Background. Globally, one-third of new sexually transmitted infection (STI) cases occur in people under 25 years of age every year. University students are in the youth age category and are exposed to risky sexual behaviors such as unprotected sexual intercourse leading to STIs. Therefore, this study was aimed to assess the prevalence and associated factors of STIs among Jimma University students.

Method. A health facility-based cross-sectional study was conducted at Jimma University students’ clinic from April 2017 to October 2017 among students with STIs syndromes. Urethral, endocervical, and vaginal discharges swabs were collected by attending nurses. Standard protocol was followed to detect the etiologies of STI. Data were entered and analyzed using SPSS Version 20.

Results. The overall prevalence of STIs among clinically suspected university students was 14.3%. The predominant causes of STIs were Neisseria gonorrhoeae (7.4%) followed by Trichomonas vaginalis (4.8%) and Treponema pallidum (3.7%). Having had sex after taking alcohol was significantly associated with STIs (P ≤ 0.000). All N. gonorrhoeae isolates were found to be resistant to penicillin and tetracycline.

Conclusion. In this study, the prevalence of STIs was relatively high. The isolated N. gonorrhoeae was resistant to commonly prescribed antibiotics. Therefore, evidence-based treatment and proper reproductive health education for youth are highly recommended.

1. Introduction

Sexually transmitted infections (STIs) are mainly transmitted from person-to-person through sexual contact [1]. There are several counts of sexually transmissible etiologies from members of bacteria, viruses, and parasites. These are responsible for multiple sexually transmissible diseases such as gonorrhea, chlamydial infection, syphilis, trichomoniasis, chancroid, genital herpes, human immunodeficiency virus (HIV) infection, and hepatitis B infection. Some of the above etiologies can also be transmitted vertically from mother to child during pregnancy as well as through blood products [2]. From all recognized STIs, four of them, namely, syphilis, gonorrhea, chlamydia, and trichomoniasis, have been found to be curable [3].

Sexually transmitted infections are a major cause of acute illness, infertility, long-term disability, and death with serious medical and psychological consequences of millions of individuals [2]. Both ulcerative and inflammatory curable STIs increase the risk of acquiring and transmitting HIV by up to two- to threefold [4]. Globally, one-third of over 340 million new STI cases occur per year in people under the age of 25 years. In developing countries particularly in sub-Saharan Africa, the burden of STI is very high with 108 million STIs occurring every day. It is estimated that 80 to 90% of the global burden of STIs occur in those low-income countries, where there is limited or no access to diagnostic facilities and poor awareness [5].

About 35% of Ethiopian population comprised young people between 15 and 24 years of age, and this largest category is highly vulnerable to STIs [6, 7]. In a STI surveillance study conducted in 8 health facilities in various regions of Ethiopia, younger people in the age group of 20–34 years were among highly affected ones (68.2%) [8]. Most university students are in the youth age category and are exposed to risky sexual behaviors which lead to acquiring STIs [9]. According to a cross-sectional study conducted in
one of the universities in Ethiopia, the prevalence of self-reported STIs was 19.5% among university students [10].

Even though few studies on STIs were done in Ethiopia, there are no adequate data about the prevalence and associated risk factors of *N. gonorrhoeae*, syphilis, and *T. vaginalis* infection and antimicrobial susceptibility patterns of *N. gonorrhoeae* isolates among university students in Ethiopia. Therefore, this study was aimed to determine the prevalence of STIs specifically *N. gonorrhoeae*, *T. pallidum*, and *T. vaginalis* infection and their associated risk factors and antimicrobial susceptibility patterns of *N. gonorrhoeae* among Jimma University students.

2. Methods

2.1. Study Design and Period. A health facility-based cross-sectional study was conducted from April 1, 2017, to October 5, 2017, at Jimma University students’ clinic. Jimma University is located in Ethiopia and 352 km far from the capital. It serves for more than 30,000 students in different programs.

2.2. Sample Size. All students who came to student clinic with STI syndromes in the study period were included except students who took antibiotics or antiprotozoan treatment two weeks prior to enrollment in the study. Therefore, a total of 189 university students participated in the study.

2.3. Data Collection

2.3.1. Sociodemographic and Sexual Behavior. A pretested structured self-administered questionnaire was used to collect data on sociodemographic and risky sexual behaviors.

2.4. Laboratory Data

2.4.1. Specimen Collection and Processing. Two cervical swabs and one vaginal swab were taken from female students, while three urethral swabs were taken from male students by attending nurses. The first cervical or urethral swab was inserted aseptically in the Amies transport medium to transport to Jimma Medical Center Microbiology Laboratory where isolation, identification, and antimicrobial susceptibility testing were done for *N. gonorrhoeae*. The second cervical or urethral swabs were smeared and gram stained for microscopic examination. The last vaginal swab or urethral swab was added to a tube containing sterile 0.5 ml physiologic saline for wet-mount preparation to identify *T. vaginalis*. Three to five milliliters of venous blood were collected into anticoagulant-free sterile tubes for serological screening of *T. pallidum* infection using One Rapid immunochromatographic test kit (Inc., China).

The first cervical or urethral swabs transported with Amies transport medium were inoculated on the Modified Thayer Martin medium (Oxoid, England) and incubated at 35–37°C in the presence of 5% CO₂ for 24–72 hours and examined for the presence growth every 24 hours of incubation. If growth was observed, single colony was taken and subcultured on a GC-chocolate agar supplemented with 1% Vitox (Oxoid, England) and incubated in similar fashion. To identify the pathogen, gram staining and standard biochemical tests (oxidase, superoxol, and carbohydrate utilization tests) and Analytical Profile Index for identification of *Neisseria* and *Haemophilus* (API NH) kit strips (bioMerieux, France) were used [11].

2.4.2. Antimicrobial Susceptibility Testing. From the GC-chocolate agar culture medium, 3–5 isolated colonies of bacteria were transferred and added to a tube containing 2.5 ml sterile normal saline until the turbidity of the suspension becomes comparable to 0.5 McFarland standard. The bacterial suspensions were swabbed evenly to distribute the bacteria over the entire surface of GC-chocolate agar with 1% Vitox supplement using a sterile swab. The antimicrobial susceptibility patterns of isolates were assessed to the following antimicrobial agents: penicillin (P10 IU), tetracycline (TE, 30 μg), ciprofloxacin (CIP, 5 μg), ceftriaxone (CRO, 30 μg), cefixime (CFM, 5 μg), and cefoxitin (FOX, 30 μg) (all from Oxoid, England) according to CLSI guidelines [12].

2.5. Quality Control. Culture media were tested for sterility before being used to process the clinical specimen and recovery rate using standard reference strain of *N. gonorrhoeae* ATCC 49226 to isolate the intended microbes and to perform antimicrobial susceptibility testing of gonococcal isolates according to CLSI guidelines [12].

2.6. Data Analysis. Data were entered into Epi data software version 4.0 and exported to SPSS version 20.0 for statistical analyses. Descriptive statistics and chi-square tests were carried out. Bivariate and multivariate logistic regressions were employed to determine the risk factors of STIs, and a P value ≤0.05 was taken as statistically significant.

2.7. Ethical Consideration. Ethical clearance was obtained from Jimma University, Institutional Review Board. Support letter was obtained from school of medical laboratory sciences and student service dean of Jimma University. Written informed consent was obtained from each participant. All the laboratory test results were given for treating physicians for beneficiary of the patients.

3. Results

A total of 189 university students suspected for sexual transmitted infections were included in the study with 100% response rate. Fifty-eight (30.7%) students were males, and three-fourth were twenty or greater than twenty years of age. The distribution of the students across the university institute or college appeared fairly uniform between 22.2% and 27.5%. Forty-nine (29.5%) university students were first year, whereas the remaining were second year and above.
From the total of 189 students suspected for STIs, 27 (14.3%) of them were infected by one or more of the three etiologies. The prevalence of *N. gonorrhoeae*, *T. pallidum*, and *T. vaginalis* was 7.4% (14/189), 3.7% (7/189), and 4.8% (9/189), respectively. Two patients were coinfected with *N. gonorrhoeae* and *T. pallidum*, and another one patient with *N. gonorrhoeae* and *T. vaginalis*. Of the 14 patients who were confirmed to have gonococcal infection, nine (15.5%) were males and five (3.8%) were females. Of all study participants infected with *T. vaginalis*, nine (6.9%) were females. There was no male patient positive for *T. vaginalis*, and three (5.2%) males and four (3.1%) females were infected with *T. pallidum* (Table 1).

In this study, the susceptibility pattern of gonococcus was done against six antimicrobial agents and showed that 85.7% of the isolates were susceptible to ceftriaxone and cefixime. On the contrary, 78.6% and 50% of the isolates were susceptible to cefoxitin and ciprofloxacin, respectively. Intermediate resistance was observed in 28.6% and 14.3% of the isolates against ciprofloxacin and cefoxitin, respectively. All gonococcus isolates were found to be resistant to penicillin and tetracycline (Figure 1).

To assess the risk factors for sexually transmitted infection, both bivariate and multivariate logistics regression analyses were done. From sexual behavior and substance use, having more than one sexual partner, having had sex after taking alcohol, and khat chewing were the candidate variables for multivariate logistic regression analysis. Finally, in the multivariate logistic regression analysis, only patients who had sex after using alcohol were independently associated with sexually transmitted infections ($P \leq 0.000$) (Table 2).

### 4. Discussion

This study provides the prevalence and associated risk factors for STIs (*N. gonorrhoeae*, *T. vaginalis*, and *T. pallidum*) among Jimma University students suspected for sexually transmitted infections. The overall prevalence of STIs was 14.3%. In the present study, the cause of most prevalent sexually transmitted infection was *N. gonorrhoeae* (7.4%), which is higher than the studies reported from Hawassa (5.1%) [13], Port Harcourt Rivers state (5%) [14], and Abuja University (2.9%) [15] and lower than the studies reported from Gambella (11.3%) [16], Jimma (17.2%) [17], Gondar (20.8%) [18], Southern Mozambique (14%) [19], and Uganda (59%) [20]. The variation in prevalence rate might be because of variation in study population.

In this study, the prevalence of gonococcal infection was significantly higher in males (15.5%) than females (3.8%). This finding is comparable with the finding from Gambella in Ethiopia [16]. This is likely because gonococcal infections are more symptomatic in males than females that may take them for health-seeking decision.

In the present study, the second prevalent STI etiology was found to be *T. vaginalis* (4.8%), which is similar with the finding reported from Abuja University (4.7%) [15] and lower than the studies reported from Babcock University (12.5%) [21] and Brazil (9%) [22]. On the contrary, the prevalence of this study is higher than the study conducted in Nairobi (0.4%) [23]. The observed difference in the rate of infection could be due to variation in the age distribution and personal hygiene practice. All students with *T. vaginalis* were females, and similar finding was reported from Abuja.
Female patients are more symptomatic to this protozoan vaginosis than males. On the contrary, the prevalence of *T. pallidum* infection was 3.7% which is higher than the one reported from Addis Ababa (0%) [24], Jigjiga (0.1%), [25] and Abuja 2.4% [15]. The target population in Addis Ababa study was women who attended antenatal follow-up and healthy blood donors in the Jigjiga study. On the contrary, the prevalence of *T. pallidum* in the current study is lower compared with the study in Beijing (7%) [26], Zambia (6.5%) [27], and Nigeria (15.4%) [28]. The variation in the prevalence rate of infection may be due to differences in target population.

In the present study, complete resistance to penicillin and tetracycline was reported which was similar to reports in Gambella [16] and India [29]. Such resistant features may be due to beta-lactamase producing *N. gonorrhoeae* strains. The bacteria also showed about 20% resistance to ciprofloxacin which is in line with the reported results from Hawassa (28%) [13], Gambella (18%) [16], and Uganda (23%) [20]. This might be because of the intensive use of ciprofloxacin antimicrobial agent as part of the guideline in syndromic management of gonococcus without evidence. Cefoxitin was found to be effective in 78.6% of the isolates although it is relatively lesser than that reported from Hawassa (82%) [13] and Gambella (100%) [16].

In this finding, *N. gonorrhoeae* showed 14.3% resistance to ceftriaxone, which is lower than the studies reported from Bahir Dar (27.8%) [30], Southern Ethiopia (33.3%) [31], and India (40%) [29] and total resistance in Iran [32]. Multidrug resistance was observed in all *N. gonorrhoeae* isolates. Currently, extensively drug-resistant *N. gonorrhoeae* strains have been reported in Japan [33], France [34], and Spain [35] that displayed a high level of resistance to cefoxime and ceftriaxone. In our study, having had sex after taking alcohol showed significant association with STIs. *N. gonorrhoeae* has shown increased resistance to third-generation cephalosporins like ceftriaxone and cefixime. Evidence-based treatment and continuous antimicrobial resistance surveillance are highly recommended. Proper education on reproductive health for university students has invaluable importance to prevent sexually transmitted infections.

### Data Availability

The data used to support the findings of this study are included in the manuscript and are available from the corresponding author on reasonable request.

### Disclosure

All the data used to support the findings of this study are included in the manuscript.

### Conflicts of Interest

The authors declare that there are no conflicts of interest.

### Authors’ Contributions

RT, TK, ZS, and MG participated in design, write-up, analysis, and interpretation of data. RT and MG participated in data collection, laboratory work, and prepared the manuscript. All the authors reviewed and approved the final version. All authors read and approved the final manuscript.

### Acknowledgments

We are grateful to Jimma University for the financial support to conduct this research. We thank the study participants for their willingness to be part of this study.
