Abstract

A nonlocal gravity model was introduced and considered recently, and two exact cosmological solutions in flat space were presented. The first solution is related to some radiation effects generated by nonlocal dynamics on dark energy background, while the second one is a nonsingular time symmetric bounce. In the present paper we investigate other possible exact cosmological solutions and find some new ones in nonflat space. Used nonlocal gravity dynamics can change background topology. To solve the corresponding equations of motion, we first look for a solution of the eigenvalue problem \( \Box (R - 4\Lambda) = q (R - 4\Lambda) \).

1 Introduction

The current Standard Model of Cosmology (SMC) [1], also known as ΛCDM model, assumes General Relativity (GR) [2] as theory of the gravitational interaction at all cosmic spacetime scales – galactic and cosmological. According to this model, at current cosmic time the universe approximately contains 68% of dark energy (DE), 27% of dark matter (DM) and 5% of visible matter. By ΛCDM model, dark matter is responsible for observational dynamics inside and between galaxies, while dark energy causes accelerated expansion of the universe. ΛCDM model also asserts that DE corresponds to the cosmological constant and that DM is in a cold state. In the last few decades many efforts were done to confirm existence of DM and DE in the sky or in the laboratory experiments, but they are not discovered, and their existence still remains hypothetical. A brief review of recent investigations of DM and DE is presented in [3].

Due to its significant phenomenological achievements and beautiful theoretical properties, GR is considered as one of the basic modern physical theories [4]. For example, GR describes dynamics of the Solar system very well. Many important phenomena were also predicted and observationally confirmed: deflection of light near the Sun, black holes, as well as gravitational light redshift, lensing, and waves. However, GR as a theory of gravitation has not been verified at the galactic and cosmological scales. Despite remarkable successes, GR solutions for the black holes and the beginning of the universe contain singularities. In addition, from quantization point of view, GR is a nonrenormalizable theory. Note also that every other physical theory has its domain of validity which is usually constrained by spacetime scale, complexity of the system under consideration, or by some parameters. There is
no a priori reason that GR is an exception and should be theory of gravitation from the
Planck scale to the universe as a whole. Taking into account all these remarks it follows that
general relativity is not a final gravitational theory and that investigation of its extension is
needed, e.g., see [5] [6] [7] [8] [9] [10] [11] [12] and references therein.

Since it is not invented so far a new physical principle that could say in which direction
extend GR, there are many approaches to its modification (for a review, see [5] [6] [7] [8] [9]).
One of the current and attractive approaches to general relativity modification is its nonlocal
extension, see e.g. [13] [14] [15] [16] [17] [18] [19] [20] [21] [22] and [23] [24] [25] [26] [27] [30] [31] [32] [33].

The idea behind nonlocality is that dynamics of the gravitational field may depend not only
on its first and second space-time derivative but also on all higher derivatives. It means
that the Einstein-Hilbert action should be extended by an additional nonlocal term that
contains the d’Alembert-Beltrami operator □ which is mainly employed in two ways: (i)
using an analytic expansion $F(□) = \sum_{n=0}^{\infty} f_n □^n$, or (ii) including in some manner operator
□$^{-1}$ [13] [14] [15] [34], and its higher powers.

The modification of type (i) comes from ordinary and $p$-adic string theory, see [35]
and references therein. This type of nonlocality improves quantum renormalizability [36] [37] [38].
Nonlocal gravity models of type (i) that have attracted much attention are given by action

$$ S = \frac{1}{16\pi G} \int_M \sqrt{-g} \left( R - 2\Lambda + P(R) F(□) Q(R) \right) d^4x, \quad (1.1) $$

where $M$ is a four-dimensional pseudo-Riemannian manifold of signature $(-,+,+,+)$ with
metric $(g_{\mu\nu})$, $P(R)$ and $Q(R)$ are some differentiable functions of scalar curvature $R$, $\Lambda$
is the cosmological constant, and $F(□) = \sum_{n=0}^{\infty} f_n □^n$. To better see effects of nonlocal
modification of GR in its geometrical sector, action (1.1) intentionally does not contain
matter term. Derivation of equations of motion that are related to nonlocal gravity (1.1) is
a difficult task, and for details we refer to our paper [39], see also [20].

Action (1.1) is rather general and contains several simple nonlocal extensions of GR.
$P(R) = Q(R) = R$ is a case that has attracted the most attention, see [16] [17] [24] [25]
and [10] [11] [12] [13] [18] [19] [20] [21]. This kind of nonlocal investigation started in [16] [17] and is
an attempt to find nonsingular bouncing solution of the singularity problem in standard
cosmology. It is worth mentioning an interesting model when $P(R) = Q(R) = \sqrt{R - 2\Lambda}$,
which contains cosmological solution $a(t) = At^{\frac{2}{3}} e^{\frac{\Lambda^2}{2}}$ that mimics an interference between
dark matter ($\dot{\phi}$) and dark energy ($e^{\frac{\Lambda^2}{2}}$), $\Lambda > 0$ in flat space ($k = 0$). Explored cosmological
parameters are in good agreement with $Λ$CDM data, see [48].

This paper is devoted to the further investigation of the nonlocal gravity model which is
given by $P(R) = Q(R) = R - 4\Lambda$, and presented in [19]. The nonlocal term $(R - 4\Lambda) F(□)$
may appear as a generalization of $R F(□)$, $R$. This model is also of interest
as the limit case of model $P(R) = Q(R) = \sqrt{R - 2\Lambda}$ for $|R| \ll |2\Lambda|$, see Section 2. In the
paper [19] we investigated the exact cosmological solutions for $\Lambda \neq 0$, $k = 0$: $a_1(t) =
A\sqrt{7} e^{\frac{\Lambda^2}{2}}$, and $a_2(t) = Ae^{\Lambda^2}$. The first solution mimics an interplay between dark energy
and radiation. The second solution is a nonsingular bounce one and an even function of
cosmic time. In this paper we consider new cosmological solutions with scale factors of the
two forms: $a(t) = \left(\alpha e^{\lambda t} + \beta e^{-\lambda t}\right)^{\gamma}$ and $a(t) = \left(\alpha \cos \lambda t + \beta \sin \lambda t\right)^{\gamma}$, where $\gamma$ is an arbitrary
real parameter.

The paper is organized as follows. In Section 2, the concrete nonlocal gravity model is set
up and some general properties of the relevant equations of motion are presented. Section 3
contains consideration of various aspects of the corresponding cosmological solutions: brief
review of two previous results, relevant eigenvalue problem and detailed analysis related to finding of the new exact cosmological solutions. Discussion and conclusions are presented in Section 4.

2 Gravity Model with Additional Nonlocal Term

\[(R - 4\Lambda) \mathcal{F}(\Box) (R - 4\Lambda)\]

Nonlocal gravity model under consideration is given by action

\[
S = \frac{1}{16\pi G} \int d^4x \sqrt{-g} \left( R - 2\Lambda + (R - 4\Lambda) \mathcal{F}(\Box) (R - 4\Lambda) \right),
\]

(2.1)

where \(\Box = \nabla_\mu \nabla^\mu = \frac{1}{\sqrt{-g}} \partial_\mu (\sqrt{-g} g^{\mu\nu} \partial_\nu)\) is the d'Alembert-Beltrami operator on the corresponding gravity background and \(\mathcal{F}(\Box) = \sum_{n=1}^{+\infty} f_n \Box^n\) is nonlocal operator with all higher order space-time derivatives. Formally, (2.1) gets from (1.1) taking \(P(R) = Q(R) = R - 4\Lambda\) and \(f_0 = 0\). However, (2.1) can be also derived from action

\[
S = \frac{1}{16\pi G} \int d^4x \sqrt{-g} \left( R - 2\Lambda + \sqrt{R - 2\Lambda} \mathcal{F}(\Box) \sqrt{R - 2\Lambda} \right)
\]

(2.2)

which also belongs to the class of nonlocal models (1.1). In fact, let us start from action (2.2) and consider expansion of \(\sqrt{R - 2\Lambda} = \sqrt{-2\Lambda} \sqrt{1 - \frac{R}{2\Lambda}}\) in powers of \(\frac{R}{2\Lambda}\), where \(|R| \ll |2\Lambda|\). Then let us take approximation linear in \(\frac{R}{2\Lambda}\), i.e. one obtains \(\sqrt{R - 2\Lambda} \approx \sqrt{-2\Lambda} (1 - \frac{R}{4\Lambda})\). By this way, nonlocal term in (2.2) becomes

\[
\sqrt{R - 2\Lambda} \mathcal{F}(\Box) \sqrt{R - 2\Lambda} \approx -\frac{1}{8\Lambda} (R - 4\Lambda) \mathcal{F}(\Box) (R - 4\Lambda),
\]

(2.3)

where factor \(-\frac{1}{8\Lambda}\) can be included in nonlocal operator \(\mathcal{F}(\Box)\) by its redefinition. At the same time, the first term \(R - 2\Lambda = \sqrt{R - 2\Lambda} \sqrt{R - 2\Lambda}\) remains unchanged in the linear approximation.

As it is already mentioned in Introduction, nonlocal gravity model (2.2) is very interesting and promising. It is natural nonlocal generalization of the de Sitter model

\[
S_0 = \frac{1}{16\pi G} \int d^4x \sqrt{-g} (R - 2\Lambda),
\]

(2.4)

where generalization obtains in the following way:

\[
R - 2\Lambda = \sqrt{R - 2\Lambda} \sqrt{R - 2\Lambda} \to \sqrt{R - 2\Lambda} \mathcal{F}(\Box) \sqrt{R - 2\Lambda}.
\]

(2.5)

Nonlocal operator \(F(\Box)\) in (2.5) is \(F(\Box) = 1 + \mathcal{F}(\Box) = 1 + \sum_{n=1}^{+\infty} f_n \Box^n\). Nonlocal de Sitter model (also called nonlocal square root gravity [48]) (2.2) contains two exact scale factors:

\[
a(t) = A t^k e^{\frac{\Lambda}{2} t^2}, \quad a(t) = A e^{\frac{\Lambda}{2} t^2}, \quad k = 0.
\]

(2.6)

The first solution in (2.6) mimics an interference between dark matter expansion \((t^k)\) and dark energy acceleration \((e^{\frac{\Lambda}{2} t^2}, \Lambda > 0)\) in flat space \((k = 0)\), and calculated cosmological quantities are in good agreement with standard model of cosmology, see details in [48]. The second solution in (2.6) is an example of nonsingular bounce at cosmic time \(t = 0\).
2.1 Equations of Motion

The next step in investigation of nonlocal gravity model (2.1) is finding the corresponding equations of motion (EOM). It is done for a class of models (1.1), that contains (2.1), and derivation is presented in [39].

According to [39], the EOM for nonlocal gravity model (1.1) have the following form:

\[ \hat{G}_{\mu\nu} = G_{\mu\nu} + \Lambda g_{\mu\nu} - \frac{1}{2} g_{\mu\nu} P(R) \mathcal{F}(\Box) Q(R) + R_{\mu\nu} W - K_{\mu\nu} W + \frac{1}{2} \Omega_{\mu\nu} = 0, \]

(2.7)

where

\[ W = P'(R) \mathcal{F}(\Box) Q(R) + \mathcal{Q}'(R) \mathcal{F}(\Box) P(R), \quad K_{\mu\nu} = \nabla_\mu \nabla_\nu - g_{\mu\nu} \Box, \]

(2.8)

\[ \Omega_{\mu\nu} = \sum_{n=1}^{+\infty} f_n \sum_{\ell=0}^{n-1} S_{\mu\nu}(\Box^\ell P(R), \Box^{n-1-\ell} Q(R)), \]

(2.9)

and \( P', \mathcal{Q}' \) denote derivative of \( P, \mathcal{Q} \) with respect to \( R \).

It is clear that EOM (2.7) are very complicated comparing them to the local (Einstein) counterpart \( G_{\mu\nu} + \Lambda g_{\mu\nu} = 0 \). Finding any solutions of (2.7) is not an easy task. However, in the sequel of this article we will see how one can find some exact cosmological solutions when \( P(R) = Q(R) = R - 4\Lambda \), i.e. in the nonlocal gravity model (2.1).

First, let us consider the case when \( Q(R) = P(R) \). Then EOM (2.7) reduce to:

\[ G_{\mu\nu} + \Lambda g_{\mu\nu} - \frac{g_{\mu\nu}}{2} P(R) \mathcal{F}(\Box) P(R) + R_{\mu\nu} W - K_{\mu\nu} W + \frac{1}{2} \Omega_{\mu\nu} = 0, \]

(2.11)

\[ W = 2P'(R) \mathcal{F}(\Box) P(R), \quad K_{\mu\nu} = \nabla_\mu \nabla_\nu - g_{\mu\nu} \Box, \]

(2.12)

\[ \Omega_{\mu\nu} = \sum_{n=1}^{+\infty} f_n \sum_{\ell=0}^{n-1} S_{\mu\nu}(\Box^\ell P, \Box^{n-1-\ell} P) \]

(2.13)

\[ S_{\mu\nu}(\Box^\ell P, \Box^{n-1-\ell} P) = \sum_{\ell=0}^{n-1} \left( g_{\mu\nu} \nabla_\alpha \Box^\ell P(R) \nabla_\beta \Box^{n-1-\ell} P(R) + \Box^\ell P(R) \Box^{n-\ell} P(R) \right) \]

\[ - 2 \nabla_\alpha \Box^\ell P(R) \nabla_\beta \Box^{n-1-\ell} P(R) \].

(2.14)

The further significant simplification of EOM can be obtained if \( P(R) \) is an eigenfunction of the corresponding d’Alembert-Beltrami operator \( \Box \), i.e. if holds

\[ \Box P(R) = q P(R), \quad \mathcal{F}(\Box) P(R) = \mathcal{F}(q) P(R), \]

(2.15)

where \( q = \zeta \Lambda \) (\( \zeta \) dimensionless parameter) is an eigenvalue. Note that parameter \( q \) must have the same dimensionality as \( \Box \), where dimension of \( \Box \) is \( T^{-2} \) in natural units (\( \hbar = c = 1 \)). Hence, \( q \) has to be proportional to \( \Lambda \), since there is only the cosmological constant \( \Lambda \) in the above EoM with dimension as \( \Box \). Moreover, \( q = \zeta \Lambda \) naturally appears in all concrete cases and there is no need for a new constant in this nonlocal gravity model without matter. Then

\[ W = 2 \mathcal{F}(q) P P', \quad \mathcal{F}(q) = \sum_{n=1}^{+\infty} f_n q^n, \]

(2.16)

\[ \Omega_{\mu\nu} = \mathcal{F}'(q) S_{\mu\nu}(P, P), \]

(2.17)

\[ G_{\mu\nu} + \Lambda g_{\mu\nu} + \mathcal{F}(q) \left( 2(R_{\mu\nu} - K_{\mu\nu}) PP' - \frac{g_{\mu\nu}}{2} P^2 \right) \]

\[ + \frac{1}{2} \mathcal{F}'(q) S_{\mu\nu}(P, P) = 0. \]

(2.18)
Both expressions in (2.16) are evident. Equality (2.17) obtains as follows:

\[ \Omega_{\mu\nu} = \sum_{n=1}^{\infty} f_n n^{n-1} S_{\mu\nu}(P, P) = \sum_{n=1}^{\infty} f_n n^{n-1} S_{\mu\nu}(P, P) \]  

(2.19)

\[ = \sum_{n=1}^{\infty} f_n n^{n-1} S_{\mu\nu}(P, P) = F'(q)S_{\mu\nu}(P, P). \]  

(2.20)

Finally, take \( P = R - 4\Lambda \). Then \( PP' = P = R - 4\Lambda \) and EOM become

\[ G_{\mu\nu} + \Lambda g_{\mu\nu} + F'(q) \left( G_{\mu\nu} + R_{\mu\nu} - 2\nabla_{\mu} \nabla_{\nu} + 2g_{\mu\nu}(\Lambda + q) \right) (R - 4\Lambda) \]

\[ + \frac{1}{2} F'(q)S_{\mu\nu}(R - 4\Lambda, R - 4\Lambda) = 0. \]  

(2.21)

In some cases there is solution when \( F'(q) = 0 \) and then problem (2.21) reduces to:

\[ F'(q) = 0, \quad \text{and} \]

\[ G_{\mu\nu} + \Lambda g_{\mu\nu} + F(q) \left( G_{\mu\nu} + R_{\mu\nu} - 2\nabla_{\mu} \nabla_{\nu} + 2g_{\mu\nu}(\Lambda + q) \right) (R - 4\Lambda) = 0. \]  

(2.22)

(2.23)

In finding cosmological solutions, we start from equations (2.21).

3 Cosmological Solutions

In this section we are mainly interested in finding and investigation of some new exact cosmological solutions of nonlocal gravity model (2.1).

Since the universe is homogeneous and isotropic at large cosmic scales, hence its evolution satisfies the Friedmann-Lemaître-Robertson-Walker (FLRW) metric

\[ ds^2 = -dt^2 + a^2(t) \left( \frac{dr^2}{1 - kr^2} + r^2 d\theta^2 + r^2 \sin^2 \theta d\phi^2 \right), \quad (c = 1), \quad k = 0, \pm 1, \]  

(3.1)

where \( a(t) \) is the cosmic scale factor that contains information on expansion (or contraction) and \( k \) is the constant curvature parameter.

The d’Alembert-Beltrami operator \( \square \), the Hubble parameter \( H \) and the Ricci scalar \( R \) for the FLRW metric are:

\[ \square = -\frac{\partial^2}{\partial t^2} - 3\frac{H(t)}{a} \frac{\partial}{\partial t}, \quad H(t) = \frac{\dot{a}}{a}, \]  

\[ R(t) = 6 \left( \frac{\ddot{a}}{a} + \left( \frac{\dot{a}}{a} \right)^2 + \frac{k}{a^2} \right), \quad \dot{a} = \frac{\partial a}{\partial t}. \]  

(3.2)

Since the universe is homogeneous and isotropic there are only two independent equations of motion (2.21). It is convenient to use the trace and 00-component of (2.21):

\[ (R - 4\Lambda) \left[ F'(\Lambda)(8 + 6\zeta)\Lambda - 1 \right] + \frac{1}{2} F'(\Lambda) S(R - 4\Lambda, R - 4\Lambda) = 0, \]  

(3.3)

\[ G_{00} - \Lambda + F'(\Lambda) \left( 2R_{00} + \frac{1}{2} R - 2\frac{k}{a^2} - 2(1 + \zeta)\Lambda \right) (R - 4\Lambda) \]

\[ + \frac{1}{2} F'(\Lambda) S_{00}(R - 4\Lambda, R - 4\Lambda) = 0, \]  

(3.4)
where \( S(R - 4\Lambda, R - 4\Lambda) = g^{\mu\nu} S_{\mu\nu}(R - 4\Lambda, R - 4\Lambda) \) and equality \( \Box(R - 4\Lambda) = q(R - 4\Lambda) = \zeta \Lambda(R - 4\Lambda) \) has been taken into account. According to (3.4) we have to use

\[
R_{00} = -3 \frac{\ddot{a}}{a}, \quad G_{00} = 3 \frac{\dot{a}^2 + k}{a^2}. \tag{3.5}
\]

Note that EOM (2.21) can be rewritten in the form of general relativity

\[
\hat{G}_{\mu\nu} = G_{\mu\nu} + \Lambda g_{\mu\nu} - 8\pi G \hat{T}_{\mu\nu} = 0, \quad \nabla^\mu \hat{G}_{\mu\nu} = 0, \tag{3.6}
\]

where \( \hat{T}_{\mu\nu} \) is the corresponding effective energy-momentum tensor. The related Friedmann equations to (3.6) are

\[
\ddot{a} = -\frac{4\pi G}{3} \left( \bar{\rho} + 3\bar{p} \right) + \frac{\Lambda}{3}, \quad \frac{\dot{a}^2 + k}{a^2} = \frac{8\pi G}{3} \bar{\rho} + \frac{\Lambda}{3}, \tag{3.7}
\]

where \( \bar{\rho} \) is an effective energy density and \( \bar{p} \) is an effective pressure of the universe. The corresponding equation of state is

\[
\bar{p}(t) = \bar{w}(t) \bar{\rho}(t), \tag{3.8}
\]

where \( \bar{w}(t) \) is a dimensionless parameter that may depend on time.

It is worth noting that the Minkowski space \((a(t) = \text{const.}, \quad R = \Lambda = k = 0)\) is also a solution of EOM (3.3) and (3.4).

### 3.1 Two Previous Exact Solutions

In order to have more complete insight into \( a(t) \) solutions of nonlocal model (2.1), we want first briefly review previously found two nontrivial solutions [49] and after that present new exact solutions.

We found the following exact cosmological solutions, \( \Lambda \neq 0, \quad k = 0 \):

\[
a_1(t) = A \ e^{\frac{\Box}{3} t^2}, \quad \Box(R - 4\Lambda) = -3\Lambda(R - 4\Lambda), \tag{3.9}
\]

\[
a_2(t) = A \ e^{\lambda t^2}, \quad \Box(R - 4\Lambda) = -12\Lambda(R - 4\Lambda). \tag{3.10}
\]

We explicitly found expression for \( R(t), \ H(t) \), solved the corresponding eigenvalue problems and EOM for both \( a_1(t) \) and \( a_2(t) \), and also found constraints on the nonlocal operator function \( \mathcal{F}() \):

\[
(a_1): \quad \mathcal{F}(-3\Lambda) = -\frac{1}{10\Lambda}, \quad \mathcal{F}'(-3\Lambda) = 0, \quad \Lambda \neq 0, \tag{3.11}
\]

\[
(a_2): \quad \mathcal{F}(-12\Lambda) = -\frac{1}{64\Lambda}, \quad \mathcal{F}'(-12\Lambda) = 0, \quad \Lambda \neq 0, \tag{3.12}
\]

that are simply satisfied by

\[
(a_1): \quad \mathcal{F}(\Box) = \frac{\Box}{30\Lambda^2} \exp\left(\frac{\Box}{3\Lambda} + 1\right), \tag{3.13}
\]

\[
(a_2): \quad \mathcal{F}(\Box) = \frac{\Box}{768\Lambda^2} \exp\left(\frac{\Box}{12\Lambda} + 1\right), \tag{3.14}
\]

respectively.
The solution of the effective Friedmann equations were also found in both cases, and consequently the equations of state are:

\[ (a_1) : \ \bar{w} = \frac{\bar{\rho}(t)}{\bar{\rho}(t)} = \begin{cases} -1, & t \to \infty \\ \frac{1}{3}, & t \to 0. \end{cases} \]  
\[ (a_2) : \ \bar{w} = \frac{-12\Lambda t^2 - 3}{12\Lambda t^2 - 1} \rightarrow \begin{cases} -1, & t \to \infty \\ 3, & t \to 0. \end{cases} \]  

\[ (a_1) : \] This solution may be relevant to the early radiation dominant universe and to its late accelerated expansion. The solution mimics interference between expansion with scalar curvature \( R \) and an eigenvalue problem.

Let us consider the scale factor

\[ a(t) = (\alpha e^{Lt} + \beta e^{-Lt})^\gamma, \]  

and an eigenvalue problem

\[ \square(R - 4\Lambda) = q(R - 4\Lambda) = \zeta \Lambda(R - 4\Lambda), \]  

for a dimensionless constant \( \zeta \) that will be determined later. The equality \( (3.18) \) can be expanded into

\[ \left( \beta + \alpha e^{2Lt} \right)^2 \left( A_0 + A_1 e^{2Lt} + A_2 e^{4Lt} \right) + 2 \left( \alpha e^{Lt} + \beta e^{-Lt} \right)^{2\gamma} \left( B_0 + B_1 e^{2Lt} + B_2 e^{4Lt} + B_3 e^{6Lt} + B_4 e^{8Lt} \right) = 0, \]  

where

\[ A_0 = 3k\beta^2 \left( q - 2\gamma^2 \lambda^2 \right), \]
\[ A_1 = 6k\alpha \beta \left( 2(\gamma - 2)\gamma \lambda^2 + q \right), \]
\[ A_2 = 3k\alpha^2 \left( q - 2\gamma^2 \lambda^2 \right), \]  

and

\[ B_0 = \beta^4 \left( 3\gamma^2 \lambda^2 - \Lambda \right), \]
\[ B_1 = 2\alpha \beta^3 \left( 6\gamma \left( 6\gamma^2 - 7\gamma + 2 \right) \lambda^4 + q \left( 3\gamma \lambda^2 - 2\Lambda \right) \right), \]
\[ B_2 = -6\alpha^2 \beta^2 \left( \gamma \left( 6\gamma^2 - 11\gamma + 4 \right) \lambda^4 + q \left( \gamma^2 \lambda^2 - 2\gamma \lambda^2 + \Lambda \right) \right), \]
\[ B_3 = 2\alpha^3 \beta \left( 6\gamma \left( 6\gamma^2 - 7\gamma + 2 \right) \lambda^4 + q \left( 3\gamma \lambda^2 - 2\Lambda \right) \right), \]
\[ B_4 = \alpha^4 q \left( 3\gamma^2 \lambda^2 - \Lambda \right). \]

In the case \( \alpha \beta = 0 \), i.e. \( \alpha = 0 \) or \( \beta = 0 \), the eigenvalue problem \( \square(R - 4\Lambda) = q(R - 4\Lambda) \) has nontrivial solution in the following two cases:

### 3.2 Eigenvalue Problem for New Cosmological Solutions

Let us consider the scale factor

\[ a(t) = (\alpha e^{Lt} + \beta e^{-Lt})^\gamma, \]  

and an eigenvalue problem

\[ \square(R - 4\Lambda) = q(R - 4\Lambda) = \zeta \Lambda(R - 4\Lambda), \]  

for a dimensionless constant \( \zeta \) that will be determined later. The equality \( (3.18) \) can be expanded into

\[ \left( \beta + \alpha e^{2Lt} \right)^2 \left( A_0 + A_1 e^{2Lt} + A_2 e^{4Lt} \right) + 2 \left( \alpha e^{Lt} + \beta e^{-Lt} \right)^{2\gamma} \left( B_0 + B_1 e^{2Lt} + B_2 e^{4Lt} + B_3 e^{6Lt} + B_4 e^{8Lt} \right) = 0, \]  

where

\[ A_0 = 3k\beta^2 \left( q - 2\gamma^2 \lambda^2 \right), \]
\[ A_1 = 6k\alpha \beta \left( 2(\gamma - 2)\gamma \lambda^2 + q \right), \]
\[ A_2 = 3k\alpha^2 \left( q - 2\gamma^2 \lambda^2 \right), \]  

and

\[ B_0 = \beta^4 \left( 3\gamma^2 \lambda^2 - \Lambda \right), \]
\[ B_1 = 2\alpha \beta^3 \left( 6\gamma \left( 6\gamma^2 - 7\gamma + 2 \right) \lambda^4 + q \left( 3\gamma \lambda^2 - 2\Lambda \right) \right), \]
\[ B_2 = -6\alpha^2 \beta^2 \left( \gamma \left( 6\gamma^2 - 11\gamma + 4 \right) \lambda^4 + q \left( \gamma^2 \lambda^2 - 2\gamma \lambda^2 + \Lambda \right) \right), \]
\[ B_3 = 2\alpha^3 \beta \left( 6\gamma \left( 6\gamma^2 - 7\gamma + 2 \right) \lambda^4 + q \left( 3\gamma \lambda^2 - 2\Lambda \right) \right), \]
\[ B_4 = \alpha^4 q \left( 3\gamma^2 \lambda^2 - \Lambda \right). \]
1. $k = 0$, $\Lambda = 3\gamma^2 \lambda^2$
2. $k \neq 0$, $q = 2\gamma^2 \lambda^2$, $\Lambda = 3\gamma^2 \lambda^2$.

When $\alpha \beta \neq 0$ then functions $e^{2\lambda t}$ and $(\alpha e^{\lambda t} + \beta e^{-\lambda t})^{2\gamma}$ are linearly independent. In this case we can split equation (3.19) into

$$A_0 = A_1 = A_2 = 0, \quad B_0 = B_1 = B_2 = B_3 = B_4 = 0.$$  (3.22)

The previous equations (3.22) are satisfied in the following two cases:

1. $\gamma = 1$, $q = 2\lambda^2$, $\Lambda = 3\lambda^2$, $k \in \{0, -1, 1\}$, (3.23)
2. $\gamma = \frac{1}{2}$, $\Lambda = \frac{3}{4} \lambda^2$, $k = 0$. (3.24)

Hence, the only two possibilities for parameter $\gamma$ are: $\gamma = 1$ and $\gamma = \frac{1}{2}$.

Now, let us consider the scale factor

$$a(t) = (\alpha \cos \lambda t + \beta \sin \lambda t)^\gamma,$$  (3.25)

and the corresponding eigenvalue problem

$$\Box (R - 4\Lambda) = q(R - 4\Lambda).$$  (3.26)

Similarly as in the previous case, if we replace $\lambda$ by $i\lambda$ in the scale factor $a(t) = (\alpha e^{\lambda t} + \beta e^{-\lambda t})^{2\gamma}$ we obtain that the eigenvalue problem (3.26) has solution in the following two cases:

1. $\gamma = 1$, $q = -2\lambda^2$, $\Lambda = -3\lambda^2$, $k \in \{0, -1, 1\}$, (3.27)
2. $\gamma = \frac{1}{2}$, $\Lambda = -\frac{3}{4} \lambda^2$, $k = 0$. (3.28)

As result of the solution of eigenvalue problem (3.18) we obtained not only concrete eigenvalue $q$ but also possible values of $\gamma$ and $\lambda$ for the cosmic scale factor of the form (3.17) and (3.25). In fact, we have found that nonlocal gravity model (2.1) may have the following new cosmological solutions:

$$a_3(t) = \alpha e^{\sqrt{-\frac{1}{3} \Lambda} t} + \beta e^{-\sqrt{-\frac{1}{3} \Lambda} t}, \quad \Lambda \geq 0,$$  (3.29)

$$a_4(t) = \left(\alpha e^{2\sqrt{-\frac{1}{3} \Lambda} t} + \beta e^{-2\sqrt{-\frac{1}{3} \Lambda} t}\right)^\frac{1}{2}, \quad \Lambda \geq 0,$$  (3.30)

$$a_5(t) = \alpha \cos \sqrt{-\frac{1}{3} \Lambda} t + \beta \sin \sqrt{-\frac{1}{3} \Lambda} t, \quad \Lambda \leq 0,$$  (3.31)

$$a_6(t) = \left(\alpha \cos 2\sqrt{-\frac{1}{3} \Lambda} t + \beta \sin 2\sqrt{-\frac{1}{3} \Lambda} t\right)^\frac{1}{2}, \quad \Lambda \leq 0.$$  (3.32)

By additional requirement that scale factors (3.29) – (3.32) satisfy equations of motion (3.3) and (3.4) gives possibility to determine values of $\alpha$ and $\beta$, fix curvature constant $k$ and obtain constraints on $F(\Box)$ and $F'(\Box)$. In the following four subsections we give more details.
3.3 Cosmological Solution of the Form \( a_3(t) = \alpha e^{\sqrt{\Lambda} t} + \beta e^{-\sqrt{\Lambda} t} \)

In this case we have

\[
\dot{a}(t) = \sqrt{\Lambda} \left( \alpha e^{\sqrt{\Lambda} t} - \beta e^{-\sqrt{\Lambda} t} \right), \quad \ddot{a}(t) = \frac{\Lambda}{3} a(t), \quad (3.33)
\]

\[
R(t) = 4\Lambda + (6k - 8\Lambda \alpha \beta) a(t)^{-2}, \quad (3.34)
\]

\[
H(t) = \sqrt{\frac{\Lambda}{3}} \left( 1 - 2\beta e^{-\sqrt{\Lambda} t} a(t)^{-1} \right), \quad (3.35)
\]

\[
R_{00} = -\Lambda, \quad G_{00} = \Lambda + (3k - 4\Lambda \alpha \beta) a(t)^{-2}. \quad (3.36)
\]

The corresponding eigenvalue problem has the following solution:

\[
\square (R - 4\Lambda) = \frac{2}{3} \Lambda (R - 4\Lambda), \quad F(\square)(R - 4\Lambda) = F \left( \frac{2}{3} \Lambda \right) (R - 4\Lambda). \quad (3.37)
\]

Using the solution of eigenvalue problem (3.37), the trace and 00-component of EOM are:

\[
\begin{align*}
T_0 &= \beta^4 \left( 12 \Lambda F \left( \frac{2}{3} \Lambda \right) - 1 \right), \\
T_1 &= 4\alpha \beta^3 \left( 12 \Lambda F \left( \frac{2}{3} \Lambda \right) - 1 \right), \\
T_2 &= -6\alpha \beta \left( \alpha \beta \left( 1 - 12 \Lambda F \left( \frac{2}{3} \Lambda \right) \right) - \frac{16}{3} \Lambda F' \left( \frac{2}{3} \Lambda \right) (k - 4\alpha \beta \Lambda / 3) \right), \\
T_3 &= 4\alpha^3 \beta \left( 12 \Lambda F \left( \frac{2}{3} \Lambda \right) - 1 \right), \\
T_4 &= \alpha^4 \left( 12 \Lambda F \left( \frac{2}{3} \Lambda \right) - 1 \right),
\end{align*}
\]

and

\[
\begin{align*}
Z_0 &= \beta^4 \left( 1 - 12 \Lambda F \left( \frac{2}{3} \Lambda \right) \right), \\
Z_1 &= 2\beta^2 \left( 2\alpha \beta - 6 \Lambda F' \left( \frac{2}{3} \Lambda \right) \right) \left( k - 4\alpha \beta \Lambda / 3 \right) + 3F \left( \frac{2}{3} \Lambda \right) (k - 4\alpha \beta \Lambda), \\
Z_2 &= 6\alpha \beta \left( \alpha \beta + \frac{4}{3} \Lambda F' \left( \frac{2}{3} \Lambda \right) \right) \left( k - 4\alpha \beta \Lambda / 3 \right) + 2F \left( \frac{2}{3} \Lambda \right) (k - 2\alpha \beta \Lambda), \\
Z_3 &= 2\alpha^2 \left( 2\alpha \beta - 6 \Lambda F' \left( \frac{2}{3} \Lambda \right) \right) \left( k - 4\alpha \beta \Lambda / 3 \right) + 3F \left( \frac{2}{3} \Lambda \right) (k - 4\alpha \beta \Lambda), \\
Z_4 &= \alpha^4 \left( 1 - 12 \Lambda F \left( \frac{2}{3} \Lambda \right) \right).
\end{align*}
\]
These two equations are polynomials in $e^{2\sqrt{\Lambda}t}$. Both equations are clearly satisfied if $\alpha\beta = \frac{3k}{4\Lambda}$. On the other hand, if $\alpha\beta \neq \frac{3k}{4\Lambda}$ it remains to solve the system of equations

$$
T_0 = T_1 = T_2 = T_3 = T_4 = 0, \quad Z_0 = Z_1 = Z_2 = Z_3 = Z_4 = 0. \quad (3.42)
$$

Equations of motion are satisfied in the following three nontrivial cases:

(i) : $\alpha\beta = \frac{3k}{4\Lambda}$

$$
(i) : \quad \alpha\beta = \frac{3k}{4\Lambda}, \quad (3.43)
$$

(ii) : $\alpha\beta = 0, \quad F(\frac{2}{3} \Lambda) = \frac{1}{12\Lambda}, \quad F'(\frac{2}{3} \Lambda) = \frac{1}{24\Lambda^2}, \quad k \neq 0,$

$$
(ii) : \quad \alpha\beta = 0, \quad F(\frac{2}{3} \Lambda) = \frac{1}{12\Lambda}, \quad F'(\frac{2}{3} \Lambda) = 0. \quad (3.44)
$$

(iii) : $\alpha\beta = -\frac{k}{4\Lambda}, \quad F(\frac{2}{3} \Lambda) = \frac{1}{12\Lambda}, \quad F'(\frac{2}{3} \Lambda) = 0.$

$$
(iii) : \quad \alpha\beta = -\frac{k}{4\Lambda}, \quad F(\frac{2}{3} \Lambda) = \frac{1}{12\Lambda}, \quad F'(\frac{2}{3} \Lambda) = 0. \quad (3.45)
$$

(i): In the first case, we have $R(t) = 4\Lambda$. For $k = 0$ we have $\alpha\beta = 0$ and consequently, $a(t) \sim e^{k \sqrt{\Lambda}t}$. Also since $\Lambda > 0$, $a(t) = \sqrt{\frac{\Lambda}{k}} \cosh \sqrt{\frac{\Lambda}{3}t}$ requires $k = +1$, while $a(t) = \sqrt{\frac{\Lambda}{k}} \sinh \sqrt{\frac{\Lambda}{3}t}$ if $k = -1$.

(ii): In the second case $\alpha = 0$ or $\beta = 0$. For $\alpha = 0$ we have $a(t) = \beta e^{-\sqrt{\Lambda}t}$ and $R(t) = 6ka(t)^{-2} + 4\Lambda$. Analogously, for $\beta = 0$ we have $a(t) = \alpha e^{\sqrt{\Lambda}t}$ and $R(t) = 6ka(t)^{-2} + 4\Lambda$.

(iii): In the third case, we have $R(t) = 4\Lambda + 8ka(t)^{-2}$. If $k = -1$ there is $\varphi$ such that $\alpha + \beta = \frac{1}{\sqrt{\Lambda}} \cosh \varphi, \quad \alpha - \beta = \frac{1}{\sqrt{\Lambda}} \sinh \varphi. \quad (3.46)$

Now, we can transform scale factor $a(t) = \alpha e^{\sqrt{\Lambda}t} + \beta e^{-\sqrt{\Lambda}t}$ to

$$
a(t) = \frac{1}{\sqrt{\Lambda}} \cosh(\varphi + \sqrt{\frac{\Lambda}{3}}t), \quad k = -1. \quad (3.46)
$$

If $k = +1$ there is such $\varphi$ that

$$
\alpha + \beta = \frac{1}{\sqrt{\Lambda}} \sinh \varphi, \quad \alpha - \beta = \frac{1}{\sqrt{\Lambda}} \cosh \varphi. \quad (3.46)
$$

Consequently, we can transform scale factor $a(t) = \alpha e^{\sqrt{\Lambda}t} + \beta e^{-\sqrt{\Lambda}t}$ to

$$
a(t) = \frac{1}{\sqrt{\Lambda}} \sinh(\varphi + \sqrt{\frac{\Lambda}{3}}t). \quad (3.47)
$$

Effective energy density and pressure are given by:

$$
\bar{\rho} = \frac{3}{8\pi G} (k - \frac{4}{3} \Lambda \alpha\beta)a(t)^{-2}, \quad \bar{p} = -\frac{1}{8\pi G} (k - \frac{4}{3} \Lambda \alpha\beta)a(t)^{-2}. \quad (3.48)
$$

For $k \neq \frac{4}{3} \Lambda \alpha\beta$ the corresponding $\bar{w}$ parameter is $\bar{w} = -\frac{4}{3}$.

### 3.4 Cosmological Solutions of the Form $a_4(t) = \left(\alpha e^{2\sqrt{\Lambda}t} + \beta e^{-2\sqrt{\Lambda}t}\right)^{\frac{1}{2}}$

According to solution (3.24) of the related eigenvalue problem, in this case $k = 0$. The corresponding Ricci scalar is

$$
R = 4\Lambda. \quad (3.49)
$$
The EOM yield the condition
\[ \alpha \beta = 0. \]  
(3.50)

Hence, there are only solutions \( a(t) \sim e^{\pm \sqrt{\Lambda} t} \), what is just we have in the Einstein theory of gravity. Since the corresponding eigenvalue is zero, i.e. \( \Box (R - 4 \Lambda) = 0 \), solutions of the form \( a_4(t) = (\alpha e^{2\sqrt{\Lambda} t} + \beta e^{-2\sqrt{\Lambda} t})^{1/2} \) are trivial at the classical level from the point of view of nonlocal gravity model under consideration.

### 3.5 Cosmological Solutions of the Form \( a_5(t) = \alpha \cos \sqrt{-\frac{\Lambda}{3}} t + \beta \sin \sqrt{-\frac{\Lambda}{3}} t \)

In this case we have
\[ \dot{a}(t) = \sqrt{\frac{\Lambda}{3}} (\beta \cos \sqrt{-\frac{\Lambda}{3}} t - \alpha \sin \sqrt{-\frac{\Lambda}{3}} t), \quad \ddot{a}(t) = \frac{\Lambda}{3} a(t), \]  
(3.51)
\[ R(t) = 4\Lambda + 6(k - (\alpha^2 + \beta^2) \frac{\Lambda}{3}) a(t)^{-2}, \]  
(3.52)
\[ H(t) = \sqrt{-\frac{\Lambda}{3}} (\beta \cos \sqrt{-\frac{\Lambda}{3}} t - \alpha \sin \sqrt{-\frac{\Lambda}{3}} t) a(t)^{-1}, \]  
(3.53)
\[ R_{00} = -\Lambda, \quad G_{00} = 3(k - (\alpha^2 + \beta^2) \frac{\Lambda}{3}) a(t)^{-2} - 2. \]  
(3.54)

The corresponding eigenvalue problem has the same solution as in the previous case (3.37), i.e.
\[ \Box (R - 4\Lambda) = \frac{2}{3} \Lambda (R - 4\Lambda), \quad F(\Box)(R - 4\Lambda) = F(\frac{2}{3} \Lambda)(R - 4\Lambda). \]  
(3.55)

Trace and 00-component of equations of motion read
\[ \left( k - \frac{\Lambda}{3} \alpha^2 + \beta^2 \right) \left( U_0 + U_1 e^{2i\sqrt{-\frac{\Lambda}{3}} t} + U_2 e^{4i\sqrt{-\frac{\Lambda}{3}} t} + U_3 e^{6i\sqrt{-\frac{\Lambda}{3}} t} + U_4 e^{8i\sqrt{-\frac{\Lambda}{3}} t} \right) = 0, \]  
(3.56)
\[ \left( k - \frac{\Lambda}{3} \alpha^2 + \beta^2 \right) \left( V_0 + V_1 e^{2i\sqrt{-\frac{\Lambda}{3}} t} + V_2 e^{4i\sqrt{-\frac{\Lambda}{3}} t} + V_3 e^{6i\sqrt{-\frac{\Lambda}{3}} t} + V_4 e^{8i\sqrt{-\frac{\Lambda}{3}} t} \right) = 0, \]  
(3.57)
where
\[ U_0 = (\alpha + i \beta)^4 \left( 1 - 12 \Lambda F \left( \frac{2}{3} \Lambda \right) \right), \]
\[ U_1 = 4(\alpha + i \beta)^3 (\alpha - i \beta) \left( 1 - 12 \Lambda F \left( \frac{2}{3} \Lambda \right) \right), \]
\[ U_2 = 6 (\alpha^2 + \beta^2) \left( (\alpha^2 + \beta^2) \left( 1 + \frac{64}{9} \Lambda^2 F^2 \left( \frac{2}{3} \Lambda \right) - 12 \Lambda F \left( \frac{2}{3} \Lambda \right) \right) - 64 \Lambda^2 F^2 \left( \frac{2}{3} \Lambda \right) \right), \]
\[ U_3 = 4(\alpha + i \beta)(\alpha - i \beta)^3 \left( 1 - 12 \Lambda F \left( \frac{2}{3} \Lambda \right) \right), \]
\[ U_4 = (\alpha - i \beta)^4 \left( 1 - 12 \Lambda F \left( \frac{2}{3} \Lambda \right) \right), \]  
(3.58)
and
\[V_0 = (\alpha + i\beta)^4 \left(1 - 12\Lambda F \left(\frac{2}{3}\Lambda\right)\right),\]
\[V_1 = 4(\alpha + i\beta)^2 \left((\alpha^2 + \beta^2) \left(1 + 4\Lambda^2 F' \left(\frac{2}{3}\Lambda\right) - 6\Lambda F \left(\frac{2}{3}\Lambda\right)\right) + 6k \left(F \left(\frac{2}{3}\Lambda\right) - 2\Lambda F' \left(\frac{2}{3}\Lambda\right)\right)\right),\]
\[V_2 = 6(\alpha^2 + \beta^2) \left((\alpha^2 + \beta^2) \left(1 - \frac{16}{9}\Lambda^2 F' \left(\frac{2}{3}\Lambda\right) - 4\Lambda F \left(\frac{2}{3}\Lambda\right)\right) + 8k \left(F \left(\frac{2}{3}\Lambda\right) + \frac{2}{3}\Lambda F' \left(\frac{2}{3}\Lambda\right)\right)\right),\]
\[V_3 = 4(\alpha - i\beta)^2 \left((\alpha^2 + \beta^2) \left(1 + 4\Lambda^2 F' \left(\frac{2}{3}\Lambda\right) - 6\Lambda F \left(\frac{2}{3}\Lambda\right)\right) + 6k \left(F \left(\frac{2}{3}\Lambda\right) - 2\Lambda F' \left(\frac{2}{3}\Lambda\right)\right)\right),\]
\[V_4 = (\alpha - i\beta)^4 \left(1 - 12\Lambda F \left(\frac{2}{3}\Lambda\right)\right).\]

We consider these equations as polynomials in $e^{2i\sqrt{-\Lambda}t}$. It is clear that equations are satisfied for $\alpha^2 + \beta^2 = \frac{3k}{\Lambda}$. In the other case, $\alpha^2 + \beta^2 \neq \frac{3k}{\Lambda}$ it remains to solve the following system of equations
\[U_0 = U_1 = U_2 = U_3 = U_4 = 0, \quad V_0 = V_1 = V_2 = V_3 = V_4 = 0.\]

Equations of motion are satisfied in the following two nontrivial cases:

(i): $\alpha^2 + \beta^2 = \frac{3k}{\Lambda},$ \hspace{1cm} (3.61)
(ii): $F \left(\frac{2}{3}\Lambda\right) = \frac{1}{12\Lambda}, \quad F' \left(\frac{2}{3}\Lambda\right) = 0, \quad \alpha^2 + \beta^2 = -\frac{k}{\Lambda}.$ \hspace{1cm} (3.62)

(i): In the first case, we have $R(t) = 4\Lambda$.
(ii): In the second case, we have $R(t) = 4\Lambda + 8k\alpha(t)^{-2}$. Taking $k = +1$, there exists $\varphi$ such that
\[\alpha = \frac{1}{\sqrt{-\Lambda}} \sin \varphi, \quad \beta = \frac{1}{\sqrt{-\Lambda}} \cos \varphi.\]

Now, we can transform scale factor $a(t) = \alpha \cos \sqrt{-\frac{\Lambda}{3}} t + \beta \sin \sqrt{-\frac{\Lambda}{3}} t$ to
\[a(t) = \frac{1}{\sqrt{-\Lambda}} \sin \left(\sqrt{-\frac{\Lambda}{3}} t - \varphi\right).\] \hspace{1cm} (3.63)

Effective energy density and pressure are:
\[\bar{\rho} = \frac{3k - \Lambda(\alpha^2 + \beta^2)}{8\pi G a(t)^2}, \quad \bar{p} = \frac{\Lambda(\alpha^2 + \beta^2) - 3k}{24\pi G a(t)^2}.\] \hspace{1cm} (3.64)

For $k \neq \frac{3}{4}(\alpha^2 + \beta^2)$ we have $\bar{w} = -\frac{1}{3}$. 

12
3.6 Cosmological Solutions of the Form $a_6(t) = \left( \alpha \cos 2\sqrt{-\frac{\Lambda}{3}} t + \beta \sin 2\sqrt{-\frac{\Lambda}{3}} t \right)^{\frac{1}{2}}$

In this case

\[ R = 4\Lambda, \quad k = 0. \tag{3.65} \]

From equations of motion follows

\[ \alpha^2 + \beta^2 = 0. \tag{3.66} \]

Hence, there are no nontrivial solutions of the form

\[ a_6(t) = \left( \alpha \cos 2\sqrt{-\frac{\Lambda}{3}} t + \beta \sin 2\sqrt{-\frac{\Lambda}{3}} t \right)^{\frac{1}{2}}. \]

4 Discussion and Conclusions

To have more complete presentation of the contents of this paper, some main considerations should be discussed. These considerations include gained new cosmological solutions, used eigenvalue method and nonlocal operator.

On new cosmological solutions. Section 3 is related to the finding of new cosmological solutions of nonlocal gravity model \((2.1)\). In a class of possible scale factors of the form

\[ a(t) = (\alpha e^{\lambda t} + \beta e^{-\lambda t})^\gamma, \quad \beta \neq 1 \]

we have found four new solutions when \(\gamma = 1\) and no nontrivial solutions if \(\gamma \neq 1\). The new solutions are:

\[ a(t) = A e^{\pm \sqrt{\frac{\Lambda}{3}} t}, \quad R(t) = \frac{6k}{A^2} e^{\mp 2\sqrt{\frac{\Lambda}{3}} t} + 4\Lambda, \quad k = +1, -1, \quad \Lambda > 0. \tag{4.1} \]

\[ a(t) = \frac{1}{\sqrt{\Lambda}} \cosh \left( \sqrt{\frac{\Lambda}{3}} t \right), \quad R(t) = 8k\Lambda \frac{1}{\cosh^2 \left( \sqrt{\frac{\Lambda}{3}} t \right)} + 4\Lambda, \quad k = -1, \quad \Lambda > 0. \tag{4.2} \]

\[ a(t) = \frac{1}{\sqrt{-\Lambda}} \sinh \left( \sqrt{\frac{\Lambda}{3}} t \right), \quad R(t) = 8k\Lambda \frac{1}{\sinh^2 \left( \sqrt{\frac{\Lambda}{3}} t \right)} + 4\Lambda, \quad k = +1, \quad \Lambda > 0. \tag{4.3} \]

\[ a(t) = \frac{1}{\sqrt{-\Lambda}} \sin \left( \sqrt{\frac{-\Lambda}{3}} t \right), \quad R(t) = -8k\Lambda \frac{1}{\sin^2 \left( \sqrt{\frac{-\Lambda}{3}} t \right)} + 4\Lambda, \quad k = +1, \quad \Lambda < 0. \tag{4.4} \]

Recall that in the de Sitter (anti-de Sitter) \((2.4)\) case analogous solutions are:

\[ a(t) = A e^{\pm \sqrt{\frac{\Lambda}{3}} t}, \quad R = 4\Lambda, \quad k = 0, \quad \Lambda > 0. \tag{4.5} \]

\[ a(t) = \sqrt{\frac{3}{\Lambda}} \cosh \left( \sqrt{\frac{\Lambda}{3}} t \right), \quad R = 4\Lambda, \quad k = +1, \quad \Lambda > 0. \tag{4.6} \]

\[ a(t) = \sqrt{\frac{3}{\Lambda}} \sinh \left( \sqrt{\frac{\Lambda}{3}} t \right), \quad R = 4\Lambda, \quad k = -1, \quad \Lambda > 0. \tag{4.7} \]

\[ a(t) = \sqrt{-\frac{3}{\Lambda}} \sin \left( \sqrt{\frac{-\Lambda}{3}} t \right), \quad R = 4\Lambda, \quad k = -1, \quad \Lambda < 0. \tag{4.8} \]

Comparing \((4.1) - (4.4)\) with \((4.5) - (4.8)\) we can note that for the same cosmological constant \(\Lambda\) there are analogous scale factors with the same time dependence, but with different curvature constant \(k\). This fact can be interpreted as change of topology in de Sitter (anti-de Sitter) space by inclusion of nonlocal term of the form \((R - 4\Lambda)\mathcal{F}(\Box)(R - 4\Lambda)\), see \((2.1)\). For
example, exponential expansion \(^{14a}\) in a flat de Sitter universe remains exponential \(^{14a}\) by nonlocal transition into closed or open de Sitter space. We can also conclude that this kind of nonlocality changes constant space-time curvature \((\mathcal{R} = 4\Lambda)\) to the time dependent one \((\mathcal{R} = \mathcal{R}(t))\). It is worth noting that in nonlocal square root gravity model \(^{2.2}\) there is cosmological solution with the scale factor \(a(t) = A e^{\sqrt{\frac{2}{3}\Lambda} t} \), \(\Lambda > 0\), \(k = +1, -1\), with scalar curvature \(\mathcal{R}(t) = \frac{6k}{A^2} e^{\frac{2}{3}\sqrt{\frac{2}{3}\Lambda} t} + 2\Lambda\), see Sec. 3.3 in \(^{48}\). This case is similar to \(^{1.1}\) presented in this paper. We expect that analogous cases exist in some other examples of transition from local to nonlocal de Sitter model.

**On eigenvalue method.** In our approach, to solve equations of motion in the case of a homogeneous and isotropic universe, essential role plays possibility to solve the corresponding eigenvalue problem \((\Box (\mathcal{R}(t) - 4\Lambda) = q (\mathcal{R}(t) - 4\Lambda))\), where \(q = \zeta \Lambda\). \(\Lambda\) appears here on the basis of dimensionality. Analogous solutions of \(^{4.1} - ^{4.4}\) and \(^{4.5} - ^{4.8}\) have the same Hubble parameter \(H(t) = \frac{\dot{a}}{a}\) and consequently the same d’Alembert-Beltrami operator \(\Box = -\frac{\partial^2}{\partial t^2} - 3H(t) \frac{\partial}{\partial a}\).

One can easily see that solution of \((\Box (\mathcal{R} - 4\Lambda) = q (\mathcal{R} - 4\Lambda))\) implies solution of the following eigenvalue problem:

\[
\Box^{-1} (\mathcal{R} - 4\Lambda) = q^{-1} (\mathcal{R} - 4\Lambda), \quad q \neq 0.
\]  

(4.9)

In other words, operators \(\Box\) and \(\Box^{-1}\) have the same eigenfunctions \(\mathcal{R}(t) - 4\Lambda\), but with different eigenvalues \(q\) and \(1/q\), when \(q \neq 0\).

**On nonlocal operator.** Solvability of eigenvalue problem \(^{4.9}\) gives rise to introduce an extended version of the nonlocal operator \(\mathcal{F}(\Box) = \sum_{n=1}^{\infty} f_n \Box^n\) to the following one:

\[
\mathcal{F}(\Box) = \sum_{n=-\infty}^{\infty} f_n \Box^n = \sum_{n=1}^{\infty} f_n \Box^n + f_0 + \sum_{n=1}^{\infty} f_{-n} \Box^{-n},
\]

(4.10)

where \(f_0 = 0\) in \(^{2.1}\) nonlocal gravity model. Note that nonlocal operator \(^{4.10}\) is symmetric under interchange \(n \leftrightarrow -n\). This extended nonlocal operator satisfies eigenvalue problem \(\mathcal{F}(\Box) (\mathcal{R} - 4\Lambda) = \mathcal{F}(q)(\mathcal{R} - 4\Lambda)\), where

\[
\mathcal{F}(q) = \sum_{n \neq 0} f_n q^n = \sum_{n=1}^{\infty} f_n q^n + \sum_{n=1}^{\infty} f_{-n} q^{-n}.
\]  

(4.11)

In Section 3, we could replace \(\mathcal{F}(\Box)\) by this one in \(^{4.10}\) with \(f_0 = 0\), and the same new scale factors would be obtained with the same constraints on this extended \(\mathcal{F}(\Box)\). Note that now eigenvalues are: \(q = \frac{2}{3}\Lambda\), \(\Lambda \neq 0\) and \(q^{-1} = \frac{3}{2}\Lambda\), \(\Lambda \neq 0\) for all four new solutions.

Note that finding of each new cosmological solution induces two restrictions on nonlocal operator \(\mathcal{F}(\Box)\). At this stage an explicit form of \(\mathcal{F}(\Box)\) is not necessary.

**On further investigations.** Absence of the additional degrees of freedom, in particular ghosts, should be an important property of nonlocal gravity. A ghost-free condition is investigated in paper \(^{43}\) for models of form \(^{1.1}\), which includes our model \(^{2.1}\), see also \(^{21, 50}\) and references therein. To avoid a ghost, nonlocal operator \(\mathcal{F}\) must satisfy some conditions that depend on the background cosmological solution. This needs detailed investigation of the second variation \(^{19}\) of action \(^{1.1}\) and is a subject for future consideration.

As it is shown in Section 2, nonlocal gravity model \(^{2.1}\) can be derived from nonlocal de Sitter gravity \(^{2.2}\). These two models together contain cosmological solutions that mimic interference of dark energy with radiation and dark matter in the flat universe. Both models also have a nonsingular bounce solution. Hence, at the cosmological scale, these nonlocal
models imitate some effects that are a part of cosmic history described by standard model of cosmology (ΛCDM model). This situation gives rise to continue with developments of this nonlocal gravity approach and explore influence on astrophysical effects at galactic scale and the Solar system. It should be also investigated possible inflation, cosmic microwave background (CMB) and cosmological perturbations [51].

Conclusions. At the end, it is worth noting the main results presented in this paper.

- Four new exact cosmological solutions are obtained.
- Effective energy density and effective pressure are computed for all new solutions.
- Change of space topology by nonlocal gravity is noted.
- A connection between nonlocal gravity models (2.1) and (2.2) is shown.
- Method of finding eigenfunctions $R(t) - 4\Lambda$ is further elaborated.
- Nonlocal operator $\mathcal{F}(\Box)$ can be naturally extended by addition of $\Box^{-1}$ in a symmetric way.
