Histone deacetylase inhibitors induce expression of chromosomally tagged variant-specific surface protein genes in *Giardia lamblia*

Daniel Roberto Orozco and Srinivas Garlapati*

**Abstract**

**Objective:** RNA interference and miRNA mediated mechanisms have been proposed to explain the expression of a specific variant of VSP at a time on the surface of *Giardia lamblia*. Recently, epigenetic mechanisms involving histone acetylations have been proposed to explain the process of *vsp* gene switching in *Giardia lamblia*. However, due to the limited availability of specific antibodies for all the *vsp* variants present in the genome, it was difficult to monitor *vsp* gene switching. In this study, we have used an endogenous tagging method to tag specific *vsp* genes *vsp1267* and *vsp9B10A* with a sequence encoding hemagglutinin (HA) epitope at the 3′ end of the coding sequences without altering the 5′ upstream elements. With this method, we have monitored the expression of the tagged *vsp* genes in cells treated with histone deacetylase inhibitors using RT-PCR.

**Results:** Our results show that *vsp1267-3XHA* can be induced by treatment with sodium 4-phenylbutyrate, M344 and splitomicin but not by apicidin and Trichostatin A, while *vsp9B10A-3XHA* expression can be induced by Trichostatin A and splitomicin but not by sodium 4-phenylbutyrate, M344 and apicidin. The induced expression of these variants was not due to growth inhibition. These results support the role of histone acetylations in *vsp* expression.

**Introduction**

*Giardia lamblia* antigenic variation involves the expression of a single variant-specific surface protein (VSP) on the trophozoite surface from a library of approximately 200 distinct *vsp* genes [1]. VSPs cover the entire surface of *Giardia* trophozoites, including the flagella and ventral disk [2]. The dense transmembrane regions of VSPs are speculated to provide a protective barrier to prevent the host immune system from accessing the trophozoite plasma membrane [3]. Although RNAi and miRNA mechanisms that target the coding sequences of *vsp* transcripts explain how one VSP is expressed at a time [4, 5], they do not explain how VSP switching occurs. Epigenetic mechanisms have been proposed to explain the VSP switching in *Giardia* [3, 6, 7]. Recently, it was demonstrated that histone deacetylase inhibitor (HDACi) Trichostatin A increases the rate of VSP switching after 5 days of treatment, while sodium butyrate and nicotinamide had minor effects on switching rates [6]. The increase in switching rate was attributed to the increase in the association of H3K9ac, H4K8ac, and H4K16ac with the 5′ upstream sequences of *vsp1267*, the specific *vsp* used in the study. Also, the genes that not are expressed...
(vsp910B and vspa6) showed a significant decrease in the acetylation of histones associated with the 5′ upstream sequences [6]. However, it was not possible to detect the new VSPs expressed after switching due to a limitation in the availability of monoclonal antibodies for all the 200 possible variants of VSPs [6].

In this study, we have monitored the expression of chromosomally-tagged vsp genes vsp1267 and vsp9B10A in separate cell lines that were treated with histone deacetylase inhibitors. Due to a high degree of sequence similarity of VSPs, monitoring the expression of a specific vsp gene is difficult as it requires monoclonal antibodies that recognize it. However, by tagging a specific vsp gene, it is easy to detect its expression by RT-PCR. In order to ensure our chromosomally integrated construct is reflective of an endogenous vsp, the 5′ end of the vsp gene was unaltered, which is where epigenetic mechanisms generally operate. Our results show that treatment with HDAC inhibitors resulted in the expression of the tagged vsp gene more often than compared to untreated controls.

Main text

Methods

VSP cloning

The truncated vsp1267 gene (GL50803_112208) lacking the coding sequences for the first 20 amino acids (Fig. 1a) was amplified using the primers 5′-CACgccccgcgTGG AATAGTTGTGAAGCTGG-3′ (forward) and 5′-CAC tccgggCGCCCTCCCCTGCAATG-3′ (reverse) that contain recognition sequences for restriction enzymes Not I and Xho I, respectively. Similarly, truncated vsp9B10A gene (GL50803_101074) lacking the coding sequences for the first 20 amino acids (Fig. 1a) was amplified using the primers 5′-CACgccccgcgAACCAGGCG CGCGCAAGAAGCTC-3′ (forward) and 5′-GTGctc gagCAGCCTTGCTCTTCAGATAAC-3′ (reverse) containing sites for enzymes Not I and Xho I, respectively. The amplified genes were cloned into pGEM-T easy vectors (Promega, Madison WI) and the recombinant plasmids were sequenced. The truncated vsp genes (vsp1267tr and vsp9B10Atr) from pGEM-T easy vectors were then cloned into pKS-BSR-3XHA vector [8] upstream of a 3X HA sequence to generate pKS-BSR-(vsp1267tr-3XHA) vector.

Transfection

Recombinant plasmids pKS-vsp1267-3XHA and pKS-vsp9B10A-3XHA were linearized using Eco721 restriction enzyme, which cuts once in the coding sequences of truncated vsp genes. The digested plasmids were then transfected into Giardia lamblia WB trophozoites and selected for blastidicin resistance as described previously [8]. To confirm the chromosomal integration and 3XHA tagging of a copy of vsp gene, a forward primer corresponding to the 5′end of the coding sequence of the vsp gene (vsp1267 primer 5′-ATGTGGTGATGCCTTTC TATC-3′; vsp9B10A primer 5′-GTCATATGACTGCC AAAAATTGCGGATTGATATTG-3′) and a reverse primer (5′-TCCAGTATACCTGATCTGC-3′) corresponding to the 3XHA tag sequence from the plasmid vector were used to amplify the endogenously tagged vsp genes.

Vsp gene expression

Total RNA was extracted from untreated and HDAC inhibitor treated cells using TRIzol reagent by following the manufacturer’s instructions (Invitrogen). RNA samples were treated with DNase I (New England Biolabs) for 30 min at 37 °C to remove DNA contamination. One µg of treated RNA was used for cDNA synthesis using OneTaq RT-PCR kit (New England Biolabs) by following the manufacturer’s instructions. To amplify full-length transcripts with 3XHA tag, a forward primer that encompasses the entire length of the coding sequence and a reverse primer that corresponds to 3X HA were used. Coding sequences of the full length GlelF4A (GL50803_10255) transcripts were used as an internal control.

Effect of HDACi on the growth of Giardia

Giardia cell lines were grown to mid-late log phase of growth and were sub-cultured to contain approximately 105 cells/mL and treated with HDAC inhibitors apicidin, trichostatin A (TSA), sodium 4-phenylbutyrate (NaPB), M344 and splitomicin (Sigma-Aldrich) at a final concentration of 2µM. Trophozoites were incubated at 37 °C and the growth of parasites were monitored by counting the cells using a hemocytometer after 24 and 48 h post-treatment.

Results

Endogenous tagging

The plasmid constructs pKS-BSR-vsp1267tr-3XHA and pKS-BSR-9B10Atr-3XHA were linearized with Eco721 and transfected into Giardia cells (Fig. 1a). To confirm the integration of the truncated and tagged version of the vsp gene, primers encompassing the entire coding sequence starting from the initiation codon to the stop codon located after the triple HA tag were used (Fig. 1b). Amplification of full length HA tagged vsp1267 of size 1.7 Kb (Fig. 1c lane 2) and full length HA tagged vsp9B10 of size 2.2 Kb (Fig. 1d, lane 2), indicated proper integration of the 3XHA tagged gene into the chromosome.

**HDACi induce transcription of endogenously tagged vsp genes**

To test the hypothesis that inhibition of histone deacetylase activity leads to the expression of vsp genes, trophozoites were incubated with 2 µM concentrations of HDAC inhibitors for 24 h. Total RNA was extracted from *Giardia* cell lines Glvsp1267-3HA and Glvsp9B10A-3XHA after 24 h post-treatment. Reverse transcription polymerase chain reaction (RT-PCR) was performed to detect for HA-tagged vsp gene expression using a full-length vsp primer and a 3XHA primer (Fig. 1b). Additionally, *Giardia lamblia* eukaryotic translation initiation factor 4A (*GleIF4A*) was used as an internal control. A full length amplicon of size 1.7 Kb was detected in Glvsp1267-3XHA cell lines that were treated with M344, NaPB and splitomicin but not in the untreated control (Fig. 2a, lanes 5, 7, 11). For M344 and NaPB treatments, full length amplicon of vsp1267-3XHA was detected in 2 out of 3 separate experiments performed on different days. In splitomicin treated cell lines, 8 out of 13 independent experiments detected full length amplicon. In the experiments where the full length amplicons were not detected when treated with M344, NaPB or splitomicin, a smear of amplicons ranging from 0.5 to 1 Kb

**Fig. 2** Induction of vsp gene expression in *Giardia* trophozoites treated with Histone deacetylase inhibitors. **a** RT-PCR analysis of full length vsp1267-3XHA transcripts in untreated Glvsp1267-3XHA cell lines (lane 1), in cell lines treated with Apicidin (lane 3), M344 (lane 5), NaPB (lane 7), splitomicin (lane 9) and TSA (lane 11). RT-PCR of full length transcripts of GleIF4A (lanes, 2, 4, 6, 8, 10, and 12) was used as an internal control. **b** RT-PCR analysis of full length vsp9B10A-3XHA transcripts in untreated Glvsp9B10A-3XHA cell lines (lane 1), in cell lines treated with Apicidin (lane 3), M344 (lane 5), NaPB (lane 7), splitomicin (lane 9) and TSA (lane 11). RT-PCR of full length transcripts of GleIF4A (lanes, 2, 4, 6, 8, 10, and 12) was used as an internal control.
were observed (data not shown). These partial amplicons could represent the intermediates of degraded vsp1267 transcripts. Interestingly, no full length amplicons were detected when the cells were treated with apicidin or TSA (Fig. 2a, lanes 3 and 9) and the results were consistent in 7 independent treatments performed on different days. These results agree with the previous reports that showed a decrease in the expression of vsp1267 upon treatment with TSA [4] or no change in expression when treated with apicidin [9]. Both untreated control and HDAC inhibitor treated cells showed a full-length GleIF4A amplicon of 1.2 kb (Fig. 2a, lanes 2, 4, 6, 8, 10 and 12).

In contrast to vsp1267-3XHA, full length vsp9B10A-3XHA amplicon of 2.2 Kb was detected in Glvsp9B10A cell lines that were treated with splitomycin or trichostatin A (Fig. 2b, lanes 9 and 11, respectively) but not in cell lines treated with apicidin, M344 or NaPB (Fig. 2b, lanes 3, 5, and 7, respectively). However, a smear of amplicons ranging from 0.5 to 1.5 Kb was observed in untreated control and in Apicidin, M344 or NaPB treated cells but not in cells treated with splitomicin or TSA. These amplicons may represent the intermediates of transcripts degraded by RNAi and/or miRNA mediated mechanisms [4, 5]. Both in untreated control and treated cell lines, the expression of the internal control gene GleIF4A was detected (Fig. 2b, lanes 2, 4, 6, 8, 10 and 12).

**Effect of HDACi on parasite growth**

Replicating trophozoites of Glvsp1267-3XHA cell lines were treated with 2 µM of HDAC inhibitors for up to 48 h. After 24 h, no significant growth inhibition was observed in the cell lines treated with all the inhibitors when compared to control (Fig. 3). However, after 48 h of treatment, Apicidin inhibited the parasite growth by 87% (P < 0.001%), while Trichostatin A inhibited the growth by 82.2% (P < 0.001%) when compared to the untreated controls. However, there was no significant decrease in the growth of the parasites when treated with M344, NaPB, or splitomicin, when compared to the untreated controls (Fig. 3). These results suggest that the changes in the expression of vsp1267-3XHA (Fig. 2a) observed after 24 h of HDAC inhibitor treatment were not due to cell toxicity.

**Discussion**

In this study, we demonstrated that tagging a chromosomal copy of a vsp gene can be used to monitor its expression in the presence of histone deacetylase inhibitors. Since the genes are tagged with 3XHA epitope at the 3’ end, the 5’ end is not disrupted [8]. Thus, it maintains the native chromatin environment at the promoter region for the epigenetic mechanisms to operate. Also, tagging the 3’ end does not necessarily interfere with the RNAi and miRNA mediated silencing mechanisms as they target the coding sequences of vsp mRNA in *Giardia* [4, 5].

Due to the unavailability of monoclonal antibodies, we were not able to confirm the variant of vsp that is being expressed by *Giardia* WB cells before generating 3XHA tagged cell lines. Since we did not detect the expression of the tagged vsps (vsp1267 and vsp9B10) in untreated controls, we assume that these cell lines (Glvsp1267-3XHA and Glvsp9B10-3XHA) are probably expressing a different variant of vsp at the time of treatment with HDAC inhibitors. Although we were able to detect the expression of the tagged vsp transcripts in treated cells, but not an untagged vsp, we cannot yet dismiss the possibility that these cells may have switched the vsp gene from an unknown variant to the tagged vsp.

In our experiments, we have detected the expression of tagged vsps in cell lines treated with splitomicin more often than treated with TSA, Apicidin, M344, and NaPB, when compared to untreated controls. Apicidin [10], TSA [11], NaPB [12], and M344 [13] are known to inhibit NAD+ independent histone deacetylases that belong to class I HDACs. A homologue of class I HDAC has been identified in the *Giardia* genome database and previous reports have indicated that this enzyme can be inhibited by TSA, Apicidin, and NaPB [6, 8]. In agreement with the previous reports [6, 8], we have observed growth inhibition of the parasites within...
48 h of treatment with TSA and Apicidin. Although M344 and NaPB are known to target the same HDAC I enzyme, they did not inhibit parasite growth even after 48 h of treatment. These results suggest that growth inhibition by TSA and Apicidin could be due to the inhibition of other essential cellular processes in addition to the inhibition of HDAC I enzyme [8]. Previous reports have indicated that treatment with TSA leads to an increase in the association of H3K9ac, H4K8ac and H4K16ac with the 5′ upstream sequences of expressed vsps [6], as HDAC I enzyme is known to target these acetylated histones. Based on these observations, we speculate that induction of vsp1267-3XHA with M344 and NaPB, and vsp9B10A-3XHA with TSA, could be due to hyperacetylation of these histones associated with the 5′ upstream elements.

Although vsp1267-3XHA and vsp9B10A-3XHA respond similarly to splitomicin [14] (inhibitor of Class III HDACs) treatment, they differ in their response to NaPB, M344 and TSA (inhibitors of Class I HDACs) treatments. It has been demonstrated that cancer cells display a differential response to apicidin, depsipeptide and TSA, and these differences in response were attributed to inhibitors targeting protein factors other than inhibiting HDAC activity in the cells, such as lowering global levels of histone methylation [15]. Therefore, it is likely that HDAC inhibitors could be targeting other proteins involved in gene expression. Alternatively, the chromatin environment at the promoter elements of vsp1267-3XHA and vsp9B10A-3XHA may be different, resulting in differences in the responses to various HDAC inhibitors.

Limitations

Although tagging the 3′ end allowed us to qualitatively monitor the full-length transcripts using RT-PCR, it is not ideal for accurately estimating the transcript levels using qPCR as it requires amplification of small regions of ~200 nucleotides in order to accurately estimate transcript levels [16]. Due to RNAi and miRNA mechanisms, short mRNA intermediates are generated and these intermediates could be potentially amplified by RT-qPCR.

Abbreviations

HA: Hemagglutinin; NaPB: Sodium phenylbutyrate; TSA: Trichostatin A; HDAC: Histone deacetylase; HDACi: Histone deacetylase inhibitors.
