( k_n = 1 \). An asymptotically strict pseudocontractive semigroup is a \( (\eta, \{\mu_n\}, \{\xi_n\}, \phi) \)-total asymptotically strict pseudocontractive semigroup with \( \phi(t) = t^2 \), \( \mu_n = k_n - 1 \), and \( \xi_n = 0 \).

Definition 5 (see [11]). The normalized duality mapping \( J \) of a Banach space \( E \) is said to be weakly sequentially continuous; if for all \( \{x_n\} \subset E, x_n \rightharpoonup x \), then there exist \( j(x_n) \in J(x_n) \), \( j(x) \in J(x) \) such that \( j(x_n) \rightharpoonup j(x) \), where weak convergence and weak star convergence are denoted by \( \rightharpoonup \) and \( \rightharpoonup^* \), respectively.

In order to prove the main results of this paper, the following lemmas should be used.

Lemma 6 (see [4]). For any \( x, y \in E \), one has
\[
\|x + y\|^2 \leq \|x\|^2 + 2 \langle y, j(x - y) \rangle, \\
\forall j(x - y) \in J(x - y).
\]

Lemma 7 (see [12]). Let \( \{a_n\} \), \( \{b_n\} \), and \( \{\delta_n\} \) be the sequences of \( \mathbb{R}^+ \), which satisfy
\[
a_{n+1} \leq (1 + \delta_n) a_n + b_n, \quad \forall n \geq 1. \tag{12}
\]
If \( \sum_{n=1}^{\infty} \delta_n < \infty \), \( \sum_{n=1}^{\infty} b_n < \infty \), then the limit \( \lim_{n \to \infty} a_n \) exists.

3. Main Results

Theorem 8. Let \( C \) be a nonempty closed convex subset of a real Banach space \( E \), and let \( T : \{T(t) : C \to C, t \geq 0\} \) be a uniformly Lipschitzian and \( (\eta, \{\mu_n\}, \{\xi_n\}, \phi) \)-total asymptotically strict pseudocontractive semigroup defined in Definition 3. Suppose that \( F(T) := \bigcap_{t \geq 0} F(T(t)) \neq \emptyset \) and there exists a compact subset \( K \) of \( E \) such that \( \bigcap_{t \geq 0} T(t)(C) \subseteq K \). We assume that there exist positive constants \( M \) and \( M^* \), such that \( \phi(x) \leq M^* x^2 \) for all \( x \geq M \). Let \( \{x_n\} \) be the sequence defined by the modified Ishikawa type iteration algorithm:
\[
x_1 \in C, \quad \text{chosen arbitrarily,} \\
y_n = (1 - \beta_n) x_n + \beta_n T^n(t) x_n, \\
x_{n+1} = (1 - \alpha_n) x_n + \alpha_n T^n(t) y_n.
\]
Then \( \{x_n\} \) converges strongly to a common fixed point \( x^* \in F(T) \) in \( C \), if the following conditions are satisfied:

(i) \( \sum_{n=1}^{\infty} \alpha_n^2 < \infty \), \( \sum_{n=1}^{\infty} \alpha_n = \infty \), \( \sum_{n=1}^{\infty} \alpha_n \mu_n < \infty \), and \( \sum_{n=1}^{\infty} \alpha_n \xi_n < \infty \);

(ii) \( \beta_n \to 0 \) as \( n \to \infty \), \( \sum_{n=1}^{\infty} \alpha_n \beta_n < \infty \);

(iii) \( \eta = \inf_{t \geq 0} \eta(t) > 0 \), \( L = \sup_{t \geq 0} L(t) < +\infty \).

Proof. We divide the proof into four steps.

Step 1. Firstly, we prove that \( \lim_{n \to \infty} \|x - p\| \) exists for any \( p \in F(T) \).

By the definitions of \( T(t) \) and \( \{x_n\} \), we have
\[
\|T^n(t)x_n - p\| \leq L \|x_n - p\|, \\
\|y_n - p\| = \|(1 - \beta_n)x_n + \beta_n T^n(t)x_n - p\| \\
\leq (1 - \beta_n) \|x_n - p\| + \beta_n \|T^n(t)x_n - p\| \\
\leq (1 - \beta_n + \beta_n L) \|x_n - p\| \\
\leq (1 + L) \|x_n - p\|, \\
\|T^n(t)y_n - p\| \leq L \|y_n - p\| \leq L (1 + L) \|x_n + p\|.
\]

This follows from that
\[
\|x_{n+1} - p\| = \|(1 - \alpha_n)x_n + \alpha_n T^n(t)y_n - p\| \\
\leq (1 - \alpha_n) \|x_n - p\| + \alpha_n \|T^n(t)y_n - p\| \\
\leq (1 - \alpha_n) \|x_n - p\| + \alpha_n L (1 + L) \|x_n - p\| \\
\leq (1 + L + L^2) \|x_n - p\|, \\
\|y_n - x_n\| = \|(1 - \beta_n)x_n + \beta_n T^n(t)x_n - x_n\| \\
= \beta_n \|x_n - T^n(t)x_n\| \\
\leq \beta_n (\|x_n - p\| + \|T^n(t)x_n - p\|) \\
\leq \beta_n (1 + L) \|x_n - p\|, \\
\|T^n(t)y_n - x_n\| \leq \|T^n(t)y_n - p\| + \|x_n - p\| \\
\leq (1 + L + L^2) \|x_n - p\|, \\
\|x_{n+1} - x_n\| = \|(1 - \alpha_n)x_n + \alpha_n T^n(t)y_n - x_n\| \\
\leq \alpha_n \|T^n(t)y_n - x_n\| \\
\leq \alpha_n (1 + L + L^2) \|x_n - p\|. \tag{15}
\]

Since \( F(T) := \{T(t) : C \to C, t \geq 0\} \) is total asymptotically strict pseudocontractive semigroup, for any point \( x_{n+1} \in C \) and \( p \in F(T) \), by (9), we have
\[
\langle T^n(t)x_{n+1} - x_{n+1}, j(x_{n+1} - p) \rangle \\
\leq - \eta(t) \|T^n(t)x_{n+1} - x_{n+1}\| + \mu_n \phi(\|x_{n+1} - p\|) + \xi_n. \tag{16}
\]

Since \( \phi \) is an increasing function, it results in that \( \phi(x) \leq \phi(M) \), if \( x \leq M \); \( \phi(x) \leq M^* x^2 \), if \( x \geq M \). In either case, we can obtain that
\[
\phi(x) \leq \phi(M) + M^* x^2. \tag{17}
\]
Hence, by Lemma 6, we have
\[
\|x_{n+1} - p\|^2 \\
= \|x_n - p + \alpha_n (T^n (t) y_n - x_n)\|^2 \\
\leq \|x_n - p\|^2 + 2\alpha_n \langle T^n (t) y_n - T^n (t) x_n, j (x_{n+1} - p) \rangle \\
+ 2\alpha_n \langle T^n (t) x_n - T^n (t) x_{n+1}, j (x_{n+1} - p) \rangle \\
+ 2\alpha_n \langle T^n (t) x_{n+1} - x_{n+1}, j (x_{n+1} - p) \rangle \\
+ 2\alpha_n \langle x_{n+1} - x_{n+1}, j (x_{n+1} - p) \rangle \\
\leq \|x_n - p\|^2 + 2\alpha_n \|y_n - x_n\| \cdot \|x_{n+1} - p\| \\
+ 2\alpha_n \|x_n - x_{n+1}\| \cdot \|x_{n+1} - p\| \\
- 2\alpha_n \eta(t) \|T^n(t) x_{n+1} - x_{n+1}\|^2 \\
+ 2\alpha_n \|x_n - x_{n+1}\| \cdot \|x_{n+1} - p\| \\
+ 2\alpha_n \|\phi\| \|x_{n+1} - p\| + 2\alpha_n \xi_n \\
\leq \|x_n - p\|^2 + 2\alpha_n \beta_n L (1 + L) (1 + L + L^2) \|x_n - p\|^2 \\
+ 2\alpha_n (1 + L + L^2) \|x_n - p\|^2 \\
- 2\alpha_n \eta(t) \|T^n(t) x_{n+1} - x_{n+1}\|^2 \\
+ 2\alpha_n (1 + L + L^2) \|x_n - p\|^2 \\
+ 2\alpha_n \mu_n [\phi (M) + M^* (1 + L + L^2) \|x_n - p\|^2] \\
+ 2\alpha_n \xi_n \\
= (1 + \delta_n) \|x_n - p\|^2 + b_n, \\
\tag{18}
\]}

where \(\delta_n = [2\alpha_n \beta_n L (1 + L) + 4\alpha_n (1 + L + L^2) + 2M^* \alpha_n \mu_n] (1 + L + L^2), b_n = 2\alpha_n \mu_n \phi (M) + 2\alpha_n \xi_n.\)

By the conditions (i) and (ii), we have \(\sum_{n=1}^{\infty} \delta_n < \infty, \sum_{n=1}^{\infty} b_n < \infty.\) Thus, by Lemma 7, we can obtain that \(\lim_{n \to \infty} \|x_n - p\|\) exists.

Step 2. Now we prove that \(\liminf_{n \to \infty} \|x_n - T^n (t) x_n\| = 0.\)

From (18), we know that
\[
2\alpha_n \eta(t) \|T^n(t) x_{n+1} - x_{n+1}\|^2 \\
\leq (\|x_n - p\|^2 - \|x_{n+1} - p\|^2) + \delta_n \|x_n - p\|^2 + b_n. \\
\tag{19}
\]

As \(\eta = \inf_{t \geq 0} \eta(t) > 0, A = \sup_n \|x_n - p\| < \infty,\) we can have
\[
\sum_{n=1}^{N} 2\alpha_n \eta \|T^n(t) x_{n+1} - x_{n+1}\|^2 \\
\leq \sum_{n=1}^{N} [(\|x_n - p\|^2 - \|x_{n+1} - p\|^2) + \delta_n A^2 + b_n] \\
\leq \|x_1 - p\|^2 + A^2 \sum_{n=1}^{N} \delta_n + \sum_{n=1}^{N} b_n, \\
\tag{20}
\]

and \(\lim_{n \to \infty} \alpha_n = 0,\) we have
\[
\liminf_{n \to \infty} \|x_n - T^n (t) x_n\| = 0. \\
\tag{25}
\]

Step 3. Now we prove that \(\liminf_{n \to \infty} \|x_n - T(t) x_n\| = 0.\)
Consider
\[
\|x_{n+1} - T(t)x_{n+1}\|
\leq \|x_{n+1} - T^{n+1}(t)x_{n+1}\|
+ \|T^{n+1}(t)x_{n+1} - T(t)x_{n+1}\|
\leq \|x_{n+1} - T^{n+1}(t)x_{n+1}\|
+ L\|T^n(t)x_{n+1} - x_{n+1}\|
\leq \|x_{n+1} - T^{n+1}(t)x_{n+1}\|
+ L\left(\|T^n(t)x_{n} - T^n(t)x_n\| + \|T^n(t)x_n - x_n\| \right)
\leq \|x_{n+1} - T^{n+1}(t)x_{n+1}\| + L\|T^n(t)x_n - x_n\|
+ L\|x_n - x_n\|
\leq \|x_{n+1} - T^{n+1}(t)x_{n+1}\| + L\|x_n - x_n\| + \alpha_n L(1 + L)(1 + L + L^2) A.
\]
Since \(\lim_{n \to \infty} \alpha_n = 0\) and (25), we have
\[
\lim_{n \to \infty} \|x_n - T(t)x_n\| = 0.
\]
Thus, there exists a subsequence \(\{x_{n_k}\} \subseteq \{x_n\}\) such that
\[
\lim_{k \to \infty} \|x_{n_k} - T(t)x_{n_k}\| = 0.
\]

**Step 4.** Finally, we prove the sequence \(\{x_n\}\) converges strongly to a common fixed point of the semigroup \(\mathcal{S} := \{T(t) : C \to C, t \geq 0\}\).

Since \(K\) is a compact subset of \(E\) and \(\bigcap_{t \geq 0} T(t)(C) \subseteq K\), just as the proof in [9, 10], there exists a subsequence \(\{x_{n_k}\} \subseteq \{x_n\}\) such that \(T(t)x_{n_k} \to x^* \in K\). From (28), we have
\[
\lim_{k \to \infty} \|T(t)x_{n_k} - x_{n_k}\| = 0,
\]
and
\[
\|x_{n_k} - x^*\| \leq \|x_{n_k} - T(t)x_{n_k}\| + \|T(t)x_{n_k} - x^*\| \to 0.
\]
Hence we have that
\[
\|T(t)x^* - x^*\| = \lim_{n_k \to \infty} \|x_{n_k} - T(t)x_{n_k}\| = 0.
\]
That is, \(x^* \in F(\mathcal{S})\).

Since, for each \(p \in F(\mathcal{S})\), \(\lim_{n \to \infty}\|x_{n_k} - p\|\) exists, \(\lim_{n \to \infty}\|x_{n_k} - x^*\| = 0\), and \(\{x_{n_k}\} \subseteq \{x_n\}\), so we have \(\lim_{n \to \infty}\|x_{n_k} - p\| = 0\); that is, \(x_n\) converges strongly to an element \(x^* \in F(\mathcal{S})\).

**Remark 9.** (a) If we take \(\beta_n = 0\) in the modified Ishikawa type iteration algorithm (33), then (33) is called the modified Mann type iteration algorithm in many articles, such as in [9, 10].

(b) In Theorem 8, because there is no limit to \(t\) of \(T(t)\), so our result is stronger and the conditions here are less than in [9, 10]. For example, the conditions “for any bounded subset \(D \subseteq C\),
\[
\lim_{n \to \infty} \sup_{x \in D, t \in \mathbb{R}^+} \|T^n(s + t_n) x - T^n(t_n) x\| = 0
\]
(31) in [9, 10] can be removed in Theorem 8. (c) The condition “there exists a compact subset \(K\) of \(E\) such that \(\bigcap_{t \geq 0} T(t)(C) \subseteq K\)” does not look natural. But it is easy to see that this condition is established naturally when we assume \(C\) is a compact subset of \(E\). So, the result in Theorem 8 is still true if this condition is replaced by the condition “let \(C\) be a compact subset of \(E\)” if there is no compactness assumption, we can get the following weak convergence theorem.

**Theorem 10.** Let \(E\) be a reflexive Banach space satisfying the opial condition and \(C\) be a nonempty bounded closed convex subset of \(E\). Let \(\mathcal{S} := \{T(t) : C \to C, t \geq 0\}\) be a uniformly Lipschitzian and \((\{\eta_k\}, \{\xi_k\}, \phi\)-total asymptotically strict pseudocontractive semigroup defined by Definition 3. Suppose that there exist positive constants \(M\) and \(M^*\), such that \(\phi(x) \leq M^* x^2\) for all \(x \geq M\), and \(F(\mathcal{S}) = \bigcap_{t \geq 0} F(T(t)) \neq \emptyset\). Let \(\{x_n\}\) be the sequence defined by (13). Then \(\{x_n\}\) converges weakly to a common fixed point \(x^* \in F(\mathcal{S})\) in \(C\), if the following conditions are satisfied.

(i) \(\sum_{n=1}^{\infty} \alpha_n < \infty\), \(\sum_{n=1}^{\infty} \beta_n < \infty\), \(\sum_{n=1}^{\infty} \alpha_n \mu_n < \infty\), \(\sum_{n=1}^{\infty} \alpha_n \beta_n < \infty\).

(ii) \(\beta_n \to 0\) as \(n \to \infty\), and \(\sum_{n=1}^{\infty} \alpha_n \beta_n < \infty\).

(iii) \(\lambda = \inf_{t \geq 0} \lambda(t) > 0\), \(L = \sup_{t \geq 0} L(t) < +\infty\).

**Proof.** It can be proved just like the proof in Theorem 8 that, for each \(p \in F(\mathcal{S})\), \(\lim_{n \to \infty}\|x_{n_k} - p\|\) exists, and, for all \(t > 0\), \(T(t)x_n\) is bounded, \(\lim_{n \to \infty}\|T(t)x_{n_k} - x_{n_k}\| = 0\). Thus, there exists a subsequence \(\{x_{n_k}\} \subseteq \{x_n\}\) such that \(\lim_{n \to \infty}\|x_{n_k} - T(t)x_{n_k}\| = 0\).

Now we prove that \(I - T(t)\) is demiclosed at zero (see [11]).

Since \(C\) is a closed and convex subset of a reflexive Banach space \(E\), there exists a subsequence \(\{x_{n_k}\} \subseteq \{x_n\}\) such that \(x_{n_k} \rightharpoonup x^* \in C\). Without loss of generality, we can assume that \(\{x_{n_k}\}\) replaces \(\{x_{n_k}\}\). Now in the following, we prove that \(x^* = T(t)x^*\).

Firstly, we choose \(\alpha \in (0, 1/(1 + L))\) and \(\gamma_m = (1 - \alpha)m + T^m(t)x\) for \(m \geq 1\). Since \(T(t)\) is uniformly Lipschitzian, we have
\[
\|x_{n} - T^m(t)x_{n}\| \leq \sum_{k=1}^{m-1} \|T(t)x_{n_k} - T^{k+1}(t)x_{n_k}\|
\leq \sum_{k=0}^{m-1} L\|x_n - T(t)x_n\|
= mL\|x_n - T(t)x_n\| \to 0, \quad n \to \infty.
\]

\[
\|x_{n+1} - T^n(t)x_{n+1}\| \to 0, \quad n \to \infty.
\]
Because \( T(t) \) is totally asymptotically strictly pseudocontractive, we have
\[
\langle (I - T^m(t)) y_m, J(x - y_m) \rangle = \langle (I - T^m(t)) y_m, J(x - y_m) - J(x_n - y_m) \rangle + \langle (I - T^m(t)) y_m, J(x_n - y_m) \rangle
\]
\[
= \langle (I - T^m(t)) y_m, J(x - y_m) - J(x_n - y_m) \rangle + \langle (I - T^m(t)) x_n, J(x_n - y_m) \rangle
\]
\[
+ \langle (I - T^m(t)) y_m - (I - T^m(t)) x_n, J(x_n - y_m) \rangle
\]
\[
\leq \langle (I - T^m(t)) y_m, J(x - y_m) - J(x_n - y_m) \rangle + \langle (I - T^m(t)) x_n, J(x_n - y_n) \rangle
\]
\[
+ \mu_n \phi(\|x_n - y_n\|) + \xi_n.
\]  (33)

Since \( x_n \to x^* \), \( \lim_{n \to \infty} \|x_n - T(t)x_n\| = 0 \) (note the \( x_n \) of here instead of \( x_n^* \)), and \( J \) is weakly sequential continuous duality mapping, we have
\[
\langle (I - T^m(t)) x^* - (I - T^m(t)) y_m, J(x^* - y_m) \rangle \leq (1 + L) \|x^* - y_m\|^2
\]  (34)
\[
\leq (1 + L) \alpha^2 \|x^* - T^m(t)x^*\|^2.
\]

Hence
\[
\|x^* - T^m(t)x^*\|^2 = \langle x^* - T^m(t)x^*, J(x^* - T^m(t)x^*) \rangle
\]
\[
= \frac{1}{\alpha} \langle x^* - T^m(t)x^*, J(x^* - y_m) \rangle
\]
\[
= \frac{1}{\alpha} \langle x^* - T^m(t)x^* - (y_m - T^m(t)y_m), J(x^* - y_m) \rangle + \frac{1}{\alpha} \langle y_m - T^m(t)y_m, J(x^* - y_m) \rangle
\]
\[
\leq \alpha \|x^* - T^m(t)x^*\|^2 + \frac{1}{\alpha} \mu_n M + \mu_n M^* (\text{diam } C) + \xi_n.
\]  (35)

This implies that
\[
\alpha (1 - \alpha (1 + L)) \|x^* - T^m(t)x^*\|^2 \leq \mu_n M + \mu_n M^* (\text{diam } C) + \xi_n, \quad \forall m \in \mathbb{N}.
\]  (36)

Let \( m \to \infty \); then we have \( \|x^* - T^m(t)x^*\| \to 0 \), as \( m \to \infty \), for \( \mu_n \to 0 \), \( \xi_n \to 0 \). Hence, \( T^m(t)x^* \to x^* \), as \( m \to \infty \), and \( T^{m+1}(t)x^* \to T(t)x^* \). By the continuity of \( T(t) \), we have \( T(t)x^* = x^* \).

Now, for the sequence \( \{x_n\} \) generated by (13), we prove that \( x_n \to x^* \).

Suppose the contrary; if there exists another subsequence \( \{x_{n_j}\} \subseteq \{x_n\} \), such that \( x_{n_j} \to y^* \) with \( y^* \neq x^* \), then we have that
\[
\lim_{n_j \to \infty} \|x_{n_j} - x^*\| \quad \text{and} \quad \lim_{n_j \to \infty} \|x_{n_j} - y^*\| \quad \text{exist.}
\]

Since \( E \) satisfies the Opial condition, we have
\[
\liminf_{n_j \to \infty} \|x_{n_j} - x^*\| < \lim_{n \to \infty} \|x_n - y^*\| = \lim_{n \to \infty} \|x_n - x^*\|.
\]  (37)

This is a contraction, which shows \( x^* = y^* \). Therefore, \( x_n \to x^* \in F(\mathcal{S}) \). This completes the proof. \( \square \)

**Remark II.** (a) Our results extend many other results that have been proved for this important class of general pseudocontractive mappings. For example, we extend the total asymptotically strict pseudocontractive mapping in [1] and Lipschitzian pseudo-contraction semigroup in [8] to the total asymptotically strict pseudocontractive semigroup. (b) In addition, we study the weak convergence of the total asymptotically strict pseudocontractive semigroup by using the demiclosedness of \( I - T(t) \) which, in some way, extends the result in [11] in Banach spaces. (c) And the method by using the subsequence of a subsequence of the sequence \( \{x_n\} \) in this paper is different from the previous references.

**Acknowledgments**

The authors would like to thank editors and referees for many useful comments and suggestions for the improvement of the paper. This work was partially supported by the Natural Science Foundation of Zhejiang Province (Y6100696) and the National Natural Science Foundation of China (11271330).

Recently, a worst-case $O(1/t)$ convergence rate was established for the Douglas-Rachford alternating direction method of multipliers (ADMM) in an ergodic sense. The relaxed proximal point algorithm (PPA) is a generalization of the original PPA which includes the Douglas-Rachford ADMM as a special case. In this paper, we provide a simple proof for the same convergence rate of the relaxed PPA in both ergodic and nonergodic senses.

1. Introduction

The finite-dimensional variational inequality (VI), denoted by $\text{VI}(\Omega, F)$, is to find a vector $w^* \in \Omega$ such that

$$
(w - w^*)^T F(w^*) \geq 0, \quad \forall w \in \Omega,
$$

where $\Omega$ is a nonempty closed convex set in $\mathbb{R}^n$ and $F$ is a monotone mapping from $\mathbb{R}^n$ into itself. The solution set, denoted by $\Omega^*$, is assumed to be nonempty. We refer to [1–4] for the pivotal roles of VIs in various fields such as economics, transportation, and engineering.

As is well known, proximal point algorithm (PPA), which was presented originally in [5] and mainly developed in [6, 7], is a well-developed approach to solving $\text{VI}(\Omega, F)$. Let $w^k$ be the current approximation of a solution of (1); then PPA generates the new iterate $w^{k+1} \in \Omega$ by solving the following auxiliary VI:

$$
(w - w^{k+1})^T F(w^{k+1}) + \frac{1}{\beta} (w^{k+1} - w^k) \geq 0,
$$

where $\beta$ is a positive constant. Compared to the monotone VI (1), (2) is easier to handle since it is a strongly monotone VI. In this paper, we focus on the relaxed proximal point algorithm (PPA) proposed by Gol’shtein and Tretyakov in [8], which combines the PPA step (3a) with a relaxation step (3b) as follows:

$$
\bar{w}^k \in \Omega, \quad (w - \bar{w}^k)^T [F(\bar{w}^k) + G(\bar{w}^k - w^k)] \geq 0, \quad \forall w \in \Omega,
$$

$$
w^{k+1} := w^k - \gamma (w^k - \bar{w}^k),
$$

where $\gamma \in (0, 2)$ is a relaxation factor and $G$ is a symmetric positive semidefinite matrix. In particular, $\gamma$ is called an under-relaxation factor when $\gamma \in (0, 1)$ or an over-relaxation factor when $\gamma \in (1, 2)$, and the relaxed PPA reduces to the original PPA (2) when $\gamma = 1$ and $G = (1/\beta)I$. For convenience, we still use the notation $\|w\|^2_G$ to represent the nonnegative number $w^T G w$ in our analysis.

The Douglas-Rachford alternating direction methods of multipliers (ADMM) scheme proposed by Glowinski and Marrocco in [9] (see also [10]) is a commonplace tool to solve the convex minimization problem with linear constraints and a separable objective function as follows:

$$
\min \{\theta_1(x) + \theta_2(y) \mid Ax + By = b, \ x \in \mathcal{X}, \ y \in \mathcal{Y}\},
$$

where $A \in \mathbb{R}^{m \times n_1}$, $B \in \mathbb{R}^{m \times n_2}$, $b \in \mathbb{R}^m$, $\mathcal{X} \subseteq \mathbb{R}^{n_1}$, and $\mathcal{Y} \subseteq \mathbb{R}^{n_2}$ are closed convex sets and $\theta_1: \mathbb{R}^{n_1} \rightarrow \mathbb{R}$ and
\[ \theta_2 : \mathbb{R}^n \rightarrow \mathbb{R} \] are convex smooth functions. The iterative scheme of ADMM for solving (4) at the \( k \)-th iteration runs as
\[
\begin{align*}
x^{k+1} & \in \mathcal{X}, \\
(x - x^{k+1})^T \{ \nabla \theta_1 (x^{k+1}) \\
& - A^T \left[ \lambda^k - H (Ax^{k+1} + By^k - b) \right] \} \geq 0, \\
\forall x \in \mathcal{X},
\end{align*}
\]
(5a)
\[
\begin{align*}
y^{k+1} & \in \mathcal{Y}, \\
(y - y^{k+1})^T \{ \nabla \theta_2 (y^{k+1}) \\
& - B^T \left[ \lambda^k - H (Ax^{k+1} + By^k - b) \right] \} \geq 0, \\
\forall y \in \mathcal{Y},
\end{align*}
\]
(5b)
\[
\begin{align*}
\lambda^{k+1} & := \lambda^k - H (Ax^{k+1} + By^k - b),
\end{align*}
\]
(5c)
where \( H := hI \) and \( h \) is a positive constant. As shown in [11], ADMM can be regarded as an application of the relaxed PPA with \( \gamma = 1 \) (i.e., the original PPA (2)) and
\[
G = \begin{pmatrix} 0 & 0 & 0 \\
0 & B^T HB & -B^T \\
0 & -B & H^{-1} \end{pmatrix}.
\]
(6)
Without further assumption on \( B \), the matrix \( G \) defined previously can be guaranteed as a symmetric and positive semidefinite matrix. Recently, He and Yuan in [12] have shown a worst-case \( O(1/t) \) convergence rate of the ADMM scheme (5a), (5b), and (5c) in an ergodic sense. You et al. in [13] have proved the same convergence rate of the Lagrangian PPA-based contraction methods with nonsymmetric linear proximal term in an ergodic sense. The purpose of this paper is to establish the \( O(1/t) \) convergence rate of the relaxed PPA (3a) and (3b) in both ergodic and nonergodic senses.

2. Preliminaries

In this section, we review some preliminaries which are useful for further discussions. More specially, we recall a useful characterization on \( \Omega^* \), the variational reformulation of (4), the relationship of the ADMM in [9, 10], and the relaxed PPA in [8] for solving this variational reformulation.

First, we provide a useful characterization on \( \Omega^* \) as Theorem 2.3.5 in [14] and Theorem 2.1 in [12].

**Theorem 1.** The solution set of \( \text{VI}(\Omega, F) \) is convex, and it can be characterized as
\[
\Omega^* = \bigcap_{w \in \Omega} \{ \bar{w} \in \Omega : (w - \bar{w})^T F(w) \geq 0 \}.
\]
(7)

Based on Theorem 1, \( \bar{w} \in \Omega \) can be regarded as an \( \varepsilon \)-approximation solution of \( \text{VI}(\Omega, F) \) if it satisfies
\[
\sup_{w \in \Omega} \{ (\bar{w} - w)^T F(w) \} \leq \varepsilon,
\]
where \( \Omega \subseteq \Omega \) is some compact set. As Definition 1 in [15], we can take
\[
\Omega = \Omega_{\Omega} (\bar{w}) := \{ w \in \Omega \mid \|w - \bar{w}\| \leq 1 \}.
\]
(9)

In the following, we will give a variational reformulation of (4). It is easy to see that the model (4) can be characterized by a variational inequality problem: find \( w^* = (x^*, y^*, \lambda^*) \in \Omega = \mathcal{X} \times \mathcal{Y} \times \mathbb{R}^m \) such that
\[
\text{VI}(\Omega, F) : (w - w^*)^T F(w^*) \geq 0, \quad \forall w \in \Omega,
\]
(10a)
where
\[
F(w) = \begin{pmatrix} \nabla \theta_1(x) - A^T \lambda \\
\nabla \theta_2(y) - B^T \lambda \\
Ax + By - b \end{pmatrix}.
\]
(10b)
Note that the mapping \( F \) is monotone since \( \theta_1 \) and \( \theta_2 \) are convex. As shown in [11], the ADMM scheme (5a), (5b), and (5c) is identical with the following iterative scheme in a cyclical sense:
\[
\begin{align*}
\bar{x}^k & \in \mathcal{X}, \quad (x - \bar{x}^k)^T \{ \nabla \theta_1 (\bar{x}^k) \\
& - A^T \left[ \lambda^k - H (A\bar{x}^k + By^k - b) \right] \} \geq 0, \\
\forall x \in \mathcal{X},
\end{align*}
\]
(11a)
\[
\lambda^k := \lambda^k - H (A\bar{x}^k + By^k - b),
\]
(11b)
\[
\bar{y}^k \in \mathcal{Y}, \quad (y - \bar{y}^k)^T \{ \nabla \theta_2 (\bar{y}^k) \\
& - B^T \left[ \lambda^k - H (A\bar{x}^k + By^k - b) \right] \} \geq 0, \\
\forall y \in \mathcal{Y},
\]
(11c)
\[
w^{k+1} = w^k - \left( w^k - \bar{w}^k \right).
\]
(12)
Based on the definition (6) of the matrix \( G \), we can rewrite (11a), (11b), (11c), and (12) as a special case of the relaxed PPA with \( \gamma = 1 \) immediately.

**Lemma 2.** For given \( w^k \), let \( \bar{w}^k \) be generated by the ADMM scheme (11a), (11b), and (11c). Then, one has
\[
\bar{w}^k \in \Omega, \quad (w - \bar{w}^k)^T \{ F(\bar{w}^k) + G(\bar{w}^k - w^k) \} \geq 0,
\]
(13)
\[
\forall w \in \Omega,
\]
where \( F \) and \( G \) are defined by (10b) and (6), respectively.
3. The Contraction of the Relaxed Proximal Point Algorithm

In this section, we prove the contraction of the relaxed PPA. First, we give an important lemma.

**Lemma 3.** Let the sequences \( \{w^k\} \) and \( \{\bar{w}^k\} \) be generated by the relaxed PPA (3a) and (3b), and let \( G \) be a symmetric positive semidefinite matrix. Then, one has

\[
(w - \bar{w}^k)^T F(\bar{w}^k) \geq \frac{1}{2\gamma} \left( \|w - w^{k+1}\|_G^2 - \|w - w^k\|_G^2 \right) + \left( 1 - \frac{\gamma}{2} \right) \|w^k - \bar{w}^k\|_G^2, \quad \forall w \in \Omega.
\]  

(14)

**Proof.** First, using (3a), we have

\[
(w - \bar{w}^k)^T G (w - \bar{w}^k) \geq \frac{1}{2\gamma} \left( \|w - w^{k+1}\|_G^2 - \|w - w^k\|_G^2 \right), \quad \forall w \in \Omega.
\]  

(15)

Since \( w^k - \bar{w}^k = (w^k - w^{k+1})/\gamma \) (see (3b)), we have

\[
(w - \bar{w}^k)^T G (w^k - \bar{w}^k) = \frac{1}{\gamma} (w - \bar{w}^k)^T G (w^k - w^{k+1}).
\]  

(16)

Thus, it suffices to show that

\[
(w - \bar{w}^k)^T G (w^k - w^{k+1}) \geq \frac{1}{2} \left( \|w - w^{k+1}\|_G^2 - \|w - w^k\|_G^2 \right) + \gamma \left( 1 - \frac{\gamma}{2} \right) \|w^k - \bar{w}^k\|_G^2.
\]  

(17)

By setting \( a = w, b = \bar{w}^k, c = w^k, \) and \( d = w^{k+1} \) in the identity

\[
(a - b)^T G (c - d) = \frac{1}{2} \left( \|a - d\|_G^2 - \|a - c\|_G^2 \right) + \frac{1}{2} \left( \|c - b\|_G^2 - \|d - b\|_G^2 \right),
\]  

(18)

we derive that

\[
(w - \bar{w}^k)^T G (w^k - w^{k+1}) \geq \frac{1}{2} \left( \|w - w^{k+1}\|_G^2 - \|w - w^k\|_G^2 \right) + \frac{1}{2} \left( \|w^k - \bar{w}^k\|_G^2 - \|w^{k+1} - \bar{w}^k\|_G^2 \right).
\]  

(19)

On the other hand, using (3b), we have

\[
\|w^k - \bar{w}^k\|_G^2 - \|w^{k+1} - \bar{w}^k\|_G^2 \leq \gamma (2 - \gamma) \|w^k - w^*\|_G^2.
\]  

(20)

Combining the last two equations, we obtain (17). The assertion (14) follows immediately. The proof is completed.

With the proved lemma, we are now ready to show the contraction of the relaxed PPA (3a) and (3b).

**Theorem 4.** Let the sequences \( \{w^k\} \) and \( \{\bar{w}^k\} \) be generated by the relaxed PPA (3a) and (3b), and let \( G \) be a symmetric positive semidefinite matrix. Then, for any \( k \geq 0 \), one has

\[
\|w^k - w^*\|_G^2 \leq \|w^k - w^*\|_G^2 - \gamma (2 - \gamma) \|w^k - w^*\|_G^2.
\]  

(21)

**Proof.** Setting \( w = w^* \) in (14), we get

\[
2\gamma (w^* - \bar{w}^k)^T F(\bar{w}^k) \geq \|w^* - w^k\|_G^2 - \|w^* - w^k\|_G^2 \geq \gamma (2 - \gamma) \|w^k - \bar{w}^k\|_G^2.
\]  

(22)

On the other hand, since \( F \) is monotone and \( w^* \in \Omega^* \), we have

\[
0 \geq (w^* - \bar{w}^k)^T F(\bar{w}) \geq (w^* - \bar{w}^k)^T F(\bar{w}^k).
\]  

(23)

It follows from the previous two inequalities that

\[
\|w^{k+1} - w^*\|_G^2 \leq \|w^k - w^*\|_G^2 - \gamma (2 - \gamma) \|w^k - \bar{w}^k\|_G^2.
\]  

(24)

The proof is completed.

4. Ergodic Worst-Case \( O(1/t) \) Convergence Rate

In this section, we will establish an ergodic worst-case \( O(1/t) \) convergence rate for the relaxed PPA in the sense that after \( t \) iterations of such an algorithm, we can find \( \bar{w} \in \Omega \) such that

\[
(\bar{w} - w)^T F(w) \leq \varepsilon, \quad \forall w \in B_{\Omega} (\bar{w}),
\]  

(25)

with \( \varepsilon = O(1/t) \) and \( B_{\Omega} (\bar{w}) := \{w \in \Omega | \|w - \bar{w}\|_G \leq 1\} \).
**Theorem 5.** Let \( \{w^k\} \) and \( \{\tilde{w}^k\} \) be the sequences generated by the relaxed PPA (3a) and (3b), and let \( G \) be a symmetric positive semidefinite matrix. For any integer number \( t > 0 \), let

\[
\tilde{w}_i := \frac{1}{t+1} \sum_{k=0}^{t} \tilde{w}^k.
\]

Then, one has \( \tilde{w}_i \in \Omega \) and

\[
(\tilde{w}_i - w)^T F(w) \leq \frac{1}{2y(t+1)} \|w^0 - w\|^2_G, \quad \forall w \in \Omega. \tag{27}
\]

**Proof.** From (14), we have

\[
(w - \tilde{w}^k)^T F(w) + \frac{1}{2y} \|w^k - w\|^2_G
\geq \frac{1}{2y} \|w^{k+1} - w\|^2_G, \quad \forall w \in \Omega.
\]

Since \( F \) is monotone, from the previous inequality, we have

\[
(w - \tilde{w})^T F(w) + \frac{1}{2y} \|w^k - w\|^2_G
\geq \frac{1}{2y} \|w^{k+1} - w\|^2_G, \quad \forall w \in \Omega.
\]

Summing the inequality (29) over \( k = 0, 1, \ldots, t \), we obtain

\[
\left[ (t + 1) w - \left( \sum_{k=0}^{t} \tilde{w}^k \right) \right]^T F(w) + \frac{1}{2y} \|w^0 - w\|^2_G
\geq \frac{1}{2y} \|w^{k+1} - w\|^2_G \geq 0, \quad \forall w \in \Omega.
\]

Since \( \sum_{k=0}^{t} \frac{1}{t+1} = 1 \), \( \tilde{w}_i \) is a convex combination of \( \tilde{w}^0, \tilde{w}^1, \ldots, \tilde{w}^t \) and thus \( \tilde{w}_i \in \Omega \). Using the notation of \( \tilde{w}_i \), we derive

\[
(w - \tilde{w}_i)^T F(w) + \frac{1}{2y} \|w^0 - w\|^2_G \geq 0, \quad \forall w \in \Omega.
\]

The assertion (27) follows from the previous inequality immediately. \( \square \)

Recall that \( \tilde{w}_i \) is the average of \( \{\tilde{w}^0, \tilde{w}^1, \ldots, \tilde{w}^t\} \). Thus, we have \( \|\tilde{w}_i\|_G \leq D \). For any \( w \in \mathcal{B}_\Omega(\tilde{w}_i) := \{w \in \Omega \mid \|w - \tilde{w}_i\|_G \leq 1\} \), we get

\[
(\tilde{w}_i - w)^T F(w)
\leq \frac{1}{2y(t+1)} \|w^0 - w\|^2_G
\leq \frac{1}{2y(t+1)} \left( \|w^0 - \tilde{w}_i\|_G + \|\tilde{w}_i - w\|_G \right)^2
\leq \left( 2D + 1 \right)^2 \frac{1}{2y(t+1)}.
\]

Thus, for any given \( \varepsilon > 0 \), after at most \( t := \lceil (2D+1)^2/2y\varepsilon \rceil - 1 \) iterations, we have

\[
(\tilde{w}_i - w)^T F(w) \leq \varepsilon, \quad \forall w \in \mathcal{B}_\Omega(\tilde{w}_i),
\]

which means that \( \tilde{w}_i \) is an approximate solution of \( VI(\Omega, F) \) with an accuracy of \( O(1/t) \). That is, a worst-case \( O(1/t) \) convergence rate of the relaxed PPA in an ergodic sense is established.

Note that this convergence rate is in an ergodic sense and \( \tilde{w}_i \) is a convex combination of the previous vectors \( \{\tilde{w}^0, \tilde{w}^1, \ldots, \tilde{w}^t\} \) with equal weights. One may ask if we can establish the same convergence rate in a nonergodic sense directly for the sequence \( \{w^k\} \) generated by the relaxed PPA (3a) and (3b), and this is the main purpose of the next section.

**5. Nonergodic Worst-Case \( O(1/t) \) Convergence Rate**

This section shows that the relaxed PPA has a worst-case \( O(1/t) \) convergence rate in a nonergodic sense. First, we establish two important inequalities in the following lemmas.

**Lemma 6.** Let the sequences \( \{w^k\} \) and \( \{\tilde{w}^k\} \) be generated by the relaxed PPA (3a) and (3b), and let \( G \) be a symmetric positive semidefinite matrix. Then, one has

\[
(\tilde{w}^k - w^{k+1})^T G [(w^k - w^{k+1}) - (\tilde{w}^k - w^{k+1})] \geq 0. \tag{35}
\]

**Proof.** Setting \( w = \tilde{w}^{k+1} \) in (3a), we have

\[
(\tilde{w}^{k+1} - w)^T F(w^k) + G(\tilde{w}^k - w) \geq 0. \tag{36}
\]

Note that (3a) is also true for \( k := k + 1 \), and thus we have

\[
(w - \tilde{w}^{k+1})^T F(\tilde{w}^{k+1}) + G(\tilde{w}^{k+1} - w) \geq 0, \quad \forall w \in \Omega. \tag{37}
\]
Setting \( w = \bar{w}^k \) in the previous inequality, we obtain
\[
(\bar{w}^k - \bar{w}^{k+1})^T F(\bar{w}^{k+1}) + G(\bar{w}^{k+1} - w^{k+1}) \geq 0. \tag{38}
\]
Adding (36) and (38) and using the monotonicity of \( F \), we get (35) immediately.

**Lemma 7.** Let the sequences \( \{w^k\} \) and \( \{\bar{w}^k\} \) be generated by the relaxed PPA (3a) and (3b), and let \( G \) be a symmetric positive semidefinite matrix. Then, one has
\[
(\bar{w}^k - \bar{w}^{k+1})^T G \left\{ \left( (w^k - \bar{w}^k) - (w^{k+1} - \bar{w}^{k+1}) \right) \right\} \geq \frac{1}{\gamma} \left\| (w^k - \bar{w}^k) - (w^{k+1} - \bar{w}^{k+1}) \right\|^2_G. \tag{39}
\]

**Proof.** First, adding the term
\[
\left\{ (w^k - w^{k+1}) - (\bar{w}^k - \bar{w}^{k+1}) \right\}^T G \left\{ (w^k - \bar{w}^k) - (w^{k+1} - \bar{w}^{k+1}) \right\}
\]
to the both sides of (35), we get
\[
(\bar{w}^k - \bar{w}^{k+1})^T G \left\{ \left( (w^k - \bar{w}^k) - (w^{k+1} - \bar{w}^{k+1}) \right) \right\} \geq \left\| (w^k - \bar{w}^k) - (w^{k+1} - \bar{w}^{k+1}) \right\|^2_G. \tag{40}
\]
Reordering \( (w^k - w^{k+1}) - (\bar{w}^k - \bar{w}^{k+1}) \) in the previous inequality to \( (w^k - \bar{w}^k) - (w^{k+1} - \bar{w}^{k+1}) \), we get
\[
(\bar{w}^k - \bar{w}^{k+1})^T G \left\{ \left( (w^k - \bar{w}^k) - (w^{k+1} - \bar{w}^{k+1}) \right) \right\} \geq \left\| (w^k - \bar{w}^k) - (w^{k+1} - \bar{w}^{k+1}) \right\|^2_G. \tag{41}
\]
Substituting the term \( w^k - w^{k+1} = \gamma (w^k - \bar{w}^k) \) (see (3b)) into the left-hand side of the last inequality, we obtain (39). The proof is completed.

Next, we prove that \( \| w^k - \bar{w}^k \|_G \) is monotonically non-increasing.

**Theorem 8.** Let the sequences \( \{w^k\} \) and \( \{\bar{w}^k\} \) be generated by the relaxed PPA (3a) and (3b), and let \( G \) be a symmetric positive semidefinite matrix. Then, one has
\[
\| w^{k+1} - \bar{w}^{k+1} \|_G \leq \| w^k - \bar{w}^k \|_G, \quad \forall k \geq 0. \tag{43}
\]

**Proof.** Setting \( a = w^k - \bar{w}^k \) and \( b = w^{k+1} - \bar{w}^{k+1} \) in the identity
\[
\| a \|_G^2 - \| b \|_G^2 = 2 a^T G (a - b) - \| a - b \|_G^2, \tag{44}
\]
we obtain
\[
\| w^k - \bar{w}^k \|_G^2 - \| w^{k+1} - \bar{w}^{k+1} \|_G^2 = 2 (w^k - \bar{w}^k)^T G \left\{ \left( (w^k - \bar{w}^k) - (w^{k+1} - \bar{w}^{k+1}) \right) \right\} \geq \gamma (2 - \gamma) \| w^k - \bar{w}^k \|_G^2. \tag{45}
\]
Inserting (39) into the first term of the right-hand side of the last equality and using \( \gamma \in (0, 2) \), we obtain
\[
2 (w^k - \bar{w}^k)^T G \left\{ \left( (w^k - \bar{w}^k) - (w^{k+1} - \bar{w}^{k+1}) \right) \right\} \geq \frac{2 - \gamma}{\gamma} \| w^k - \bar{w}^k \|_G^2 \geq 0. \tag{46}
\]
The assertion (43) follows immediately.

With Theorems 4 and 8, we can prove the worst-case \( O(1/t) \) convergence rate in a nonergodic sense for the relaxed PPA.

**Theorem 9.** Let the sequences \( \{w^k\} \) and \( \{\bar{w}^k\} \) be generated by the relaxed PPA (3a) and (3b), and let \( G \) be a symmetric positive semidefinite matrix. Then, for any integer \( t \geq 0 \), one has
\[
\| w^t - \bar{w}^t \|_G \leq \frac{1}{\gamma (2 - \gamma)} \| w^0 - w^* \|_G^2, \quad \forall w^* \in \Omega^*. \tag{47}
\]

**Proof.** Summing the inequality (21) over \( k = 0, 1, \ldots, t \), we obtain
\[
\gamma (2 - \gamma) \sum_{k=0}^{t} \| w^k - \bar{w}^k \|_G^2 \leq \sum_{k=0}^{t} \| w^k - \bar{w}^k \|_G^2 \leq \| w^0 - w^* \|_G^2 \tag{48}
\]
According to Theorem 8, the sequence \( \{\| w^k - \bar{w}^k \|_G \} \) is monotonically nonincreasing. Therefore, we have
\[
(t + 1) \| w^t - \bar{w}^t \|_G \leq \| w^0 - w^* \|_G^2, \quad \forall w^* \in \Omega^*. \tag{49}
\]
The assertion (47) follows from (48) and (49) immediately.

Note that \( \Omega^* \) is convex and closed (see Theorem 1). Let \( d := \inf \{ \| w^0 - w^* \|_G \mid w^* \in \Omega^* \} \). Then, for any given \( \varepsilon > 0 \), Theorem 9 shows that the relaxed PPA (3a) and (3b) needs at most \( d^2 / (\varepsilon (2 - \gamma)) - 1 \) iterations to ensure that \( \| w^t - \bar{w}^t \|_G \leq \varepsilon \). Recall that \( \bar{w}^t \) is a solution of \( V(\Omega, F) \) if \( \| w^t - \bar{w}^t \|_G^2 = 0 \). In other words, if \( \| w^t - \bar{w}^t \|_G^2 = 0 \), we have \( G(\bar{w}^t) = 0 \) since \( G \) is a positive semidefinite matrix. And thus from (3a), it follows that
\[
(\bar{w}^t)^T \bar{F}(\bar{w}^t) \geq 0, \quad \forall w \in \Omega, \tag{50}
\]
which means that \( \bar{w}^t \) is a solution of \( V(\Omega, F) \) according to (1). A worst-case \( O(1/t) \) convergence rate in a nonergodic sense for the relaxed PPA (3a) and (3b) is thus established from Theorem 9.
6. Concluding Remarks

This paper established the worst-case $O(1/t)$ convergence rate in both ergodic and nonergodic senses for the relaxed PPA. Recall that ADMM is a primal application of the relaxed PPA with $\gamma = 1$. And thus ADMM also has the same worst-case $O(1/t)$ convergence rate in both ergodic and nonergodic senses.
