Abstract

We formulate a general set of consistency requirements, which are expected to be satisfied by the scattering matrices in the presence of reflecting boundaries. In particular we derive an equivalent to the bootstrap equation involving the W-matrix, which encodes the reflection of a particle off a wall. This set of equations is sufficient to derive explicit formulas for $W$, which we illustrate in the case of some particular affine Toda field theories.

1 Introduction

The common procedure to treat the scattering of particles is to work in infinitely extended space-time. Yet restricting the space volume to finite size may reveal interesting information, which is not observable in the infinite volume limit. In completely integrable models the modifications arising from the presence of boundaries can be computed exactly. We therefore direct our interest to integrable models on a finite line delimited by perfectly reflecting mirrors. The central object is the $S$-matrix, which is factorized into 2-body $S$-matrices in this case. They have to satisfy Yang-Baxter\cite{1,2} equations, which provide nontrivial constraints for non-diagonal matrices. In the presence of reflecting boundaries one obtains similar factorization equations including the \textit{wall matrix} $W$, which describes the scattering of a particle off the wall\cite{3,4,5}.

The main object of the present paper is to study scattering described by diagonal $S$-matrices. In this case the nontrivial constraints result from the bootstrap hypothesis, which we formulate for the situation with finite space volume. Whilst in the situation without boundaries the ensuing consistency equations allow us to determine explicitly the $S$-matrix\cite{6,7}, in the present situation they will enable us to compute the $W$-matrix.

The layout of this article is as follows. Firstly we extend the Zamolodchikov algebra including the wall matrix $W$ to take boundaries into account. In section 3 we employ it to derive the factorization equations in the presence of reflecting boundaries and in section 4 we formulate our central equations\cite{4,13}, the \textit{wall bootstrap} equations. In section 5 we apply this framework to the 1-particle Bullough-Dodd model ($A_2^{(2)}$-affine Toda theory) and to several 2-particle affine Toda systems ($A_2^{(1)}$ and $A_4^{(2)}$). Finally we state our conclusions.
2 Zamolodchikov algebra

Factorized $S$-matrices, describing one-dimensional scattering, have to satisfy certain consistency conditions, which in general provide powerful tools for their explicit construction. These axioms can be extracted most easily as associativity conditions of the well known Zamolodchikov algebra [2]

\begin{align}
Z_a(\theta_a)Z_b(\theta_b) &= S^{ab}_{\bar{a}b}(\theta_{ab}) Z_{\bar{b}}(\theta_{b}) Z_{\bar{a}}(\theta_{a}) \quad (2.1) \\
Z^\dagger_a(\theta_a)Z^\dagger_b(\theta_b) &= S^{\bar{a}b}_{ab}(\theta_{ab}) Z^\dagger_{\bar{b}}(\theta_{b}) Z^\dagger_{\bar{a}}(\theta_{a}) \quad (2.2) \\
Z_a(\theta_a)Z^\dagger_b(\theta_b) &= S^{ab}_{\bar{a}b}(\theta_{ba}) Z^\dagger_{\bar{b}}(\theta_{b}) Z_{\bar{a}}(\theta_{a}) + 2\pi \delta_{ab} \delta(\theta_{ab}) \quad (2.3)
\end{align}

where each of the operators $Z_a$ is associated with a particle “$a$” and $S$ denotes the unitary and crossing invariant two particle scattering matrix which satisfy the Yang-Baxter-(3.9) and bootstrap equation (4.13). Their dependence on the momenta is parameterized usually by the rapidities $\theta_a$, i.e. $p_a = m(\cosh \theta_a, \sinh \theta_a)$, having the advantage that the branch cuts on the real axis in the complex plane of the Mandelstam variable unfold. Relativistic invariance demands that the scattering matrix depends only on the rapidity difference, which we denote $\theta_{ab} := \theta_a - \theta_b$.

In the present case this operator algebra has to be extended in order to include the presence of a wall. When a particle scatters off the wall, it reverses its momentum and possibly changes its quantum numbers. If $Z_a(\theta)$ represents particle $a$ and $Z_w(0)$ represents the wall in Zamolodchikov’s algebra, this process is encoded in the following relation

\begin{equation}
Z_a(\theta)Z_w(0) = \sum_{\bar{a}} W^\bar{a}_a(\theta) Z_{\bar{a}}(\tilde{\theta}) Z_w(0), \quad (2.4)
\end{equation}

where $\tilde{\theta} = -\theta$ and the matrix $W^\bar{a}_a(\theta)$ describes the scattering by the wall. Notice that we do not interchange the order of $Z_a$ and $Z_w$ as in (2.1)-(2.3), such that the $W$-matrix is not the result of a braiding like the scattering matrix. From its definition, $W^\bar{a}_a(\theta)$ has to satisfy the usual unitarity condition

\begin{equation}
\sum_{\bar{a}} W^\bar{a}_a(\theta)W^\bar{a}_a(-\theta) = \delta^a_{a'}, \quad (2.5)
\end{equation}
The algebra, involving $Z_a \ '$s and $Z^\dagger_a \ '$ only, is now very similar to the usual case (2.1) - (2.3), except that in the process $a + b \rightarrow c + d$, we have to distinguish three different situations, in which the braiding of two operators might produce:

1. $-S_{ab}^{cd}(\theta_a, \theta_b)$: describing scattering before any particle has hit the wall;
2. $0S_{ab}^{cd}(\theta_a, \theta_b)$: describing scattering after one particle has hit the wall;
3. $+S_{ab}^{cd}(\theta_a, \theta_b)$: describing scattering after both particles have hit the wall.

In $0S$, it is the particle with negative rapidity, which has scattered off the wall. Notice that the wall breaks translational invariance, so that the $S$ -matrices will not depend only on the difference of rapidities. In particular $0S$ is in general a function of the sum of the rapidities $\tilde{\theta}_{ab} := \theta_a + \theta_b$.

### 3 Factorization equations

We now use the associativity of the previous algebra to derive consistency conditions. Let us therefore consider the scattering of particles labelled by quantum numbers $a, b \ldots$, with rapidities $\theta_a, \theta_b \ldots$ in the presence of a reflecting wall, which we locate for convenience at rapidity $\theta = 0$. We start from a state with $\theta_a > \theta_b$, then

$$Z_a(\theta_a)Z_b(\theta_b)Z_w(0) = -S_{ab}^{a_1b_1}(\theta_{ab})Z_{a_1}(\theta_a)Z_{b_1}(\theta_b)Z_{w}(0)$$

$$= -S_{ab}^{a_1b_1}(\theta_{ab})W_{a_1}^{\tilde{\alpha}_1}(\theta_{a_1})Z_{b_1}(\theta_b)Z_{\tilde{\alpha}_1}(\tilde{\theta}_a)Z_{w}(0)$$

$$= -S_{ab}^{a_1b_1}(\tilde{\theta}_{ab})W_{a_1}^{\tilde{\alpha}_1}(\theta_{a_1})W_{b_1}^{\tilde{\alpha}_2}(\tilde{\theta}_{b_1})Z_{a_2}(\tilde{\theta}_a)Z_{b_2}(\theta_b)Z_{w}(0)$$

$$= -S_{ab}^{a_1b_1}(\theta_{ab})W_{a_1}^{\tilde{\alpha}_1}(\theta_{a_1})W_{b_1}^{\tilde{\alpha}_2}(\tilde{\theta}_{b_1})Z_{a_2}(\tilde{\theta}_a)Z_{b_2}(\theta_b)Z_{w}(0).$$

As in the derivation of the Yang-Baxter equation, factorization now implies that the order in which the particles scatter is irrelevant too. If we go through the same
steps, but scatter particle $b$ first from the wall, we derive the following identity:

$$-S_{ab}^{a_1b_1}(\theta_{ab})W_{a_1}^{\tilde{a}_1}(\theta_{a})S_{b_1\tilde{b}_1}(\tilde{\theta}_{b_1a_1})W_{b_2}^{\tilde{b}_2}(\theta_{b}) = W_{a}^{\tilde{a}}(\theta_{a})S_{ab}^{a_1b_1}(\tilde{\theta}_{ab})W_{a_1}^{\tilde{a}_1}(\theta_{a})S_{b_1\tilde{b}_1}(\tilde{\theta}_{b_1a_1})S_{ab}^{a_2b_2}(\theta_{ab}).$$

(3.7)

Diagramatically this corresponds to the equation in figure 1.

The presence of the wall breaks parity invariance, which - if true - would demand $S_{ab}(\theta) = S_{ba}(\theta)$. But restrictions of this kind can be generated, following the argumentation originally due to Cherednik [3, 4]. In the limit, when the rapidity of one of the particles vanishes, it is impossible to decide, whether it has or has not hit the wall before scattering off another particle. This imposes the additional conditions:

$$W_{a}^{\tilde{a}}(0) + S_{ba}^{b_1\tilde{b}_1}(\theta_{b_1a_1}) = 0, \quad W_{a}^{\tilde{a}}(0)S_{ba}^{b_1\tilde{b}_1}(\theta_{b_1a_1}) = -S_{ab}^{a_1b_1}(\theta_{ab})W_{a_1}^{\tilde{a}_1}(0).$$

(3.8)

To complete the scheme, we still have to consider 3-particle scattering. However, if equ. (3.7) is satisfied, we can always arrange rapidities, such that at all particles scatter against each other, before (or after) they hit the wall. Therefore factorization requires $\pm S(\theta)$ to satisfy in addition to the usual Yang-Baxter equations

$$\pm S_{\tilde{a}\tilde{b}}^{a'b'}(\theta_{ab}) \pm S_{ac}^{a_1c}(\theta_{ac}) \pm S_{bc}^{\tilde{b}c}(\theta_{bc}) = \pm S_{\tilde{b}c}^{a'b'}(\theta_{bc}) \pm S_{ac}^{a_1c}(\theta_{ac}) \pm S_{ab}^{a\tilde{b}}(\theta_{ab}).$$

(3.9)

These equations are sufficient to determine the $S$- and $W$-matrices, unless they are diagonal. In this case (3.7) are trivially satisfied and we require more information to determine them. Once an S-matrix possesses a pole due to the propagation of a bound state particle, one can formulate the so-called

4 Bootstrap equations

For simplicity we will in the sequel consider only diagonal $S, W$-matrices:

$$W_{a}^{b}(\theta) = \delta_{a}^{b}W_{a}(\theta)$$

(4.10)
and similarly for the $S$-matrices. In this case equs. (3.7) and (3.8) are satisfied, if

$$0 S_{ba}(\theta) = 0 S_{ab}(\theta) = - S_{ab}(\theta) = + S_{ba}(\theta) = - S_{ba}(\theta) = + S_{ab}(\theta).$$

(4.11)

Here we used unitarity equ. (2.5), which implies $W(0)^2 = 1$. Equ. (4.11) includes constraints usually coming from parity invariance. As a result of this equation we shall not distinguish anymore in the following between $- S, 0 S, + S$ and solely refer to them as $S$.

When particle $c$ is a bound state of particles $a$ and $b$ one assumes in addition to the Zamolodchikov algebra the validity of an operator product expansion involving the operators representing those particles

$$Z_a\left(\theta + i\eta_{i\alpha c}^b + \frac{i\varepsilon}{2}\right) Z_b\left(\theta - i\eta_{i\beta c}^a - \frac{i\varepsilon}{2}\right) = \frac{i\Gamma_{ij}^c Z_c(\theta)}{\varepsilon},$$

(4.12)

where $\Gamma_{ij}^c$ denotes the three particle vertex on mass-shell and $\eta_{i\alpha b}$ are the so-called fusing angles. Then multiplying this equation by $Z_d(\theta_d)$, using equation (2.1) and taking the limit $\varepsilon \to 0$ leads to a nontrivial consistency condition, which is known as the bootstrap equation [?]

$$S_{dc}(\theta) = S_{da}(\theta - i\eta_{i\alpha c}^b) S_{db}(\theta + i\eta_{i\beta c}^a).$$

(4.13)

It states that scattering particle $d$ against $c$ is equivalent to scatter $d$ against the bound state $a+b$. Evidently there has to be an equation of this kind in the presence of reflecting boundaries. Thus let us scatter particles $a, b$ and $d$ with rapidities $\theta_0 + i\eta_{i\alpha c}^b + \frac{i\varepsilon}{2}, \theta_0 - i\eta_{i\beta c}^a - \frac{i\varepsilon}{2}, \theta_d > 0$. We obtain by the same procedure as in the previous subsection

$$Z_a\left(\theta_0 + i\eta_{i\alpha c}^b + \frac{i\varepsilon}{2}\right) Z_b\left(\theta_0 - i\eta_{i\beta c}^a - \frac{i\varepsilon}{2}\right) Z_d(\theta_d) Z_w(0) = S_{ab}\left(2\theta_0 + i\eta_{i\alpha c}^b - i\eta_{i\beta c}^a\right)$$

$$S_{ad}\left(\theta_0d + i\eta_{i\alpha c}^b + \frac{i\varepsilon}{2}\right) S_{bd}\left(\theta_0d - i\eta_{i\beta c}^a - \frac{i\varepsilon}{2}\right) S_{ad}\left(\theta_0d + i\eta_{i\alpha c}^b + \frac{i\varepsilon}{2}\right)$$

$$S_{bd}\left(\bar{\theta}_0d - i\eta_{i\beta c}^a - \frac{i\varepsilon}{2}\right) W_a\left(\theta_a + i\eta_{i\alpha c}^b + \frac{i\varepsilon}{2}\right) W_b\left(\theta_b - i\eta_{i\beta c}^a - \frac{i\varepsilon}{2}\right) W_d(\theta_d)$$

$$Z_b\left(-\theta_0 + i\eta_{i\beta c}^a + \frac{i\varepsilon}{2}\right) Z_a\left(-\theta_0 - i\eta_{i\alpha c}^b - \frac{i\varepsilon}{2}\right) Z_d(-\theta_d) Z_w(0).$$
On the other hand multiplying equation (4.12) by $Z_d(\theta_d)Z_w(0)$ and performing similar operations we derive after taking the limit $\varepsilon \to 0$, the bootstrap equation in the presence of the wall

$$S_{dc}(\theta_{0d}) S_{dc}(\tilde{\theta}_{0d}) W_c(\theta_c) = W_a(\theta_a + i\eta_{ac}^b) W_b(\theta_b - i\eta_{bc}^a)$$

(4.14)

$$S_{ab}(2\theta_0 + i\eta_{ac}^b) S_{ad}(\theta_{0d} + i\eta_{ac}^b) S_{bd}(\theta_{0d} - i\eta_{bc}^a) S_{ad}(\tilde{\theta}_{0d} + i\eta_{ac}^b) S_{bd}(\tilde{\theta}_{0d} - i\eta_{bc}^a).$$

Diagrammatically we depict this situation in figure 2. Since the scattering matrix satisfies the conventional bootstrap equation (4.13), our equation for $W$ reduces to

$$W_c(\theta) = W_a(\theta + i\eta_{ac}^b) W_b(\theta - i\eta_{bc}^a) S_{ab}(2\theta + i\eta_{ac}^b - i\eta_{bc}^a)$$

(4.15)

which we call, due to the presence of the factor $S_{ab}(2\theta_0 + i\eta_{ac}^b - i\eta_{bc}^a)$, an inhomogeneous bootstrap equation.

The equations (3.7) and (4.14) also solve the analogous problem of factorized scattering in the presence of two walls, since the two walls do not interfere with each other.

## 5 The $W$-matrix

In this section, we shall discuss the solutions of the coupled equs. (4.13). The two particle scattering matrices to be used in this paper always factorize into the form $S(\theta) = \prod_x \{x\}_\theta$. Adopting our notation from [8], each of this block reads

$$\{x\}_\theta := \frac{[x]_\theta}{[-x]_\theta},$$

(5.16)

with

$$[x]_\theta := \frac{\langle x + 1 \rangle_\theta \langle x - 1 \rangle_\theta}{\langle x + 1 - B \rangle_\theta \langle x - 1 + B \rangle_\theta}$$

(5.17)

and

$$\langle x \rangle_\theta := \sinh \frac{1}{2} \left( \theta + \frac{i\pi x}{\hbar} \right).$$

(5.18)
B is a function, which takes its values between 0 and 2 containing the dependence on the coupling constant $\beta$ of the Lagrangian field theory. $h$ denotes the Coxeter number of the underlying Lie algebra of the theory. The S-matrices possess furthermore the property to be invariant under $B \rightarrow 2 - B$, that is under an interchange of the strong and weak coupling regime.

Alternatively each block is equivalent to the following integral representation

$$\{x\}_{\theta} = \exp \left( \int_0^\infty \frac{dt}{t \sinh t} f_{x,B}(t) \sinh \frac{\theta t}{i\pi} \right)$$

(5.19)

where

$$f_{x,B}(t) = 8 \sinh \frac{tB}{2h} \sinh \frac{t}{h} \left( 1 - \frac{B}{2} \right) \sinh t \left( 1 - \frac{x}{h} \right).$$

(5.20)

Whilst (5.19) nicely exhibits the polestructure of the S-matrix, equation (5.19) is sometimes more useful for explicit evaluations and we shall require this form below.

We might now expect that the $W$-matrix factorizes in an analogous fashion into blocks as the S-matrix. Indeed we find a one-to-one correspondence between the blocks of the $W$- and $S$-matrix:

$$W(\theta) = \prod_x W_x(\theta).$$

(5.21)

Similar as the S-matrix, the $W$-matrix factorizes further into subblocks

$$W_x(\theta) = \frac{w_{1-x}(\theta)w_{-1-x}(\theta)}{w_{1-x-B}(\theta)w_{-1-x+B}(\theta)}.$$  

(5.22)

As demanded by the unitarity (2.3) of the $W$-matrix we have

$$w_x(\theta)w_x(-\theta) = 1.$$  

(5.23)

Furthermore we shall verify the relations

$$w_{x-2h}(\theta)w_{-x}(\theta) = 1$$

(5.24)

$$w_x(0) = w_{-h}(\theta) = 1$$

(5.25)

$$w_x \left( \theta + \frac{iy\pi}{2h} \right)w_x \left( \theta - \frac{iy\pi}{2h} \right) = w_{x+y}(\theta)w_{x-y}(\theta)$$

(5.26)

$$w_x(\theta + i\pi) = \eta_x(\theta)w_x(\theta)$$

(5.27)
where the function \( \eta_x(\theta) \) satisfies individually the homogeneous bootstrap equation

\[
\eta_x(\theta + i \eta_{ab}^b) \eta_x(\theta - i \eta_{ab}^a) = \eta_x(\theta) .
\]  
\( (5.28) \)

Notice that \( \eta_x(\theta) \) does not contain any poles in the physical sheet \( 0 < \theta < i\pi \). All blocks converge to one in the asymptotic limit \( \theta \rightarrow 0 \), resulting from

\[
\lim_{\theta \rightarrow \infty} w_x(\theta) = 1 .
\]  
\( (5.29) \)

It turns out that the function \( w_x(\theta) \) possesses neither poles nor zeros in the physical strip, such that no particle creation and absorption takes place in the wall. The absence of the poles and zeroes was expected from the assumption that the scattering off the wall takes place in an elastic fashion.

We shall now compute some explicit examples of the \( W \)-matrix, starting with the

5.1 The Bullough-Dodd model

The BD-model \cite{BD} ( \( A_2^{(2)} \)-affine Toda theory ) represents an integrable quantum field theory involving one type of scalar field only, which satisfies a relativistically invariant equation in two dimensions. The model is ideal to illustrate the general principles presented in the previous sections, since the particle, say \( A \), emerges as a bound state of itself, i.e. \( A + A \rightarrow A \) is possible. Its classical Lagrangian is obtainable from a folding \cite{BD} of the \( D_4^{(1)} \)-affine Toda theory, where the three roots corresponding to the degenerate particles and the negative of the highest root are identified. The resulting Dynkin diagram is the simplest example of a non-simply laced one, containing the root \( \alpha \), which is related to the scalar field, whose square length equals two and the root \( \alpha_0 = -2\alpha \), whose square length is consequently eight. Then its classical Lagrangian density reads

\[
\mathcal{L} = \frac{1}{2} \partial_{\mu} \phi \partial^{\mu} \phi - \frac{m^2}{\beta^2} \left( 2e^{\beta \phi} + e^{-2\beta \phi} \right) ,
\]  
\( (5.30) \)
where \( m \) denotes the bare mass and \( \beta \) the coupling constant, which we assume to be real to avoid the presence of solitons. For more details on the model we refer to [12] and the references therein, but here we mainly want state the main properties we are going to employ. The scattering matrix can be obtained by the above folding procedure and it turns out to be

\[
S^{BD}(\theta) = \{1\}_\theta \{2\}_\theta .
\]

(5.31)

The Coxeter number of the BD-model equals three.

The scattering matrix satisfies the homogeneous bootstrap equation in the form

\[
S^{BD}(\theta) = S^{BD}(\theta + \omega) \ S^{BD}(\theta - \omega) ,
\]

(5.32)

with \( \omega = \frac{i\pi}{3} \) and consequently the inhomogeneous bootstrap equation acquires the form

\[
W(\theta) = W(\theta + \omega) \ W(\theta - \omega) \ S^{BD}(2\theta) .
\]

(5.33)

Employing now Fourier transforms after taking the logarithm to solve such equations, we obtain

\[
W(\theta) = \exp\left( \int d\theta' \ G(\theta - \theta') \ln S(2\theta') \right) ,
\]

(5.34)

where the Green function \( G \) is given by

\[
G(\theta) = \lim_{\eta \uparrow 1} \frac{1}{\omega \sqrt{3}} \ \frac{\sinh \left( \frac{2\pi}{3\omega} \left( \frac{\theta}{\eta} \right) \right)}{\sinh \left( \frac{\pi}{3} \left( \frac{\theta}{\eta} \right) \right)} .
\]

(5.35)

The introduction of the parameter \( \eta \) is necessary to guarantee the convergence of the Fourier transform. Employing now the integral representation for the blocks of the \( S \)-matrix \((5.19)\), we are lead to a factorization of the form \((5.21)\) and \((5.22)\), where each of the sublocks \( w_x(\theta) \) is given by the integral representation

\[
w_x(\theta) = \exp\left( \int_0^\infty dt \ t \sinh t \ \frac{2 \sinh \left( 1 + \frac{2}{\pi} t \right) \ \frac{2t}{\pi}}{1 - 2 \ \cosh \frac{2t}{\pi}} \right) .
\]

(5.36)
Solving the integral we obtain

\[ w_x(\theta) = \prod_{l=0}^{\infty} \left( \frac{\Gamma\left(1 + (l + 1)\frac{\omega}{\pi} + \frac{x}{2h} + \frac{i\theta}{\pi}\right) \Gamma\left((l + 1)\frac{\omega}{\pi} - \frac{x}{2h} - \frac{i\theta}{\pi}\right)}{\Gamma\left((l + 1)\frac{\omega}{\pi} - \frac{x}{2h} + \frac{i\theta}{\pi}\right) \Gamma\left(1 + (l + 1)\frac{\omega}{\pi} + \frac{x}{2h} - \frac{i\theta}{\pi}\right)} \right)^{\frac{\sin((l+1)\omega)}{\sin \omega}}. \]  

This equation exhibits nicely the pole structure of \( w_x(\theta) \), and therefore \( W(\theta) \), and can be used to prove the functional identities (5.23) - (5.29). The function \( \eta(\theta) \), which results as a shift of \( i\pi \) in equation (5.27) takes on the form

\[ \eta_x(\theta) = \prod_{l=0}^{\infty} \left( \frac{(l + 1)\frac{\omega}{\pi} - \frac{x}{2h} - \frac{i\theta}{\pi}}{(l + 1)\frac{\omega}{\pi} + \frac{x}{2h} + \frac{i\theta}{\pi}} \right)^{\frac{\sin((l+1)\omega)}{\sin \omega}} \]  

and satisfies individually the homogeneous bootstrap equation

\[ \eta_x(\theta + i\omega) \eta_x(\theta - i\omega) = \eta_x(\theta). \]  

\( \eta_x(\theta) \) does not posses any poles in the physical sheet. Furthermore we derive from (5.37) the functional equation

\[ w_x(\theta + i\omega) \; w_x(\theta - i\omega) = w_x(\theta)^{\langle x \rangle_{-2\theta}/\langle x \rangle_{2\theta}} \]  

from which we infer the crucial identity for the blocks of the W-matrix

\[ \mathcal{W}_x(\theta) = \mathcal{W}_x(\theta + i\omega) \; \mathcal{W}_x(\theta - i\omega)^{\{x\}_{2\theta}}. \]  

This equation demonstrates explicitly that the factorization of \( W \) occurs in a one-to-one fashion with respect to the factorization of the S-matrix and we finally obtain the solution for the \( W \)-matrix of the Bullough-Dodd model

\[ W(\theta) = \mathcal{W}_1(\theta)\mathcal{W}_2(\theta). \]  

Notice that this function posses neither poles nor zeros in the physical sheet.
5.2 The $A_2^{(1)}$-affine Toda theory

The $A_2^{(1)}$-affine Toda theory is the most simple example of an affine Toda theory \[13, 14\] involving more than one particle. It contains two particles of equal masses which are conjugate to each other, that is choosing complex scalar fields we have $\phi_1^* = \phi_2$. Its classical Lagrangian density

$$
\mathcal{L} = \frac{1}{2} \partial_{\mu} \phi \partial^{\mu} \phi - \frac{m^2}{\beta^2} \left( e^{\beta \sqrt{2} \phi_2} + e^{\beta \sqrt{3} (\sqrt{3} \phi_1 - \phi_2)} + e^{-\beta \sqrt{3} (\sqrt{3} \phi_1 + \phi_2)} \right)
$$

possesses a $\mathbb{Z}_3$-symmetry, in the sense that it is left invariant under the transformation

$$
\phi \rightarrow \begin{pmatrix} e^{\frac{2\pi i}{3} n} \\ e^{\frac{4\pi i}{3} n} \end{pmatrix} \phi \quad n = 1, 2, 3.
$$

From the three point couplings, which turn out to be $C_{111} = -C_{222} = -i3\beta m^2$ and $C_{112} = C_{221} = 0$ or the application of the fusing rule of affine Toda theory \[13, 16, 8, 17\] we obtain that the following processes are permitted

$$
V_1 + V_1 \rightarrow V_2 = V_1 \quad (5.45)
$$
$$
V_2 + V_2 \rightarrow V_1 = V_2 \quad (5.46)
$$

where we denote the particles by $V_i$ with $i = 1, 2$. The scattering matrices are given by

$$
S_{11}(\theta) = S_{22}(\theta) = \{1\}_\theta 
$$
$$
S_{12}(\theta) = \{2\}_\theta.
$$

Here the blocks are again of the form (5.16) with $h = 3$. Where $S_{11}(\theta) = S_{22}(\theta)$ have poles at $\frac{2\pi i}{3}$ describing the processes (5.43) and (5.46), whereas $S_{12}(\theta)$ has no poles in the physical sheet. Furthermore, the scattering matrix satisfies the bootstrap equations

$$
S_{12}(\theta) = S_{11}(\theta + i\omega)S_{11}(\theta - i\omega) 
$$
$$
S_{11}(\theta) = S_{12}(\theta + i\omega)S_{12}(\theta - i\omega)
$$
for \( l = 1, 2, \omega = i\pi/3 \), together with the crossed versions of this. Since the scattering matrices involved satisfy the ordinary bootstrap equations, the wall bootstrap equations reduce to

\[
\begin{align*}
W_2(\theta) &= W_1(\theta + i\omega) W_1(\theta - i\omega) S_{11}(2\theta) \quad \text{(5.51)} \\
W_1(\theta) &= W_2(\theta + i\omega) W_2(\theta - i\omega) S_{22}(2\theta) \quad \text{(5.52)}
\end{align*}
\]

Together with equation (5.41) we notice that these equations are solved by

\[
W_1(\theta) = W_2(\theta) = W_1(\theta) \quad \text{(5.53)}
\]

Again \( W(\theta) \) introduces no poles nor zeros in the physical sheet. The fact that \( W_1(\theta) \) equals \( W_2(\theta) \) is a consequence of the mass degeneracy of the theory, which is reflected by the automorphism of the Dynkin diagram [10, 11]. The folding towards the Bullough-Dodd model introduces an additional block in the \( W \)-matrix, due to the identification of particle 1 and 2, in a similar fashion as for the \( S \)-matrix.

### 5.3 The \( A_4^{(2)} \)-affine Toda theory

The \( A_4^{(2)} \)-affine Toda theory is the most simple example of an affine Toda theory, where the roots associated to the particles are connected by more than one lace on the Dynkin diagram. It describes two self-conjugate real scalar fields whose classical mass ratio is \( m_1^2 = (5 - \sqrt{5})/(5 + \sqrt{5})m_2^2 \). The roots involved in this theory might be constructed from a \( D_6^{(1)} \)-affine Dynkin diagram, where the four roots forming the two handles and the two roots which are connected to the handles are identified.

The resulting roots are

\[
\alpha_1 = -\frac{2\sqrt{2}}{\sqrt{5}} \left( \sin \frac{2\pi}{5}, \sin \frac{\pi}{5} \right) \quad \text{and} \quad \alpha_2 = \frac{4\sqrt{2}}{\sqrt{5}} \left( \sin \frac{\pi}{5} \cos \frac{2\pi}{5}, \sin \frac{2\pi}{5} \cos \frac{\pi}{5} \right) \quad \text{(5.54)}
\]
where the root corresponding to the affinisation $\alpha_0$ is the negative of twice the sum of this two roots. In terms of this vectors the Lagrangian density reads

$$L = \frac{1}{2} \partial_{\mu} \phi \partial^{\mu} \phi - \frac{m^2}{\beta^2} \left( e^{\beta \alpha_0 \cdot \phi} + 2 e^{\beta \alpha_1 \cdot \phi} + 2 e^{\beta \alpha_2 \cdot \phi} \right), \quad (5.55)$$

from which we may compute the three point couplings $C_{111} = C_{222} = 0$ and $C_{221} \neq 0$, $C_{112} \neq 0$ such that the following fusing processes are possible

$$V_1 + V_1 \rightarrow V_2 \quad (5.56)$$
$$V_2 + V_2 \rightarrow V_1 \quad (5.57)$$
$$V_1 + V_2 \rightarrow V_1 + V_2. \quad (5.58)$$

The corresponding scattering matrices turn out to be

$$S_{11}(\theta) = \{1\}_\theta \{4\}_\theta \quad (5.59)$$
$$S_{12}(\theta) = \{2\}_\theta \{3\}_\theta \quad (5.60)$$
$$S_{22}(\theta) = \{1\}_\theta \{2\}_\theta \{3\}_\theta \{4\}_\theta. \quad (5.61)$$

The Coxeter number $h$ is five in this case. Here $S_{11}(\theta)$ has a single pole with negative residue at $\frac{3\pi i}{5}$ and one with positive residue at $\frac{2\pi i}{5}$ describing the process (5.56). $S_{12}(\theta)$ has single poles with negative residues at $\frac{\pi i}{5}$, $\frac{2\pi i}{5}$ and single poles with positive residue at $\frac{3\pi i}{5}$, $\frac{4\pi i}{5}$ corresponding to (5.58). $S_{22}(\theta)$ has a single pole with negative residue at $\frac{\pi i}{5}$, a single pole with positive residue at $\frac{4\pi i}{5}$ related the the fusing (5.57) and double poles at $\frac{2\pi i}{5}$, $\frac{3\pi i}{5}$. The bootstrap equation are in this case

$$S_{l2}(\theta) = S_{l1}(\theta + i\omega)S_{l1}(\theta - i\omega) \quad (5.62)$$
$$S_{l1}(\theta) = S_{l2}(\theta + i\omega)S_{l2}(\theta - i\omega) \quad (5.63)$$
$$S_{l1}(\theta) = S_{l1}(\theta + 3i\omega)S_{l2}(\theta + i\omega) \quad (5.64)$$
$$S_{l2}(\theta) = S_{l2}(\theta - i\omega)S_{l1}(\theta + 2i\omega) \quad (5.65)$$

with $l = 1, 2$. Because of the previous equations, the wall bootstrap equations reduce to

$$W_2(\theta) = W_1(\theta + i\omega) W_1(\theta - i\omega) S_{l1}(2\theta) \quad (5.66)$$

13
\[ W_1(\theta) = W_2(\theta + i\omega) W_2(\theta - i\omega) S_{22}(2\theta) \] 
\[ W_1(\theta) = W_2(\theta + i\omega) W_1(\theta - 3i\omega) S_{12}(2\theta) \] 
\[ W_2(\theta) = W_1(\theta + 2i\omega) W_2(\theta - i\omega) S_{12}(2\theta) \]  
\[ (5.67) \]
\[ (5.68) \]
\[ (5.69) \]

Introducing the notation \( W_{11}(\theta) := W_1(\theta) \), \( W_{22}(\theta) := W_2(\theta) \) and \( W_{12}(\theta) := W_2(\theta)/W_1(\theta) \), these equations decouple and we are left with the problem to solve
\[ W_{ij}(\theta) = W_{ij}(\theta + i\omega) W_{ij}(\theta - i\omega) W_{ij}(\theta + 3i\omega) W_{ij}(\theta - 3i\omega) S_{ij}(2\theta) \]  
\[ (5.70) \]

Again we utilise Fourier transforms after taking the logarithm and obtain
\[ W_{ij}(\theta) = \exp \left( \int d\theta' G(\theta - \theta') \ln S_{ij}(2\theta') \right) \]  
\[ (5.71) \]

where the Green function \( G(\theta) \) in this case is given by
\[ G(\theta) = \lim_{\eta \to 1} \frac{1}{\omega \sinh \frac{\pi \eta}{\omega}} \left( \frac{\sinh \left( \frac{\pi}{2\omega}(\theta)\eta \right)}{\sin \frac{2\pi}{3}} + \frac{\sinh \left( \frac{4\pi}{5\omega}(\theta)\eta \right)}{\sin \omega + 3 \sin 3\omega} + \frac{\sinh \left( \frac{2\pi}{\omega}(\theta)\eta \right)}{\sin 3\omega + 3 \sin 9\omega} \right) \]  
\[ (5.72) \]

Employing now again the integral representation for the S-matrix we obtain the following integral representation for the building blocks of the W-matrix
\[ w_x(\theta) = \exp \left( I_{\frac{2x}{3}}(\theta) + I_{\omega}(\theta) + I_{3\omega}(\theta) \right) \]  
\[ (5.73) \]

where
\[ I_a(\theta) = \frac{1}{5 - 6 \sin^2 a} \int_0^\infty dt \frac{2 \sin \left( 1 + \frac{x}{\pi} \right) t \sin \frac{2\eta t}{\pi}}{\sin a - 2 \cosh \frac{2\omega}{\pi}} \]  
\[ (5.74) \]

Solving the integral gives
\[ w_x(\theta) = \prod_{l=0}^{\infty} \frac{\Gamma \left( 1 + (l + 1)\frac{\omega}{\pi} + \frac{x}{2h} + \frac{i\eta}{\pi} \right)}{\Gamma \left( (l + 1)\frac{\omega}{\pi} - \frac{x}{2h} + \frac{i\eta}{\pi} \right)} \]  
\[ (5.75) \]

with
\[ P_l = \frac{\sin \left( (l + 1)\frac{2\pi}{3} \right)}{\sin \left( \frac{\pi}{3} \right)} + \frac{\sin \left( (l + 1)\frac{\pi}{5} \right)}{2 \sin \left( \frac{\pi}{5} \right) \left( 5 - 6 \sin^2 \left( \frac{\pi}{5} \right) \right)} + \frac{\sin \left( (l + 1)\frac{3\pi}{5} \right)}{2 \sin \left( \frac{3\pi}{5} \right) \left( 5 - 6 \sin^2 \left( \frac{3\pi}{5} \right) \right)} \]  
\[ (5.76) \]
Again this equation is useful to extract the polestructure and to prove the identities (5.23) - (5.29). The function $\eta_x(\theta)$ is now given by

$$
\eta_x(\theta) = \prod_{l=0}^{\infty} \left( \frac{\left((l+1)\frac{\omega}{\pi} - \frac{x}{2h} - \frac{i\theta}{\pi}\right) \left(-1 + (l+1)\frac{\omega}{\pi} + \frac{x}{2h} + \frac{i\theta}{\pi}\right)}{\left(1 + (l+1)\frac{\omega}{\pi} + \frac{x}{2h} - \frac{i\theta}{\pi}\right) \left((l+1)\frac{\omega}{\pi} + \frac{x}{2h} + \frac{i\theta}{\pi}\right)} \right)^{P_l}, \tag{5.77}
$$

satisfying the homogeneous bootstrap equation and having no poles in the physical sheet. Further we derive the relation

$$
 w_x(\theta + i\omega) w_x(\theta - i\omega) w_x(\theta + 3i\omega) w_x(\theta - 3i\omega) = \frac{\langle x \rangle_{2\theta}}{\langle x \rangle_{2\theta}} \tag{5.78}
$$

from which we deduce

$$
 W_{ij_x}(\theta) = W_{ij_x}(\theta + i\omega) W_{ij_x}(\theta - i\omega) W_{ij_x}(\theta + 3i\omega) W_{ij_x}(\theta - 3i\omega) \langle x \rangle_{2\theta}. \tag{5.79}
$$

Comparison with equation (5.71) now demonstrates that the $W$-matrix again factorizes in a one-to-one fashion with respect to the scattering matrix and we finally obtain the $W$-matrix for the $A_2^{(1)}$-affine Toda theory

$$
 W_1(\theta) = W_1 W_4 \tag{5.80}
$$

$$
 W_2(\theta) = W_1 W_2 W_3 W_4 \tag{5.81}
$$

From the property of the function $w_x(\theta)$ we note again that the physical sheet is free of singularities.

### 6 Conclusions

We have demonstrated how to formulate factorization equations and in particular the inhomogeneous bootstrap equations by employing an extended version of Zamolodchikov's algebra. Whereas in the absence of reflecting boundaries such equations could be utilised to construct the two particle scattering matrix, now they are sufficient to determine the $W$-matrix, which encodes the scattering of a particle off the wall. For all cases investigated $W(\theta)$ does posses neither poles nor
zeros in the physical sheet, such that the wall does not create or absorb any par-
ticles. This feature is made transparent by expressing $W(\theta)$ as infinite products of $\Gamma$
functions. Actually the structure is very similar to the one found for the minimal
two-particle form factors $F(\theta)$ \[18, 12\].
