UBIQUITY IN GRAPHS II: UBIQUITY OF GRAPHS WITH NON-LINEAR END STRUCTURE

NATHAN BOWLER, CHRISTIAN ELBRACHT, JOSHUA ERDE, PASCAL GOLLIN, KARL HEUER, MAX PITZ, AND MAXIMILIAN TEEGEN

ABSTRACT. A graph $G$ is said to be $\preceq$-ubiquitous, where $\preceq$ is the minor relation between graphs, if whenever $\Gamma$ is a graph with $nG \preceq \Gamma$ for all $n \in \mathbb{N}$, then one also has $\aleph_0 G \preceq \Gamma$, where $\alpha G$ is the disjoint union of $\alpha$ many copies of $G$. A well-known conjecture of Andreae is that every locally finite connected graph is $\preceq$-ubiquitous.

In this paper we give a sufficient condition on the structure of the ends of a graph $G$ which implies that $G$ is $\preceq$-ubiquitous. In particular this implies that the full grid is $\preceq$-ubiquitous.

§1. INTRODUCTION

This paper is the second in a series of papers making progress towards a conjecture of Andreae on the ubiquity of graphs. Given a graph $G$ and some relation $\triangleleft$ between graphs we say that $G$ is $\triangleleft$-ubiquitous if whenever $\Gamma$ is a graph such that $nG \triangleleft \Gamma$ for all $n \in \mathbb{N}$, then $\aleph_0 G \triangleleft \Gamma$, where $\alpha G$ denotes the disjoint union of $\alpha$ many copies of $G$. For example, a classic result of Halin [9] says that the ray is $\subseteq$-ubiquitous, where $\subseteq$ is the subgraph relation.

Examples of graphs which are not ubiquitous with respect to the subgraph or topological minor relation are known (see [2] for some particularly simple examples). In [1] Andreae initiated the study of ubiquity of graphs with respect to the minor relation $\preceq$. He constructed a graph which is not $\preceq$-ubiquitous, however the construction relied on the existence of a counterexample to the well-quasi-ordering of infinite graphs under the minor relation, for which only examples of very large cardinality are known [13]. In particular, the question of whether there exists a countable graph which is not $\preceq$-ubiquitous remains open. Most importantly, however, Andreae [1] conjectured that at least all locally finite graphs, those with all degrees finite, should be $\preceq$-ubiquitous.

The Ubiquity Conjecture. Every locally finite connected graph is $\preceq$-ubiquitous.

In [2] Andreae proved that his conjecture holds for a large class of locally finite graphs. The exact definition of this class is technical, but in particular his result implies the following.
Theorem 1.1 (Andreae, [2, Corollary 2]). Let $G$ be a connected, locally finite graph of finite tree-width such that every block of $G$ is finite. Then $G$ is $\preceq$-ubiquitous.

Note that every end in such a graph $G$ must have degree\(^1\) one.

Andreae’s proof employs deep results about well-quasi-orderings of labelled (infinite) trees [12]. Interestingly, the way these tools are used does not require the extra condition in Theorem 1.1 that every block of $G$ is finite and so it is natural to ask if his proof can be adapted to remove this condition. And indeed, it is the purpose of the present and subsequent paper in our series, [3], to show that this is possible, i.e. that all connected, locally finite graphs of finite tree-width are $\preceq$-ubiquitous.

\[\begin{figure}
\centering
\includegraphics{linkage.png}
\caption{A linkage between $\mathcal{R}$ and $\mathcal{S}$.}
\end{figure}\]

The present paper lays the groundwork for this extension of Andreae’s result. The fundamental obstacle one encounters when trying to extend Andreae’s methods is the following: Let $[n] = \{1, 2, \ldots, n\}$. In the proof we often have two families of disjoint rays $\mathcal{R} = (R_i : i \in [n])$ and $\mathcal{S} = (S_j : j \in [m])$ in $\Gamma$, which we may assume all converge\(^1\) to a common end of $\Gamma$, and we wish to find a linkage between $\mathcal{R}$ and $\mathcal{S}$, that is, an injective function $\sigma : [n] \to [m]$ and a set $\mathcal{P}$ of disjoint finite paths $P_i$ from $x_i \in R_i$ to $y_{\sigma(i)} \in S_{\sigma(i)}$ such that the walks
\[\mathcal{T} = (R_i x_i P_i y_{\sigma(i)} S_{\sigma(i)} : i \in [n])\]
formed by following each $R_i$ along to $x_i$, then following the path $P_i$ to $y_{\sigma(i)}$, then following the tail of $S_{\sigma(i)}$, form a family of disjoint rays (see Figure 1.1). Broadly, we can think of
\[\footnote{A precise definitions of rays, the ends of a graph, their degree, and what it means for a ray to converge to an end can be found in Section 2.}\]
this as ‘re-routing’ the rays \( R \) to some subset of the rays in \( S \). Since all the rays in \( R \) and \( S \) converge to the same end of \( \Gamma \), it is relatively simple to show that, as long as \( n \leq m \), there is enough connectivity between the rays in \( \Gamma \) so that such a linkage always exists.

However, in practice it is not enough for us to be guaranteed the existence of some injection \( \sigma \) giving rise to a linkage, but instead we want to choose \( \sigma \) in advance, and be able to find a corresponding linkage afterwards.

In general, however, it is quite possible that for certain choices of \( \sigma \) no suitable linkage exists. Consider for example the case where \( \Gamma \) is the half grid (briefly denoted by \( \mathbb{Z} \square \mathbb{N} \)), which is the graph whose vertex set is \( \mathbb{Z} \times \mathbb{N} \) and where two vertices are adjacent if they differ in precisely one co-ordinate and the difference in that co-ordinate is one. If we consider two sufficiently large families of disjoint rays \( R \) and \( S \) in \( \Gamma \), then it is not hard to see that both \( R \) and \( S \) inherit a linear ordering from the planar structure of \( \Gamma \), which must be preserved by any linkage between them.

Analysing this situation gives rise to the following definition: We say that an end \( \epsilon \) of a graph \( G \) is linear if for every finite set \( R \) of at least three disjoint rays in \( G \) which converge to \( \epsilon \) we can order the elements of \( R \) as \( R = \{ R_1, R_2, \ldots, R_n \} \) such that for each \( 1 \leq k < i < \ell \leq n \), the rays \( R_k \) and \( R_\ell \) belong to different ends of \( G - V(R_i) \).

Thus the half grid has a unique end and it is linear. On the other end of the spectrum, let us say that a graph \( G \) has nowhere-linear end structure if no end of \( G \) is linear. Since ends of degree at most two are automatically linear, every end of a graph with nowhere-linear end structure must have degree at least three.

Our main theorem in this paper is the following.

**Theorem 1.2.** Every locally finite connected graph with nowhere-linear end structure is \( \prec \)-ubiquitous.

Roughly, if we assume that every end of \( G \) has nonlinear structure, then the fact that \( nG \preceq \Gamma \) for all \( n \in \mathbb{N} \) allows us to deduce that \( \Gamma \) must also have some end with a sufficiently complicated structure that we can always find suitable linkages for all \( \sigma \) as above. In fact, this property is so strong that we do not need to follow Andreae’s strategy for such graphs. We can use the linkages to directly build a \( K_{\aleph_0} \)-minor of \( \Gamma \), and it follows that \( \aleph_0G \preceq \Gamma \).

In later papers in the series, we shall need to make more careful use of the ideas developed here. We shall analyse the possible kinds of linkages which can arise between two families of rays converging to a given end. If some end of \( \Gamma \) admits many different kinds of linkages, then we can again find a \( K_{\aleph_0} \)-minor. If not, then we can use the results of the present paper to show that certain ends of \( G \) are linear. This extra structure allows us to carry out an argument like that of Andreae, but using only the limited collection of these maps.
σ which we know to be present. This technique will be key to extending Theorem 1.1 in [3].

Independently of these potential later developments, our methods already allow us to establish new ubiquity results for many natural graphs and graph classes.

As a first concrete example, let \( G \) be the full grid, a graph not previously known to be ubiquitous. The full grid (briefly denoted by \( \mathbb{Z} \square \mathbb{Z} \)) is analogously defined as the half grid but with \( \mathbb{Z} \times \mathbb{Z} \) as vertex set. The grid \( G \) is one-ended, and for any ray \( R \) in \( G \), the graph \( G - V(R) \) still has at most one end. Hence the unique end of \( G \) is non-linear, and so Theorem 1.2 has the following corollary:

**Corollary 1.3.** The full grid is \( \preceq \)-ubiquitous.

Using an argument similar in spirit to that of Halin [10], we also establish the following theorem in this paper:

**Theorem 1.4.** Any connected minor of the half grid \( \mathbb{N} \square \mathbb{Z} \) is \( \preceq \)-ubiquitous.

Since every countable tree is a minor of the half grid, Theorem 1.4 implies that all countable trees are \( \preceq \)-ubiquitous, see Corollary 7.4. We remark that while all trees are ubiquitous with respect to the topological minor relation, [5], the problem whether all uncountable trees are \( \preceq \)-ubiquitous has remained open, and we hope to resolve this in a paper in preparation [4].

In a different direction, if \( G \) is any locally finite connected graph, then it is possible to show that \( G \square \mathbb{Z} \) or \( G \square \mathbb{N} \) either have nowhere-linear end structure, or are a subgraph of the half grid respectively. Hence, Theorems 1.2 and 1.4 together have the following corollary.

**Theorem 1.5.** For every locally finite connected graph \( G \), both \( G \square \mathbb{Z} \) and \( G \square \mathbb{N} \) are \( \preceq \)-ubiquitous.

Finally, we will also show the following result about non-locally finite graphs. For \( k \in \mathbb{N} \), we let the \( k \)-fold dominated ray be the graph \( DR_k \) formed by taking a ray together with \( k \) additional vertices, each of which we make adjacent to every vertex in the ray. For \( k \leq 2 \), \( DR_k \) is a minor of the half grid, and so ubiquitous by Theorem 1.4. In our last theorem, we show that \( DR_k \) is ubiquitous for all \( k \in \mathbb{N} \).

**Theorem 1.6.** The \( k \)-fold dominated ray \( DR_k \) is \( \preceq \)-ubiquitous for every \( k \in \mathbb{N} \).

The paper is structured as follows: In Section 2 we introduce some basic terminology for talking about minors. In Section 3 we introduce the concept of a ray graph and linkages between families of rays, which will help us to describe the structure of an end.
In Sections 4 and 5 we introduce a pebble-pushing game which encodes possible linkages between families of rays and use this to give a sufficient condition for an end to contain a countable clique minor. In Section 6 we re-introduce some concepts from [5] and show that we may assume that the $G$-minors in $\Gamma$ are concentrated towards some end $\epsilon$ of $\Gamma$. In Section 7 we use the results of the previous section to prove Theorem 1.4 and finally in Section 8 we prove Theorem 1.2 and its corollaries.

§2. Preliminaries

In our graph theoretic notation we generally follow the textbook of Diestel [7]. Given two graphs $G$ and $H$ the cartesian product $G \square H$ is a graph with vertex set $V(G) \times V(H)$ with an edge between $(a,b)$ and $(c,d)$ if and only if $a = c$ and $(b,d) \in E(H)$ or $(a,c) \in E(G)$ and $b = d$.

**Definition 2.1.** A one-way infinite path is called a ray and a two-way infinite path is called a double ray.

For a path or ray $P$ and vertices $v,w \in V(P)$, let $vPw$ denote the subpath of $P$ with endvertices $v$ and $w$. If $P$ is a ray, let $Pv$ denote the finite subpath of $P$ between the initial vertex of $P$ and $v$, and let $vP$ denote the subray (or tail) of $P$ with initial vertex $v$.

Given two paths or rays $P$ and $Q$ which are disjoint but for one of their endvertices, we write $PQ$ for the concatenation of $P$ and $Q$, that is the path, ray or double ray $P \cup Q$. Moreover, if we concatenate paths of the form $vPw$ and $wQx$, then we omit writing $w$ twice and denote the concatenation by $vPwQx$.

**Definition 2.2** (Ends of a graph, cf. [7, Chapter 8]). An end of an infinite graph $\Gamma$ is an equivalence class of rays, where two rays $R$ and $S$ are equivalent if and only if there are infinitely many vertex disjoint paths between $R$ and $S$ in $\Gamma$. We denote by $\Omega(\Gamma)$ the set of ends of $\Gamma$.

We say that a ray $R \subseteq \Gamma$ converges (or tends) to an end $\epsilon$ of $\Gamma$ if $R$ is contained in $\epsilon$. In this case we call $R$ an $\epsilon$-ray.

Given an end $\epsilon \in \Omega(\Gamma)$ and a finite set $X \subseteq V(\Gamma)$ there is a unique component of $\Gamma - X$ which contains a tail of every ray in $\epsilon$, which we denote by $C(X, \epsilon)$.

For an end $\epsilon \in \Gamma$ we define the degree of $\epsilon$ in $\Gamma$ as the supremum of all sizes of sets containing vertex disjoint $\epsilon$-rays. If an end has finite degree, we call it thin. Otherwise, we call it thick.

A vertex $v \in V(\Gamma)$ dominates an end $\epsilon \in \Omega(\Gamma)$ if there is a ray $R \in \omega$ such that there are infinitely many $v - R$-paths in $\Gamma$ that are vertex disjoint except from $v$.

We will use the following two basic facts about infinite graphs.
Proposition 2.3. [7, Proposition 8.2.1] An infinite connected graph contains either a ray or a vertex of infinite degree.

Proposition 2.4. [7, Exercise 8.19] A graph $G$ contains a subdivided $K_{\aleph_0}$ as a subgraph if and only if $G$ has an end which is dominated by infinitely many vertices.

Definition 2.5 (Inflated graph). Given a graph $G$, we say that a pair $(H, \varphi_H)$ is an inflated copy of $G$, or an IG for short, if $H$ is a graph and $\varphi_H : V(H) \to V(G)$ is such that:

- For every $v \in V(G)$ the branch-set $\varphi_H^{-1}(v)$ induces a non-empty, connected subgraph of $H$;
- There is an edge in $H$ between $\varphi_H^{-1}(v)$ and $\varphi_H^{-1}(w)$ if and only if $(v, w) \in E(G)$ and this edge, if it exists, is unique.

When there is no danger of confusion we will simply say that $H$ is an IG instead of saying that $(H, \varphi_H)$ is an IG, and denote by $H(v)$ the branch-set of $v$. By definition, a graph $G$ is a minor of another graph $\Gamma$ if and only if there is some subgraph $H \subseteq \Gamma$ such that $H$ is an IG.

We will say an IG $(H, \varphi_H)$ is tidy if $H$ is subgraph-minimal such that the pair $(H, \varphi_H)$ is an IG, that is, $(H', \varphi_H | V(H'))$ is not an IG whenever $H' \subset H$. For a given IG $(H, \varphi)$ by Zorn’s lemma there is always a subgraph $H' \subseteq H$ such that $(H', \varphi | V(H'))$ is a tidy IG, however this choice may not be unique.

We note that in this case the subgraph of $H$ induced on $H(v)$ is a tree for every $v \in V(G)$, and every leaf of this tree is incident with some edge $(u, v) \in E(H)$ between two branch sets. Furthermore, if $d_G(v)$ is finite, than so is $H(v)$. In this paper we will always assume without loss of generality that each IG is tidy.

If $G \subseteq G'$ and $H$ is an IG we say that an IG $H' \supseteq H$ extends $H$ if $H(v) \subseteq H'(v)$ for all $v \in V(G) \cap V(G')$ and we say that $H'$ is an extension of $H$. Note that, since $H \subseteq H'$, for every $(v, w) \in E(G)$ the unique edge between $H'(v)$ and $H'(w)$ is also the unique edge between $H(v)$ and $H(w)$.

Definition 2.6 (Pullback). Let $G$ be a graph, $M \subseteq G$ a subgraph without isolated vertices, and let $H$ be a tidy IG. The pullback of $M$ to $H$ is the IM $(H(M), \varphi_H | V(H(M)))$ where $H(M) \subseteq H$ is the unique subgraph such that $(H(M), \varphi_H | V(H(M)))$ is a tidy IM.

Note that, due to the tidiness requirement, $H(M)$ might be a proper subgraph of $H[\varphi^{-1}_H(V(M))]$. The requirement that $M$ does not contain isolated vertices is necessary to make this subgraph unique, since if $M$ contains an isolated vertex $v$, then there isn’t a
Definition 3.1 (Ray graph). Given a finite family of disjoint rays \( \mathcal{R} = (R_i : i \in I) \) in a graph \( \Gamma \) the ray graph \( RG_\Gamma(\mathcal{R}) = RG_\Gamma(\mathcal{R}) = \{R_i : i \in I\} \) is the graph with vertex set \( I \) and with an edge between \( i \) and \( j \) if there is an infinite collection of vertex disjoint paths from \( R_i \) to \( R_j \) in \( \Gamma \) which meet no other \( R_k \). When the host graph \( \Gamma \) is clear from the context we will simply write \( RG(\mathcal{R}) \) for \( RG_\Gamma(\mathcal{R}) \).

The following lemmas are simple exercises. For a family \( \mathcal{R} \) of disjoint rays in \( G \) tending to the same end and \( H \subseteq \Gamma \) being an \( IG \) the aim is to establish the following: if \( \mathcal{S} \) is a family of disjoint rays in \( \Gamma \) which contains the pullback \( H(R) \) of each \( R \in \mathcal{R} \), then the subgraph of the ray graph \( RG(\mathcal{S}) \) induced on the vertices given by \( \{H(R) : R \in \mathcal{R}\} \) is connected.

Lemma 3.2. Let \( G \) be a graph and let \( \mathcal{R} = (R_i : i \in I) \) be a finite family of disjoint rays in \( G \). Then \( RG_G(\mathcal{R}) \) is connected if and only if all rays in \( \mathcal{R} \) tend to a common end \( \omega \in \Omega(G) \).

Lemma 3.3. Let \( G \) be a graph, \( \mathcal{R} = (R_i : i \in I) \) be a finite family of disjoint rays in \( G \) and let \( H \) be an IG. If \( \mathcal{R}' = (H(R_i) : i \in I) \) are the pullbacks of the rays in \( \mathcal{R} \) in \( H \), then \( RG_H(\mathcal{R}) = RG_H(\mathcal{R}') \).

Lemma 3.4. Let \( G \) be a graph, \( H \subseteq G \), \( \mathcal{R} = (R_i : i \in I) \) be a finite disjoint family of rays in \( H \) and let \( \mathcal{S} = (S_j : j \in J) \) be a finite disjoint family of rays in \( G - V(H) \), where \( I \) and \( J \) are disjoint. Then \( RG_H(\mathcal{R}) \) is a subgraph of \( RG_G(\mathcal{R} \cup \mathcal{S})[I] \). In particular, if all rays in \( \mathcal{R} \) tend to a common end in \( H \), then \( RG_G(\mathcal{R} \cup \mathcal{S})[I] \) is connected.

Recall that an end \( \omega \) of a graph \( G \) is called linear if for every finite set \( \mathcal{R} \) of at least three disjoint \( \omega \)-rays in \( G \) we can order the elements of \( \mathcal{R} \) as \( \mathcal{R} = \{R_1, R_2, \ldots, R_n\} \) such that for each \( 1 \leq k < i < \ell \leq n \), the rays \( R_k \) and \( R_\ell \) belong to different ends of \( G - V(R_i) \).
Lemma 3.5. An end $\omega$ of a graph $G$ is linear if and only if the ray graph of every finite family of disjoint $\omega$-rays is a path.

Proof. For the forward direction suppose $\omega$ is linear and $\{R_1, R_2, \ldots, R_n\}$ converge to $\omega$, with the order given by the definition of linear. It follows that there is no $1 \leq k < i < \ell \leq n$ such that $(k, \ell)$ is an edge in $RG(R_j: j \in [n])$. However, by Lemma 3.2 $RG(R_j: j \in [n])$ is connected, and hence it must be the path $12 \ldots n$.

Conversely, suppose that the ray graph of every finite family of $\omega$-rays is a path. Then, every such family $\mathcal{R}$ can be ordered as $\{R_1, R_2, \ldots, R_n\}$ such that $RG(\mathcal{R})$ is the path $12 \ldots n$. It follows that, for each $i$, $(k, \ell) \notin E(RG(\mathcal{R}))$ whenever $1 \leq k < i < \ell \leq n - 1$, and so by definition of $RG(\mathcal{R})$ there is no infinite collection of vertex disjoint paths from $R_k$ to $R_\ell$ in $G - V(R_i)$. Therefore $R_k$ and $R_\ell$ belong to different ends of $G - V(R_i)$. □

Definition 3.6 (Tail of a ray after a set). Given a ray $R$ in a graph $G$ and a finite set $X \subseteq V(G)$ the tail of $R$ after $X$, denoted by $T(R, X)$, is the unique infinite component of $R$ in $G - X$.

Definition 3.7 (Linkage of families of rays). Let $\mathcal{R} = (R_i: i \in I)$ and $\mathcal{S} = (S_j: j \in J)$ be families of disjoint rays of $\Gamma$, where the initial vertex of each $R_i$ is denoted $x_i$. A family $\mathcal{P} = (P_i: i \in I)$ of paths in $\Gamma$ is a linkage from $\mathcal{R}$ to $\mathcal{S}$ if there is an injective function $\sigma: I \to J$ such that

- Each $P_i$ goes from a vertex $x'_i \in R_i$ to a vertex $y_{\sigma(i)} \in S_{\sigma(i)}$;
- The family $\mathcal{T} = (x_i R_i x'_i P_i y_{\sigma(i)} S_{\sigma(i)}: i \in I)$ is a collection of disjoint rays.

We say that $\mathcal{T}$ is obtained by transitioning from $\mathcal{R}$ to $\mathcal{S}$ along the linkage. We say the linkage $\mathcal{P}$ induces the mapping $\sigma$. Given a vertex set $X \subseteq V(G)$ we say that the linkage is after $X$ if $X \cap V(R_i) \subseteq V(x_i R_i x'_i)$ for all $i \in I$ and no other vertex in $X$ is used by $\mathcal{T}$. We say that a function $\sigma: I \to J$ is a transition function from $\mathcal{R}$ to $\mathcal{S}$ if for any finite vertex set $X \subseteq V(G)$ there is a linkage from $\mathcal{R}$ to $\mathcal{S}$ after $X$ that induces $\sigma$.

We will need the following lemma from [5], which asserts the existence of linkages.

Lemma 3.8 (Weak linking lemma). Let $\Gamma$ be a graph, $\omega \in \Omega(\Gamma)$ and let $n \in \mathbb{N}$. Then for any two families $\mathcal{R} = (R_i: i \in [n])$ and $\mathcal{S} = (S_j: j \in [n])$ of vertex disjoint $\omega$-rays and any finite vertex set $X \subseteq V(G)$, there is a linkage from $\mathcal{R}$ to $\mathcal{S}$ after $X$.

§4. A PEBBLE-PUSHING GAME

Suppose we have a family of disjoint rays $\mathcal{R} = (R_i: i \in I)$ in a graph $G$ and a subset $J \subseteq I$. Often we will be interested in which functions we can obtain as transition functions
between \((R_i : i \in J)\) and \((R_i : i \in I)\). We can think of this as trying to ‘re-route’ the rays \((R_i : i \in J)\) to a different set of \(|J|\) rays in \((R_i : i \in I)\).

To this end, it will be useful to understand the following pebble-pushing game on a graph.

**Definition 4.1** (Pebble-pushing game). Let \(G = (V, E)\) be a finite graph. For any fixed positive integer \(k\) we call a tuple \((x_1, x_2, \ldots, x_k) \in V^k\) a game state if \(x_i \neq x_j\) for all \(i, j \in [k]\) with \(i \neq j\).

The pebble-pushing game (on \(G\)) is a game played by a single player. Given a game state \(Y = (y_1, y_2, \ldots, y_k)\), we imagine \(k\) labelled pebbles placed on the vertices \((y_1, y_2, \ldots, y_k)\). We move between game states by moving a pebble from a vertex to an adjacent vertex which does not contain a pebble, or formally, a \(Y\)-move is a game state \(Z = (z_1, z_2, \ldots, z_k)\) such that there is an \(\ell \in [k]\) such that \(y_\ell z_\ell \in E\) and \(y_i = z_i\) for all \(i \in [k] \setminus \{\ell\}\).

Let \(X = (x_1, x_2, \ldots, x_k)\) be a game state. The \(X\)-pebble-pushing game (on \(G\)) is a pebble-pushing game where we start with \(k\) labelled pebbles placed on the vertices \((x_1, x_2, \ldots, x_k)\).

We say a game state \(Y\) is achievable in the \(X\)-pebble-pushing game if there is a sequence \((X_i : i \in [n])\) of game states for some \(n \in \mathbb{N}\) such that \(X_1 = X\), \(X_n = Y\) and \(X_{i+1}\) is an \(X_i\)-move for all \(i \in [n-1]\), that is, if it is a sequence of moves that pushes the pebbles from \(X\) to \(Y\).

A graph \(G\) is \(k\)-pebble-win if \(Y\) is an achievable game state in the \(X\)-pebble-pushing game on \(G\) for every two game states \(X\) and \(Y\).

The following lemma shows that achievable game states on the ray graph \(RG(\mathcal{R})\) yield transition functions from a subset of \(\mathcal{R}\) to itself. Therefore, it will be useful to understand which game states are achievable, and in particular the structure of graphs on which there are unachievable game states.

**Lemma 4.2.** Let \(\Gamma\) be a graph, \(\omega \in \Omega(\Gamma)\), \(m \geq k\) be positive integers and let \((S_j : j \in [m])\) be a family of disjoint rays in \(\omega\). For every achievable game state \(Z = (z_1, z_2, \ldots, z_k)\) in the \((1, 2, \ldots, k)\)-pebble-pushing game on \(RG(S_j : j \in [m])\), the map \(\sigma\) defined via \(\sigma(i) := z_i\) for every \(i \in [k]\) is a transition function from \((S_i : i \in [k])\) to \((S_j : j \in [m])\).

**Proof.** We first note that if \(\sigma\) is a transition function from \((S_i : i \in [k])\) to \((S_j : j \in [m])\) and \(\tau\) is a transition function from \((S_i : i \in \sigma([k]))\) to \((S_j : j \in [m])\), then clearly \(\tau \circ \sigma\) is a transition function from \((S_i : i \in [k])\) to \((S_j : j \in [m])\).

Hence, it will be sufficient to show the statement holds when \(\sigma\) is obtained from \((1, 2, \ldots, k)\) by a single move, that is, there is some \(t \in [k]\) and a vertex \(\sigma(t) \notin [k]\) such that \(\sigma(t)\) is adjacent to \(t\) in \(RG(S_j : j \in [m])\) and \(\sigma(i) = i\) for \(i \in [k] \setminus \{t\}\).
So, let \( X \subseteq V(G) \) be a finite set. We will show that there is a linkage from \( (S_i: i \in [k]) \) to \( (S_j: j \in [m]) \) after \( X \) that induces \( \sigma \). By assumption there is an edge \( (t, \sigma(t)) \in E(RG(S_j: j \in [m])) \). Hence, there is a path \( P \) between \( T(S_t, X) \) and \( T(S_{\sigma(t)}, X) \) which avoids \( X \) and all other \( S_j \).

Then the family \( \mathcal{P} = (P_1, P_2, \ldots, P_k) \) where \( P_t = P \) and \( P_i = \emptyset \) for each \( i \neq t \) is a linkage from \( (S_i: i \in [k]) \) to \( (S_j: j \in [m]) \) after \( X \) that induces \( \sigma \). □

We note that this pebble-pushing game is sometimes known in the literature as “permutation pebble motion” [11] or “token reconfiguration” [6]. Previous results have mostly focused on computational questions about the game, rather than the structural questions we are interested in, but we note that in [11] the authors give an algorithm that decides whether or not a graph is \( k \)-pebble-win, from which it should be possible to deduce the main result in this section, Lemma 4.9. However, since a direct derivation was shorter and self contained, we will not use their results. We present the following simple lemmas without proof.

**Lemma 4.3.** Let \( G \) be a finite graph and \( X \) a game state.

- If \( Y \) is an achievable game state in the \( X \)-pebble-pushing game on \( G \), then \( X \) is an achievable game state in the \( Y \)-pebble-pushing game on \( G \).
- If \( Y \) is an achievable game state in the \( X \)-pebble-pushing game on \( G \) and \( Z \) is an achievable game state in the \( Y \)-pebble-pushing game on \( G \), then \( Z \) is an achievable game state in the \( X \)-pebble-pushing game on \( G \).

**Definition 4.4.** Let \( G \) be a finite graph and let \( X = (x_1, x_2, \ldots, x_k) \) be a game state. Given a permutation \( \sigma \) of \([k]\) let us write \( X^\sigma = (x_{\sigma(1)}, x_{\sigma(2)}, \ldots, x_{\sigma(k)}) \). We define the **pebble-permutation group** of \((G, X)\) to be the set of permutations \( \sigma \) of \([k]\) such that \( X^\sigma \) is an achievable game state in the \( X \)-pebble-pushing game on \( G \).

Note that by Lemma 4.3, the pebble-permutation group of \((G, X)\) is a subgroup of the symmetric group \( S_k \).

**Lemma 4.5.** Let \( G \) be a graph and let \( X \) be a game state. If \( Y \) is an achievable game state in the \( X \)-pebble-pushing game and \( \sigma \) is in the pebble-permutation group of \( Y \), then \( \sigma \) is in the pebble-permutation group of \( X \).

**Lemma 4.6.** Let \( G \) be a finite connected graph and let \( X \) be a game state. Then \( G \) is \( k \)-pebble-win if and only if the pebble-permutation group of \((G, X)\) is \( S_k \).

**Proof.** Clearly, if the pebble-permutation group is not \( S_k \) then \( G \) is not \( k \)-pebble-win. Conversely, since \( G \) is connected, for any game states \( X \) and \( Y \) there is some \( \tau \) such that \( Y^\tau \)
is an achievable game state in the $X$-pebble-pushing game, since we can move the pebbles to any set of $k$ vertices, up to some permutation of the labels. We know by assumption that $X^{τ−1}$ is an achievable game state in the $X$-pebble-pushing game. Therefore, by Lemma 4.3 $Y$ is an achievable game state in the $X$-pebble-pushing game. □

**Lemma 4.7.** Let $G$ be a finite connected graph and let $X = (x_1, x_2, \ldots, x_k)$ be a game state. If $G$ is not $k$-pebble-win, then there is a two colouring $c: X → \{r, b\}$ such that both colour classes are non trivial and for all $i, j ∈ [k]$ with $c(x_i) = r$ and $c(x_j) = b$ the transposition $(ij)$ is not in the pebble-permutation group.

**Proof.** Let us draw a graph $H$ on $\{x_1, x_2, \ldots, x_k\}$ by letting $(x_i, x_j)$ be an edge if and only if $(ij)$ is in the pebble-permutation group of $(G, X)$. It is a simple exercise to show that the pebble-permutation group of $(G, X)$ is $S_k$ if and only if $H$ has a single component.

Since $G$ is not $k$-pebble-win, we therefore know by Lemma 4.6 that there are at least two components in $H$. Let us pick one component $C_1$ and set $c(x) = r$ for all $x ∈ V(C_1)$ and $c(x) = b$ for all $x ∈ X \setminus V(C_1)$. □

**Definition 4.8.** Given a graph $G$, a path $x_1x_2 \ldots x_m$ in $G$ is a bare path if $d_G(x_i) = 2$ for all $2 ≤ i ≤ m − 1$.

**Lemma 4.9.** Let $G$ be a finite connected graph with vertex set $V$ which is not $k$-pebble-win and with $|V| ≥ k + 2$. Then there is a bare path $P = p_1p_2 \ldots p_n$ in $G$ such that $|V \setminus V(P)| ≤ k$. Furthermore, either every edge in $P$ is a bridge in $G$, or $G$ is a cycle.

**Proof.** Let $X = (x_1, x_2, \ldots, x_k)$ be a game state. Since $G$ is not $k$-pebble-win, by Lemma 4.7 there is a two colouring $c: \{x_i: i ∈ [k]\} → \{r, b\}$ such that both colour classes are non trivial and for all $i, j ∈ [k]$ with $c(x_i) = r$ and $c(x_j) = b$ the transposition $(ij)$ is not in the pebble permutation group. Let us consider this as a three colouring $c: V → \{r, b, 0\}$ where $c(v) = 0$ if $v ∉ \{x_1, x_2, \ldots, x_k\}$.

For every achievable game state $Z = (z_1, z_2, \ldots, z_k)$ in the $X$-pebble-pushing game we define a three colouring $c_Z$ given by $c_Z(z_i) = c(x_i)$ for all $i ∈ [k]$ and by $c_Z(v) = 0$ for all $v ∉ \{z_1, z_2, \ldots, z_k\}$. We note that, for any achievable game state $Z$ there is no $z_i ∈ c_Z^1(r)$ and $z_j ∈ c_Z^1(b)$ such that $(ij)$ is in the pebble permutation group of $(G, Z)$. Indeed, if it were, then by Lemma 4.3 $X^{(ij)}$ is an achievable game state in the $X$-pebble-pushing game, contradicting the fact that $c(x_i) = r$ and $c(x_j) = b$.

Since $G$ is connected, for every achievable game state $Z$ there is a path $P = p_1p_2 \ldots p_m$ in $G$ with $c_Z(p_1) = r$, $c_Z(p_m) = b$ and $c_Z(p_i) = 0$ otherwise. Let us consider an achievable game state $Z$ for which $G$ contains such a path $P$ of maximal length.
We first claim that there is no \( v \notin P \) with \( c_Z(v) = 0 \). Indeed, suppose there is such a vertex \( v \). Since \( G \) is connected there is some \( v-P \) path \( Q \) in \( G \) and so, by pushing pebbles towards \( v \) on \( Q \), we can achieve a game state \( Z' \) such that \( c_{Z'} = c_Z \) on \( P \) and there is a vertex \( v' \) adjacent to \( P \) such that \( c_{Z'}(v') = 0 \). Clearly \( v' \) cannot be adjacent to \( p_1 \) or \( p_m \), since then we can push the pebble on \( p_1 \) or \( p_m \) onto \( v' \) and achieve a game state \( Z'' \) for which \( G \) contains a longer path than \( P \) with the required colouring. However, if \( v' \) is adjacent to \( p_\ell \) with \( 2 \leq \ell \leq m - 1 \), then we can push the pebble on \( p_1 \) onto \( p_\ell \) and then onto \( v' \), then push the pebble from \( p_m \) onto \( p_1 \) and finally push the pebble on \( p_\ell \) and then onto \( p_m \).

However, if \( Z' = (z'_1, z'_2, \ldots, z'_k) \) with \( p_1 = z'_1 \) and \( p_m = z'_j \), then above shows that \((ij)\) is in the pebble-permutation group of \((G, Z')\). However, \( c_{Z'}(z_i') = c_Z(p_1) = r \) and \( c_{Z'}(z_j') = c_Z(p_m) = b \), contradicting our assumptions on \( c_Z \).

Next, we claim that each \( p_i \) with \( 3 \leq i \leq m - 2 \) has degree 2. Indeed, suppose first that \( p_i \) with \( 3 \leq i \leq m - 2 \) is adjacent to some other \( p_j \) with \( 1 \leq j \leq m \) such that \( p_i \) and \( p_j \) are not adjacent in \( P \). Then it is easy to find a sequence of moves which exchanges the pebbles on \( p_1 \) and \( p_m \), contradicting our assumptions on \( c_Z \).

Suppose then that \( p_i \) is adjacent to a vertex \( v \) not in \( P \). Then, \( c_Z(v) \neq 0 \), say without loss of generality \( c_Z(v) = r \). However then, we can push the pebble on \( p_m \) onto \( p_{i-1} \), push the pebble on \( v \) onto \( p_i \) and then onto \( p_m \) and finally push the pebble on \( p_{i-1} \) onto \( p_i \) and then onto \( v \). As before, this contradicts our assumptions on \( c_Z \).

Hence \( P' = p_2p_3\ldots p_{m-1} \) is a bare path in \( G \), and since every vertex in \( V - V(P') \) is coloured using \( r \) or using \( b \), there are at most \( k \) such vertices.

Finally, suppose that there is some edge in \( P' \) which is not a bridge of \( G \), and so no edge of \( P' \) is a bridge of \( G \). We wish to show that \( G \) is a cycle. We first make the following claim:

**Claim 4.10.** There is no achievable game state \( W = (w_1, w_2, \ldots, w_k) \) such that there is a cycle \( C = c_1c_2\ldots c_rc_1 \) and a vertex \( v \notin C \) such that:

- There exist distinct positive integers \( i, j, s \) and \( t \) such that \( c_W(c_i) = r, c_W(c_j) = b \) and \( c_W(c_s) = c_W(c_t) = 0 \);
- \( v \) adjacent to some \( c_v \in C \).

**Proof of Claim 4.10.** Suppose for a contradiction there exists such an achievable game state \( W \). Since \( C \) is a cycle we may assume without loss of generality that \( c_1 = c_1, c_s = c_2 = c_v, c_t = c_3 \) and \( c_j = c_4 \). If \( c_W(v) = b \), then we can push the pebble at \( v \) to \( c_2 \) and then to \( c_3 \), push the pebble at \( c_1 \) to \( c_2 \) and then to \( v \), and then push the pebble at \( c_3 \) to \( c_1 \). This contradicts our assumptions on \( c_W \). The case where \( c_W(v) = r \) is similar. Finally
if $c_W(v) = 0$, then we can push the pebble at $c_1$ to $c_2$ and then to $v$, then push the pebble at $c_4$ to $c_1$, then push the pebble at $v$ to $c_2$ and then to $c_4$. Again this contradicts our assumptions on $c_W$. □

Since no edge of $P'$ is a bridge, it follows that $G$ contains a cycle $C$ containing $P'$. If $G$ is not a cycle, then there is a vertex $v \in V \setminus C$ which is adjacent to $C$. However by pushing the pebble on $p_1$ onto $p_2$ and the pebble on $p_m$ onto $p_{m-1}$, which is possible since $|V| \geq k + 2$, we achieve a game state $Z'$ such that $C$ and $v$ satisfy the assumptions of the above claim, a contradiction. □

§5. Pebbly ends

**Definition 5.1** (Pebbly). Let $\Gamma$ be a graph and $\omega$ an end of $\Gamma$. We say $\omega$ is *pebbly* if for every $k \in \mathbb{N}$ there is an $n \geq k$ and a family $\mathcal{R} = (R_i: i \in [n])$ of disjoint rays in $\omega$ such that $RG(\mathcal{R})$ is $k$-pebble-win. If for some $k$ there is no such family $\mathcal{R}$, we say $\omega$ is *not $k$-pebble-win*.

The following is an immediate corollary of Lemma 4.9.

**Corollary 5.2.** Let $\omega$ be an end of a graph $\Gamma$ which is not $k$-pebble-win and let $\mathcal{R} = (R_i: i \in [m])$ be a family of $m \geq k + 2$ disjoint rays in $\omega$. Then there is a bare path $P = p_1p_2 \ldots p_n$ in $RG(R_i: i \in [m])$ such that $|[m] \setminus V(P)| \leq k$. Furthermore, each edge in $P$ is a bridge in $RG(R_i: i \in [m])$, or $RG(R_i: i \in [m])$ is a cycle.

Hence, if an end in $\Gamma$ is not pebbly, then we have some constraint on the behaviour of rays towards this end. In a later paper [3] we will investigate more precisely what can be said about the structure of the graph towards this end. For now, the following lemma allows us to easily find any countable graph as a minor of a graph with a pebbly end.

**Lemma 5.3.** Let $\Gamma$ be a graph and let $\omega \in \Omega(\Gamma)$ be a pebbly end. Then $K_{\aleph_0} \leq \Gamma$.

*Proof.* By assumption, there exists a sequence $\mathcal{R}_1, \mathcal{R}_2, \ldots$ of families of disjoint $\omega$-rays such that, for each $k \in \mathbb{N}$, $RG(\mathcal{R}_k)$ is $k$-pebble-win. Let us suppose that

$$\mathcal{R}_i = (R^i_1, R^i_2, \ldots, R^i_{m_i})$$

for each $i \in \mathbb{N}$.

Let us enumerate the vertices and edges of $K_{\aleph_0}$ by choosing some bijection $\sigma: \mathbb{N} \cup \mathbb{N}^{(2)} \to \mathbb{N}$ such that $\sigma(i, j) > \sigma(i), \sigma(j)$ for every $\{i, j\} \in \mathbb{N}^{(2)}$ and also $\sigma(1) < \sigma(2) < \cdots$. For each $k \in \mathbb{N}$ let $G_k$ be the graph on vertex set $V_k = \{i \in \mathbb{N} : \sigma(i) \leq k\}$ and edge set $E_k = \{(i, j) \in \mathbb{N}^{(2)} : \sigma(i, j) \leq k\}$.

We will inductively construct subgraphs $H_k$ of $\Gamma$ such that $H_k$ is an $IG_k$ extending $H_{k-1}$. Furthermore for each $k \in \mathbb{N}$ if $V(G_k) = [n]$ then there will be tails $T_1, T_2, \ldots, T_n$
of \( n \) distinct rays in \( \mathcal{R}_n \) such that for every \( i \in [n] \) the tail \( T_i \) meets \( H_k \) in a vertex of the branch set of \( i \), and is otherwise disjoint from \( H_k \). We will assume without loss of generality that \( T_i \) is a tail of \( R_i^n \).

Since \( \sigma(1) = 1 \) we can take \( H_1 \) to be the initial vertex of \( R_1^1 \). Suppose then that \( V(G_{n-1}) = [r] \) and we have already constructed \( H_{n-1} \) together with appropriate tails \( T_i \) of \( R_i^r \) for each \( i \in [r] \). Suppose firstly that \( \sigma^{-1}(n) = r + 1 \in \mathbb{N} \).

Let \( X = V(H_{n-1}) \). There is a linkage from \((T_i: i \in [r])\) to \((R_1^{r+1}, R_2^{r+1}, \ldots, R_r^{r+1})\) after \( X \) by Lemma 3.8, and, after relabelling, we may assume this linkage induces the identity on \([r]\). Let us suppose the linkage consists of paths \( P_i \) from \( x_i \in T_i \) to \( y_i \in R_i^{r+1} \).

Since \( X \cup \bigcup_i P_i \cup \bigcup_i T_i x_i \) is a finite set, there is some vertex \( y_{r+1} \) on \( R_i^{r+1} \) such that the tail \( y_{r+1} R_i^{r+1} \) is disjoint from \( X \cup \bigcup_i P_i \cup \bigcup_i T_i x_i \).

To form \( H_n \) we add the paths \( T_i x_i \cup P_i \) to the branch set of each \( i \leq r \) and set \( y_{r+1} \) as the branch set for \( r + 1 \). Then \( H_n \) is an \( IG_n \) extending \( H_{n-1} \) and the tails \( y_j R_j^{r+1} \) are as claimed.

Suppose then that \( \sigma^{-1}(n) = \{u, v\} \in \mathbb{N}^2 \) with \( u, v \leq r \). We have tails \( T_i \) of \( R_i^r \) for each \( i \in [r] \) which are disjoint from \( H_{n-1} \) apart from their initial vertices. Let us take tails \( T_j \) of \( R_j^r \) for each \( j > r \) which are also disjoint from \( H_{n-1} \). Since \( RG(\mathcal{R}_r) \) is \( r \)-pebble-win, it follows that \( RG(T_i: i \in [m_r]) \) is also \( r \)-pebble-win. Furthermore, since by Lemma 3.2 \( RG(T_i: i \in [m_r]) \) is connected, there is some neighbour \( w \in [m_r] \) of \( u \) in \( RG(T_i: i \in [m_r]) \).

Let us first assume that \( v \notin [r] \). Since \( RG(T_i: i \in [m_r]) \) is \( r \)-pebble-win, the game state \((1, 2, \ldots, v-1, w, v+1, \ldots, r)\) is an achievable game state in the \((1, 2, \ldots, r)\)-pebble-pushing game and hence by Lemma 4.2 the function \( \varphi_1 \) given by \( \varphi_1(i) = i \) for all \( i \in [r] \setminus \{v\} \) and \( \varphi_1(v) = w \) is a transition function from \((T_i: i \in [r])\) to \((T_i: i \in [m_r])\).

Let us take a linkage from \((T_i: i \in [r])\) to \((T_i: i \in [m_r])\) inducing \( \varphi_1 \) which is after \( V(H_{n-1}) \). Let us suppose the linkage consists of paths \( P_i \) from \( x_i \in T_i \) to \( y_i \in T_i \) for \( i \neq v \) and \( P_v \) from \( x_v \in T_v \) to \( y_v \in T_w \). Let

\[
X = V(H_{n-1}) \cup \bigcup_{i \in [r]} P_i \cup \bigcup_{i \in [r]} T_i x_i
\]

Since \( u \) is adjacent to \( w \) in \( RG(T_i: i \in [m_r]) \) there is a path \( \hat{P} \) between \( T(T_u, X) \) and \( T(T_w, X) \) which is disjoint from \( X \) and from all other \( T_i \), say \( \hat{P} \) is from \( \hat{x} \in T_u \) to \( \hat{y} \in T_w \).

Finally, since \( RG(T_i: i \in [m_r]) \) is \( r \)-pebble-win, the game state \((1, 2, \ldots, r)\) is an achievable game state in the \((1, 2, \ldots, v-1, w, v+1, \ldots, r)\)-pebble-pushing game and hence by Lemma 4.2 the function \( \varphi_2 \) given by \( \varphi_2(i) = i \) for all \( i \in [r] \setminus \{v\} \) and \( \varphi_2(w) = v \) is a transition function from \((T_i: i \in [r] \setminus \{v\} \cup \{w\})\) to \((T_i: i \in [m_r])\).
Let us take a further linkage from \((T_i: i \in [r] \setminus \{v\} \cup \{w\})\) to \((T_i: i \in [m_i])\) inducing \(\varphi_2\) which is after \(X \cup \hat{P} \cup T_u \hat{x} \cup y_v T_w \hat{y}\). Let us suppose the linkage consists of paths \(P'_i\) from \(x'_i \in T_i\) to \(y'_i \in T_i\) for \(i \in [r] \setminus \{v\}\) and \(P'_v\) from \(x'_v \in T_w\) to \(y'_v \in T_v\).

In the case that \(w \in [r]\), \(w < v\), say, the game state

\[
(1, 2, \ldots, w - 1, v, w + 1, \ldots, v - 1, w, v + 1, \ldots r)
\]

is an achievable game state in the \((1, 2, \ldots, r)\)-pebble pushing-game and we get, by a similar argument, all \(P_i, x_i, y_i, P'_i, x'_i, y'_i\) and \(\hat{P}\).

We build \(H_n\) from \(H_{n-1}\) by adjoining the following paths:

- for each \(i \neq v\) we add the path \(T_i x_i P_i y_i T_i x'_i P'_i y'_i\) to \(H_{n-1}\), adding the vertices to the branch set of \(i\);
- we add \(\hat{P}\) to \(H_{n-1}\), adding the vertices of \(V(\hat{P}) \setminus \{\hat{y}\}\) to the branch set of \(u\);
- we add the path \(T_v x_v P_v y_v T_w x'_v P'_v y'_v\) to \(H_{n-1}\), adding the vertices to the branch set of \(v\).

We note that, since \(\hat{y} \in y_v T_w x'_v\), the branch sets for \(u\) and \(v\) are now adjacent. Hence \(H_n\) is an \(IG_n\) extending \(H_{n-1}\). Finally the rays \(y'_i T_i\) for \(i \in [r]\) are appropriate tails of the used rays of \(\mathcal{R}_v\). 

As every countable graph is a subgraph of \(K_{\aleph_0}\), a graph with a pebbly end contains every countable graph as a minor. Thus, as \(\aleph_0 G\) is countable, if \(G\) is countable, we obtain the following corollary:

**Corollary 5.4.** Let \(\Gamma\) be a graph with a pebbly end \(\omega\) and let \(G\) be a countable graph. Then \(\aleph_0 G \preceq \Gamma\).

§6. \(G\)-tribes and concentration of \(G\)-tribes towards an end

To show that a given graph \(G\) is \(\preceq\)-ubiquitous, we shall assume that \(nG \preceq \Gamma\) holds for every \(n \in \mathbb{N}\) an show that this implies \(\aleph_0 G \preceq \Gamma\). To this end we use the following notation for such collections of \(nG\) in \(\Gamma\), most of which we established in [5].

**Definition 6.1** (\(G\)-tribes). Let \(G\) and \(\Gamma\) be graphs.

- A \(G\)-tribe in \(\Gamma\) (with respect to the minor relation) is a family \(\mathcal{F}\) of finite collections \(F\) of disjoint subgraphs \(H\) of \(\Gamma\) such that each member \(H\) of \(\mathcal{F}\) is an \(IG\).
- A \(G\)-tribe \(\mathcal{F}\) in \(\Gamma\) is called thick, if for each \(n \in \mathbb{N}\) there is a layer \(F \in \mathcal{F}\) with \(|F| \geq n\); otherwise, it is called thin.
- A \(G\)-tribe \(\mathcal{F}'\) in \(\Gamma\) is a \(G\)-subtribe of (\(G\)-tribe \(\mathcal{F}\) in \(\Gamma\), denoted by \(\mathcal{F}' \preceq \mathcal{F}\), if there is an injection \(\Psi: \mathcal{F}' \rightarrow \mathcal{F}\) such that for each \(F'' \in \mathcal{F}'\) there is an injection

\[\text{When } G \text{ is clear from the context we will often refer to a } G\text{-subtribe as simply a subtribe.}\]
\[ \varphi_{F'} : F' \to \Psi(F') \] such that \( V(H') \subseteq V(\varphi_{F'}(H')) \) for each \( H' \in F' \). The \( G \)-subtribe \( F' \) is called flat, denoted by \( F' \subseteq F \), if there is such an injection \( \Psi \) satisfying \( F' \subseteq \Psi(F') \).

- A thick \( G \)-tribe \( F \) in \( \Gamma \) is concentrated at an end \( \epsilon \) of \( \Gamma \), if for every finite vertex set \( X \) of \( \Gamma \), the \( G \)-tribe \( F_X = \{ F_X : F \in \mathcal{F} \} \) consisting of the layers \( F_X = \{ H \in F : H \not\subseteq C(X, \epsilon) \} \subseteq F \) is a thin subtribe of \( \mathcal{F} \). It is strongly concentrated at \( \epsilon \) if additionally, for every finite vertex set \( X \) of \( \Gamma \), every member \( H \) of \( \mathcal{F} \) intersects \( C(X, \epsilon) \).

We note that, every thick \( G \)-tribe \( \mathcal{F} \) contains a thick subtribe \( F' \) such that every \( H \in \bigcup \mathcal{F} \) is a tidy \( IG \). We will use the following lemmas from [5].

**Lemma 6.2** (Removing a thin subtribe, [5, Lemma 5.2]). Let \( \mathcal{F} \) be a thick \( G \)-tribe in \( \Gamma \) and let \( F' \) be a thin subtribe of \( \mathcal{F} \), witnessed by \( \Psi : F' \to \mathcal{F} \) and \( (\varphi_{F'} : F' \in F') \). For \( F \in \mathcal{F} \), if \( F \in \Psi(F') \), let \( \Psi^{-1}(F) = \{ F' : F \} \) and set \( \hat{F} = \varphi_{F'}(F') \). If \( F \not\in \Psi(F') \), set \( \hat{F} = \emptyset \). Then

\[ F'' := \{ F \setminus \hat{F} : F \in \mathcal{F} \} \]

is a thick flat \( G \)-subtribe of \( \mathcal{F} \).

**Lemma 6.3** (Pigeon hole principle for thick \( G \)-tribes, [5, Lemma 5.3]). Suppose for some \( k \in \mathbb{N} \), we have a \( k \)-colouring \( c : \bigcup \mathcal{F} \to [k] \) of the members of some thick \( G \)-tribe \( \mathcal{F} \) in \( \Gamma \). Then there is a monochromatic, thick, flat \( G \)-subtribe \( F' \) of \( \mathcal{F} \).

Note that, in the following lemma, it is necessary that \( G \) is connected, so that every member of the \( G \)-tribe is a connected graph.

**Lemma 6.4** ([5, Lemma 5.4]). Let \( G \) be a connected graph and \( \Gamma \) a graph containing a thick \( G \)-tribe \( \mathcal{F} \). Then either \( \aleph_0 G \not\approx \Gamma \), or there is a thick flat subtribe \( F' \) of \( \mathcal{F} \) and an end \( \epsilon \) of \( \Gamma \) such that \( \mathcal{F}' \) is concentrated at \( \epsilon \).

**Lemma 6.5** ([5, Lemma 5.5]). Let \( G \) be a connected graph and \( \Gamma \) a graph containing a thick \( G \)-tribe \( \mathcal{F} \) concentrated at an end \( \epsilon \) of \( \Gamma \). Then the following assertions hold:

1. For every finite set \( X \), the component \( C(X, \epsilon) \) contains a thick flat \( G \)-subtribe of \( \mathcal{F} \).
2. Every thick subtribe \( \mathcal{F}' \) of \( \mathcal{F} \) is concentrated at \( \epsilon \), too.

**Lemma 6.6.** Let \( G \) be a connected graph and \( \Gamma \) a graph containing a thick \( G \)-tribe \( \mathcal{F} \) concentrated at an end \( \epsilon \in \Omega(\Gamma) \). Then either \( \aleph_0 G \not\approx \Gamma \), or there is a thick flat subtribe of \( \mathcal{F} \) which is strongly concentrated at \( \epsilon \).
Proof. Suppose that no thick flat subtribe of $\mathcal{F}$ is strongly concentrated at $\epsilon$. We construct an $\aleph_0 G \preceq \Gamma$ by recursively choosing disjoint IGs $H_1, H_2, \ldots$ in $\Gamma$ as follows: Having chosen $H_1, H_2, \ldots, H_n$ such that for some finite set $X_n$ we have

$$H_i \cap C(X_n, \epsilon) = \emptyset$$

for all $i \in [n]$, then by Lemma 6.5(1), there is still a thick flat subtribe $\mathcal{F}'_n$ of $\mathcal{F}$ contained in $C(X_n, \epsilon)$. Since by assumption, $\mathcal{F}'_n$ is not strongly concentrated at $\epsilon$, we may pick $H_{n+1} \in \mathcal{F}'_n$ and a finite set $X_{n+1} \supseteq X_n$ with $H_{n+1} \cap C(X_{n+1}, \epsilon) = \emptyset$. Then the union of all the $H_i$ is an $\aleph_0 G \preceq \Gamma$. □

The following lemma will show that we can restrict ourself to thick $G$-tribes which are concentrated at thick ends.

**Lemma 6.7.** Let $G$ be a connected graph and $\Gamma$ a graph containing a thick $G$-tribe $\mathcal{F}$ concentrated at an end $\epsilon \in \Omega(\Gamma)$ which is thin. Then $\aleph_0 G \preceq \Gamma$.

Proof. Since $\epsilon$ is thin, we know by Proposition 2.4 that only finitely many vertices dominate $\epsilon$. Deleting these yields a subgraph of $\Gamma$ in which there is still a thick $G$-tribe concentrated at $\epsilon$. Hence we may assume without loss of generality that $\epsilon$ is not dominated by any vertex in $\Gamma$.

Let $k \in \mathbb{N}$ be the degree of $\epsilon$. By [8, Corollary 5.5] there is a sequence of vertex sets $(S_n: n \in \mathbb{N})$ such that:

- $|S_n| = k$,
- $C(S_{n+1}, \epsilon) \subseteq C(S_n, \epsilon)$, and
- $\bigcap_{n \in \mathbb{N}} C(S_n, \epsilon) = \emptyset$.

Suppose there is a thick subtribe $\mathcal{F}'$ of $\mathcal{F}$ which is strongly concentrated at $\epsilon$. For any $F \in \mathcal{F}'$ there is an $N_F \in \mathbb{N}$ such that $H \setminus C(S_{N_F}, \epsilon) \neq \emptyset$ for all $H \in F$ by the properties of the sequence. Furthermore, since $\mathcal{F}'$ is strongly concentrated, $H \cap C(S_{N_F}, \epsilon) \neq \emptyset$ as well for each $H \in F$.

Let $F \in \mathcal{F}'$ be such that $|F| > k$. Since $G$ is connected, so is $H$, and so from the above it follows that $H \cap S_{N_F} \neq \emptyset$ for each $H \in F$, contradicting the fact that $|S_{N_F}| = k < |F|$. Thus $\aleph_0 G \preceq \Gamma$ by Lemma 6.6. □

Note that, whilst concentration is hereditary for subtribes, strong concentration is not. However if we restrict to flat subtribes, then strong concentration is a hereditary property.

Let us show see how ends of the members of a strongly concentrated tribe relate to ends of the host graph $\Gamma$. Let $G$ be a connected graph and $H \subseteq \Gamma$ an IG. By Lemmas 3.2 and 3.4, if $\omega \in \Omega(G)$ and $R_1$ and $R_2 \in \omega$ then the pullbacks $H(R_1)$ and $H(R_2)$ belong
to the same end $\omega' \in \Omega(\Gamma)$. Hence, $H$ determines for every end $\omega \in G$ a pullback end $H(\omega) \in \Omega(\Gamma)$. The next lemma is where we need to use the assumption that $G$ is locally finite.

**Lemma 6.8.** Let $G$ be a locally finite connected graph and $\Gamma$ a graph containing a thick $G$-tribe $F$ strongly concentrated at an end $\epsilon \in \Omega(\Gamma)$ where every member is a tidy $IG$. Then either $\aleph_0 G \preceq \Gamma$, or there is a flat subtribe $F'$ of $F$ such that for every $H \in \bigcup_{F'}$ there is an end $\omega_H \in \Omega(G)$ such that $H(\omega_H) = \epsilon$.

**Proof.** Since $G$ is locally finite and every $H \in \bigcup_{F'}$ is tidy, the branch sets $H(v)$ are finite for each $v \in V(G)$. If $\epsilon$ is dominated by infinitely many vertices, then we know by Proposition 2.4 that $\Gamma$ contains a topological $K_{\aleph_0}$ minor, in which case $\aleph_0 G \preceq \Gamma$, since every locally finite connected graph is countable. If this is not the case, then there is some $k \in \mathbb{N}$ such that $\epsilon$ is dominated by $k$ vertices and so for every $F \in F$ at most $k$ of the $H \in F$ contain vertices which dominate $\epsilon$ in $\Gamma$. Therefore, there is a thick flat subtribe $F'$ of $F$ such that no $H \in \bigcup_{F'}$ contains a vertex dominating $\epsilon$ in $\Gamma$. Note that $F'$ is still strongly concentrated at $\epsilon$, and every branch set of every $H \in \bigcup_{F'}$ is finite.

Since $F'$ is strongly concentrated at $\epsilon$, for every finite vertex set $X$ of $\Gamma$ every $H \in \bigcup_{F'}$ intersects $C(X, \epsilon)$. By a standard argument, since $H$ as a connected infinite graph does not contain a vertex dominating $\epsilon$ in $\Gamma$, instead $H$ contains a ray $R_H \subseteq \epsilon$.

For a subgraph $K \subseteq H$ let us define $K^\dagger$ to be the subgraph of $G$ where $V(K^\dagger) = \varphi_H(K)$ and $(v, w) \in E(K^\dagger)$ if and only if $K$ contains the edge in $H$ between $H(v)$ and $H(w)$. Then, since each $H(v)$ is finite, $R_H^\dagger \subseteq G$ is an infinite subgraph of a locally finite connected graph, and hence includes a ray $S_H$ in $G$. Furthermore, by construction, $V(H(S_H)) \subseteq V(R_H)$ and so the pullback of $S_H$ tends to $\epsilon$ in $\Gamma$. Hence, if $S_H$ tends to $\omega_H \in \Omega(G)$ then $H(\omega_H) = \epsilon$. \hfill \Box

§7. Ubiquity of minors of the half grid

Here, and in the following, we denote by $\mathbb{H}$ the infinite, one-ended, cubic hexagonal half grid (see Figure 7.1). The following theorem of Halin is one of the cornerstones of infinite graph theory.

**Theorem 7.1** (Halin, see [7, Theorem 8.2.6]). Whenever a graph $\Gamma$ contains a thick end, then $\mathbb{H} \preceq \Gamma$. \hfill \Box

In [10], Halin used this result to show that every topological minor of $\mathbb{H}$ is ubiquitous with respect to the topological minor relation $\preceq$. In particular, trees of maximum degree 3 are ubiquitous with respect to $\preceq$. 
However, the following argument, which is a slight adaptation of Halin’s, shows that every connected minor of $\mathbb{H}$ is ubiquitous with respect to the minor relation. In particular, the dominated ray, the dominated double ray, and all countable trees are ubiquitous with respect to the minor relation.

The main difference to Halin’s original proof is that, since he was only considering locally finite graphs, he was able to assume that the host graph $\Gamma$ was also locally finite.

**Lemma 7.2** ([10, (4) in Section 3]). $\aleph_0 \mathbb{H}$ is a topological minor of $\mathbb{H}$.

**Theorem 1.4.** Any connected minor of the half grid $\mathbb{N} \Box \mathbb{Z}$ is $\preccurlyeq$-ubiquitous.

**Proof.** Suppose $G \preccurlyeq \mathbb{N} \Box \mathbb{Z}$ is a minor of the half grid, and $\Gamma$ is a graph such that $nG \preccurlyeq \Gamma$ for each $n \in \mathbb{N}$. By Lemma 6.4 we may assume there is an end $\epsilon$ of $\Gamma$ and a thick $G$-tribe $\mathcal{F}$ which is concentrated at $\epsilon$. By Lemma 6.7 we may assume that $\epsilon$ is thick. Hence $\mathbb{H} \preccurlyeq \Gamma$ by Theorem 7.1, and with Lemma 7.2 we obtain

$$
\aleph_0 G \preccurlyeq \aleph_0 (\mathbb{N} \Box \mathbb{Z}) \preccurlyeq \aleph_0 \mathbb{H} \preccurlyeq \mathbb{H} \preccurlyeq \Gamma.
$$

**Lemma 7.3.** $\mathbb{H}$ contains every countable tree as a minor.

**Proof.** It is easy to see that the infinite binary tree $T_2$ embeds into $\mathbb{H}$ as a topological minor. It is also easy to see that countably regular tree $T_\infty$ where every vertex has infinite degree embeds into $T_2$ as a minor. And obviously, every countable tree $T$ is a subgraph of $T_\infty$. Hence we have

$$
T \subseteq T_\infty \preccurlyeq T_2 \preccurlyeq \mathbb{H}
$$

from which the result follows.

**Corollary 7.4.** All countable trees are ubiquitous with respect to the minor relation.

**Proof.** This is an immediate consequence of Lemma 7.3 and Theorem 1.4.
§8. Proof of main results

Theorem 1.2. Every locally finite connected graph with nowhere-linear end structure is ≼-ubiquitous.

Proof. Let $\Gamma$ be a graph such that $nG \preceq \Gamma$ holds for every $n \in \mathbb{N}$. Thus $\Gamma$ contains a thick $G$-tribe $F$. By Lemmas 6.4 and 6.6 we may assume that $F$ is strongly concentrated at an end $\epsilon$ of $\Gamma$ and so by Lemma 6.8 we may assume that for every $H \in \bigcup F$ there is an end $\omega_H \in \Omega(G)$ such that $H(\omega_H) = \epsilon$.

Our aim now is to show that $\epsilon$ is pebbly, which will complete the proof by Corollary 5.4. So, let us assume for contradiction that there is some $k \in \mathbb{N}$ such that $\epsilon$ is not $k$-pebble-win. Since $F$ is thick there is some $F \in F$ which contains $k+2$ disjoint $IG$s, $H_1, H_2, \ldots, H_{k+2}$. Since by assumption $G$ has nowhere-linear end structure, by Lemma 3.5 for each $i \in [k+2]$ there is a family of disjoint rays $\{R_{i,1}, R_{i,2}, \ldots, R_{i,m_i}\}$ in $G$ tending to $\omega_{H_i}$ whose ray graph in $G$ is not a path. Let

$$S = (H_i(R_{i,j}^i) : i \in [k+2], j \in [m_i]).$$

By construction $S$ is a disjoint family of rays which tend to $\epsilon$ in $\Gamma$ and by Lemma 3.3 and Lemma 3.4 $RG_{\Gamma}(S)$ contains disjoint subgraphs $K_1, K_2, \ldots, K_{k+2}$ such that $K_i \cong RG_G(R_{i}^i : j \in [m_i])$. However, by Corollary 5.2, there is a set $X$ of vertices of size at most $k$ such that $RG_{\Gamma}(S) - X$ is a bare path $P$. However, then some $K_i \subseteq P$ is a path, a contradiction.

Figure 8.1. The ray graphs in the full grid are cycles.
Corollary 1.3. The full grid is $\preceq$-ubiquitous.

Proof. Let $G$ be the full grid. Since $G - R$ has at most one end for any ray $R \in G$, by Lemma 3.2 the ray graph $RG(R)$ is 2-connected for any finite family of three or more rays. Hence, by Theorem 1.2 $G$ is $\preceq$-ubiquitous. □

Remark 8.1. In fact, every ray graph in the full grid is a cycle (see Figure 8.1).

Theorem 1.5. For every locally finite connected graph $G$, both $G \Box \mathbb{Z}$ and $G \Box \mathbb{N}$ are $\preceq$-ubiquitous.

Proof. If $G$ is a path or a ray, then $G \Box \mathbb{Z}$ is a subgraph of the half grid $\mathbb{N} \Box \mathbb{Z}$ and thus $\preceq$-ubiquitous by Theorem 1.4. If $G$ is a double ray then $G \Box \mathbb{Z}$ is the full grid and thus $\preceq$-ubiquitous by Corollary 1.3. Otherwise let $G'$ be a finite connected subgraph of $G$ which is not a path. For any end $\omega$ of $G \Box \mathbb{Z}$ there is a ray $R$ of $\mathbb{Z}$ such that all rays of the form $\{v\} \Box R$ for $v \in V(G)$ go to $\omega$. But then $G'$ is a subgraph of $RG_{G \Box \mathbb{Z}}((\{v\} \Box R)_{v \in V(G')})$, so this ray-graph is not a path, hence by Lemma 3.5 $G \Box \mathbb{Z}$ has nowhere-linear end structure and is therefore $\preceq$-ubiquitous by Theorem 1.2. □

Finally let us prove Theorem 1.6. Recall that for $k \in \mathbb{N}$ let $DR_k$ denote the graph formed by taking a ray $R$ together with $k$ vertices $v_1, v_2, \ldots, v_k$ adjacent to each vertex of $R$.

Theorem 1.6. The $k$-fold dominated ray $DR_k$ is $\preceq$-ubiquitous for every $k \in \mathbb{N}$.

Proof. Note that if $k \leq 2$ then $DR_k$ is a minor of the half grid, and hence ubiquity follows from Theorem 1.4.

Suppose then that $k \geq 3$ and $\Gamma$ is a graph which contains a thick $DR_k$-tribe $\mathcal{F}$ all of whose members are tidy. By Lemma 6.6 we may assume that there is an end $\epsilon$ of $\Gamma$ such that $\mathcal{F}$ is concentrated at $\epsilon$. If there are infinitely many vertices dominating $\epsilon$, then $\aleph_0 DR_k \preceq K_{\aleph_0} \preceq \Gamma$ holds by Proposition 2.4. So we may assume that only finitely many vertices dominate $\epsilon$. By taking a thick subtribe if necessary, we may assume that no member of $\mathcal{F}$ contains such a vertex.

As before, if we can show that $\epsilon$ is pebbly, then we will be done by Corollary 5.4. So suppose for a contradiction that $\epsilon$ is not $r$-pebble-win for some $r \in \mathbb{N}$.

Let $R$ be the ray as stated in the definition of $DR_k$ and let $v_1, v_2, \ldots, v_k \in V(DR_k)$ be the vertices adjacent to each vertex of $R$. For each $i \in [k]$ let $S_i$ denote the star in $V(DR_k)$ consisting of $v_i$ and all incident edges. For each $H \in \bigcup \mathcal{F}$ and each $i \in [k]$ we have that $H(S_i)$ is a locally finite infinite tree since $H$ is tidy and any vertex of $H(S_i)$ whose degree is infinite would dominate $\epsilon$. So $H(S_i)$ includes a ray, call it $R_{H,i}$.
by Proposition 2.3. Let $R_H = H(R)$ be the pullback of the ray $R$ in $H$. Now we set $\mathcal{R}_H = (R_{H,1}, R_{H,2}, \ldots, R_{H,k}, R_H)$.

Since all leaves of $H(S_i)$ are in branch sets of vertices of $R$, it follows that in the graph $RG_H(\mathcal{R}_H)$ each $R_{H,i}$ is adjacent to $R_H$. Hence $RG_H(\mathcal{R}_H)$ contains a vertex of degree $k \geq 3$.

There is some layer $F \in \mathcal{F}$ of size $\ell \geq r + 1$, say $F = (H_i : i \in [\ell])$. For every $i \in [r+1]$ we set $\mathcal{R}_{H,i} = (R_{H,i,1}, R_{H,i,2}, \ldots, R_{H,i,k}, R_{H,i})$. Let us now consider the family of disjoint rays

$$\mathcal{R} = \bigcup_{i=1}^{r+1} \mathcal{R}_{H,i}.$$ 

By construction $\mathcal{R}$ is a family of disjoint rays which tend to $\epsilon$ in $\Gamma$ and by Lemma 3.3 and Lemma 3.4 $RG_\Gamma(\mathcal{R})$ contains $r + 1$ vertices whose degree is at least $k \geq 3$. However, by Corollary 5.2, there is a vertex set $X$ of size at most $r$ such that $RG_\Gamma(\mathcal{R}) - X$ is a bare path $P$. But then some vertex whose degree is at least 3 is contained in the bare path, a contradiction. \(\square\)
