**Abstract**

Vitamin $B_{12}$ deficiency usually mimics megaloblastic anemia, pancytopenia, neurological symptoms and, rarely, hemolytic anemia. This report describes a case with symptoms of apathy and findings suggestive of severe hemolytic anemia, diagnosed with vitamin $B_{12}$ deficiency. Haemolysis is a rare hematological finding in cases of $B_{12}$ deficiency, and descriptions of a nutritional vitamin $B_{12}$ deficiency, without evidence of pernicious anaemia, causing haemolysis, are even scarcer, and this paper was intended to draw physicians’ attention to this rare form of presentation.

**Keywords:** Haemolytic anaemia; Vitamin $B_{12}$; Cobalamine; Vitamin deficiency; Nutritional anaemia

**Introduction**

Once encountered with anaemic patient, clinical findings, erythrocytes indexes and peripheral blood smear results are preferred initial parameters, in algorithmic approach towards diagnosing of the cause of anaemia. However, if different aetiologies’ are present or with atypical presentations, that mask the clinical scenario, the case becomes complex and difficult to diagnose. Similar was the scenario with the under stated patient, where, though there was a deficiency of vitamin $B_{12}$, erythrocyte indexes were compatible with microcytic to normocytic anaemia with normal red cell distribution width (RDW) in the background, and an exaggerated rise in LDH, reticulocyte counts & indirect bilirubin was seen, as if haemolytic anaemia.

**Case**

A 47-year-old vegetarian male with no reported past medical history presents with complaints of progressive weakness, lethargy, headache and light-headedness over the course of the last 3 months. Additionally, the patient reports that during the course of the last 3 months he had been having an increasingly difficult time performing daily workplace outdoor responsibilities, due to progressive generalized weakness & light-headedness which improved with ample rest. The patient visited his primary care physician for progressive symptoms and was found to be severely anaemic. He affirmed medical evaluation 6 months back, where he was declared clinically well. He was then referred to the hospital for further evaluation and possible blood transfusion. In the emergency department (ED), his vital signs were: heart rate of 90 beat/minute, blood pressure of 120/70 mmHg, temperature of 97 degrees Fahrenheit, respiratory rate of 18 breaths/minute, and pulse oximetry of 97% on room air. The physical examination showed mucosal and conjunctival pallor, no scleral icterus, no palpable lymph nodes, non-distended abdomen, normal bowel sound with no organomegaly, and unremarkable cardiac and lung examination. Neurological examination findings were also normal.

Initial laboratory studies revealed white blood cell count (WBC) of 5,600 (Ref. 4,000-11,000/cumm) with neutrophil accounting 90.5% (Ref. 40-70%), haemoglobin (Hb) 4.8gm% (Ref. 14-18gm%), haematocrit (Hct) 17.2% (Ref. 40-54%), platelets 160,000 (Ref. 140,000-450,000/cumm), and a mean corpuscular volume (MCV) 90.5 (Ref. 76-96fl), mean corpuscular haemoglobin (MCH) 25.3 (Ref. 27-32pg), mean corpuscular haemoglobin concentration (MCHC) 37.9 (31-36%) and reticulocyte count 4 (Ref. 0.2-2%). Erythrocyte sedimentation rate (ESR) was 75mm/hr. Comprehensive biochemical examinations were as follows: urea 30 (Ref. 10-50mg/dl), creatinine 1.0 (Ref. 0.6-1.5mg/dl), Na+ 142 (Ref. 135-145mEq/l), K+ 3.6 (Ref. 3.5-5.5 mEq/l)), aspartate aminotransferase (AST) 31 (Ref. 17-59IU/l), alanine aminotransferase (ALT) 21 (Ref. 21-72 IU/l), alkaline phosphatase (ALP) 52 (Ref. 38-126 IU/l), total protein

Anaemia is usually classified in haemorrhagic, dyserythropoietic & haemolytic types [1], and their diagnosis is usually guided initially by clinical findings and tests like erythrocytes indexes & peripheral blood smears. This patient presented with severe anaemia, and the associated complaints correlated with the clinical scenario. On further evaluation, coexisting hyperbilirubinaemia with elevated indirect bilirubin, high LDH, and multiple fragmented red blood cell noted on peripheral smear indicated erythrocyte destruction or haemolytic anaemia as the cause. Haemolytic anaemia represents a diverse group of diseases which can be divided in to congenital or acquired. Since the patient did not have history of anaemia in the past, and no history of transfusion, no evidence of hepato-splenomegaly, it is unlikely that this is due to inherited conditions. Other confirmatory tests also eliminated the presence of haemoglobinopathy and G6PD deficiency. Peripheral blood smear examination was not a characteristic of spherocytosis or elliptocytosis. There are various causes of acquired haemolytic anaemia including but not limited to autoimmune, drug-induced, microangiopathic haemolytic anaemia, infections, chemicals, nutritional deficiency such as vitamin B₁₂ and folate deficiency, severe burn, and radiation. Due to multiple aetologies, numbers of workup were performed for this patient to rule out different causes of acquired haemolytic anaemia. The possibility of haemolytic anaemia secondary to severe burn or radiation exposure was eliminated since the patient denied such history.

His Coombs test and ANA were negative which argue against autoimmune haemolytic anaemia. Drug-induced or chemical-related haemolysis was also less likely since the patient denied taking any medication and he has no history of chemical-related exposure. Microangiopathic haemolytic anaemia, such as thrombotic thrombocytopenic purpura (TTP), haemolytic uremic syndrome (HUS), and disseminated intravascular coagulation (DIC), is also less likely since the patient has normal platelet count, no renal abnormality, and normal coagulation. Another cause for intravascular haemolysis such as valvular heart disease was also excluded since he does not have murmur on physical examination and prior history of cardiac disease. The likely cause of haemolytic anaemia in this case was due to vitamin B₁₂ deficiency, since serum B₁₂ level was low. Commonly, vitamin B₁₂ deficiency is associated with macrocytic anaemia. However, the patient’s mean corpuscular volume (MCV) and RDW were normal which suggested the presence of other pathology like iron deficiency anaemia, hypothyroidism etc, which was ruled out by normal iron profile and thyroid function test.

Results

In a review of literature, case reports on vitamin B₁₂ deficiency causing haemolytic anaemia are quite rare. Furthermore, descriptions of a nutritional vitamin B₁₂ deficiency, without evidence of pernicious anaemia (normal upper gastrointestinal endoscopy), causing haemolysis are even scarcer. Studies suggest, Vitamin B₁₂ deficiency can present with a haemolytic picture in 1.5% of patients with elevated LDH, low haaptoglobin, and elevated indirect bilirubin mostly due to ineffective erythropoietin and intramedullary destruction [2-4].

The main source of vitamin B₁₂ is animal product such as meat, milk, egg, fish, and shellfish [5]. Hence, strict vegetarians, like this patient, have a greater risk of developing vitamin B₁₂ deficiency [5]. Managing our patient was challenging as he presented with a severe normocytic anaemia and haemolytic picture, none of which were suggesting vitamin B₁₂ deficiency.

The treatment of cobalamin deficiency required replacement of vitamin B₁₂. Daily high dose oral therapy (1000 to 2000 mcg per day) is as effective as parenteral formula in several randomized studies [6]. Our patient was initially treated with intramuscular injection of vitamin B₁₂, followed by oral supplement which showed
significant improvement in symptoms within a week. His Hb and red cell indices continued to improve with complete resolution of haemolysis. Vitamin B$_{12}$ level have normalized. This case displayed the complexity of vitamin B$_{12}$ deficiency where clinicians should be familiar. Once the diagnosis is confirmed, further investigation is warranted to explain the aetiology.
