Abstract

The coronavirus disease 2019 (COVID-19) is a highly contagious novel infection that predominantly presents with fever and respiratory symptoms. However, COVID-19 can masquerade as an acute coronary syndrome, leg pain or swelling with venous thrombosis, loss of consciousness with cerebral venous thrombosis, confusion, limb weakness with brain infarction, facial neuralgia, acute conjunctivitis, acute appendicitis, and testicular pain. We report on a 42-year-old man who presented with mild symptoms of COVID-19. The patient’s electrocardiogram showed an ST-segment elevation myocardial infarction (STEMI) due to a left coronary thrombosis. The patient was managed conservatively with medicines and had an uneventful recovery. Emergency physicians should have a high index of suspicion for the unusual presentations of COVID-19.

Keywords: Abdominal pain; Acute coronary syndrome; COVID-19; Unusual presentations; Venous thrombosis

Introduction

The novel coronavirus disease 2019 (COVID-19) is a highly contagious disease that originated in Wuhan, China in December 2019. The disease is caused by infection with the novel severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2). The World Health Organization declared a global pandemic in March 2020.1 COVID-19 patients...
Figure 1: Serial electrocardiogram (ECG) showing a) normal sinus rhythm with left ventricular hypertrophy detected using aVL voltage and ST elevation in V3 to V6, and b) normal sinus rhythm with left ventricular hypertrophy detected using aVL voltage and slight ST elevation in V3 to V5 (improvement after two days of treatment).

Figure 2: Selected images of a left CAG a) cranial view and b) caudal view showing a large thrombus in the LAD artery (arrows).
typically present with fever, cough, myalgia, or fatigue. Less common features are sputum, headache, haemoptysis, and diarrhoea. Some patients may develop dyspnoea and need intensive care. Anosmia and loss of taste are atypical symptoms that have been reported in some cases. Patients may present with unusual or atypical clinical features that are not related to the respiratory system, which may mislead the diagnosis of COVID-19. COVID-19 can present with or be complicated by several extrapulmonary manifestations like thrombosis, myocardial problems, acute coronary syndrome (ACS), acute renal injury, hepatocellular injury, gastrointestinal symptoms and signs, elevated blood sugar problems, neurological manifestations, ocular symptoms and signs, and dermatological features.

In our case, we report on a COVID-19 patient with atypical presentation. This work aimed to highlight the unusual, atypical, and strange clinical presentations of COVID-19 to alert physicians about them, especially during the ongoing pandemic. A brief literature review was performed using a PubMed search for the term “unusual presentation of COVID-19.” The review included published case reports available through PubMed in the English language from January 2020 to August 2020.

Table 1: The literature review includes case reports of COVID-19 with atypical and unusual presentations reported in medical journals indexed in PubMed during the period of the pandemic from January 2020 to August 2020.

| Author(s)          | Age | Gender | Presentation                          | Medical imaging findings                  | RT-PCR |
|--------------------|-----|--------|---------------------------------------|------------------------------------------|--------|
| Kaur et al.        | 43-y-o | Male  | Acute right leg pain with shortness of breath and fever for a week | CXR → bilateral hazy infiltrates  
CTA → Thrombus in right proximal superficial femoral artery | +ve     |
| Davoodi et al.     | 57-y-o | Female | Painful swelling and redness of left leg | CXR → bilateral patch GGO  
CTA → unremarkable Doppler → left lower limb DVT | +ve     |

On the tenth day, chest pain attacks increased, ECG showed ST elevation and biphasic T inversion with poor R progression in V3 to V6. The patient was diagnosed as ST-segment elevation myocardial infarction (STEMI) and referred to a catheter laboratory (Cath lab) for possible primary percutaneous coronary intervention (PPCI) according to the local guidelines of STEMI during COVID-19. Coronary angiography through a right femoral approach was done, revealing a large thrombus in the middle left anterior descending (LAD) artery with post-interventional thrombolysis in myocardial infarction (TIMI) flow 3 and no significant stenosis (Figure 2a and b). The left circumflex coronary artery and the right coronary artery (RCA) were normal. The patient was managed conservatively with Aspirin, Clopidogrel, beta blockers, Tirofiban, and low dose Heparin infusions for 72 h and continued on Enoxaparin for seven days. A follow up ECHO showed no...
new abnormalities, with normal systolic function and an EF of 69%.

On the twentieth day, a follow-up coronary angiogram (CAG) showed partial resolution of the left anterior descending (LAD) artery thrombus with residual particles in situ (Figure 3). The patient continued with triple treatment, with Aspirin, Clopidogrel, and Apixaban, and a CAG was arranged for after two months.

Discussion

SARS-CoV-2, which causes COVID-19, usually presents with fever and respiratory symptoms. However, it may present with unusual or atypical clinical features that are not related to the respiratory system and may mislead from a COVID-19 diagnosis. In this case report and brief review, we focused on the unusual and atypical clinical presentations of COVID-19. In the literature, we found cases reported with unusual or atypical presentations, like leg pain or swelling with venous thrombosis,6–8 loss of consciousness with cerebral venous sinus thrombosis,9 confusion,10 acute conjunctivitis,11,12 left facial drop and arm weakness with brain infarction,13 facial neuralgia with herpes zoster,14 right iliac fossa pain like appendicitis,15 and abdominal pain accompanied by testicular pain16 (Table 1).

In this paper, we reported a case of COVID-19 that was diagnosed early with mild respiratory symptoms and then complicated with coronary thrombosis and typical myocardial infarction features. A similar case of STEMI with coronary thrombosis was reported by Shams et al. and successfully managed with PPCI.17 Salido-Tahoces et al. reported another positive case of COVID-19 in a 62-year-old male who presented with asthenia and recurrent chest pain with ACS and proximal RCA stenosis and whose diagnosis was confirmed by CAG.18 Similarly, Tedeschi et al. reported acute STEMI with a large coronary thrombosis in a 60-year-old man; they explained this by pointing to the presence of high levels of post-inflammatory mediators in patients with COVID-19.19 In addition, Harari et al. reported acute myocardial infarction (AMI) with extensive coronary thrombosis in a 40-year-old

COVID-19: Coronavirus disease 2019, SARS-COV-2: severe acute respiratory syndrome coronavirus-2, RT-PCR: reverse transcriptase-polymerase chain reaction, CXR: chest x-ray, CT: computed tomography, CTA: CT angiography, GGO: ground-glass opacity, DVT: deep venous thrombosis, NA: not available, -ve negative, +ve positive, y: year, o: old.
female. SARS-CoV-2 infections can cause harmful myocardial complications that include myocardial injury, arrhythmia, myocarditis, cardiomyopathy, arterial and venous thrombosis, cardiogenic shock, and even cardiac arrest. AMI’s pathogenesis is complex, still incompletely understood, and sometimes explained by the uncontrolled release of post-inflammatory cytokines (cytokine storm) and the direct damage of cardiac myocytes due to hypoxemia or the virus itself. Ultimately, severe acute viral infection itself can promote the formation of ACS by increasing the risk of plaque rupture and micro-thrombi, owing to systemic inflammation or a cytokine storm, or by causing hypoxemia and coronary spasm, leading to a decreased oxygen supply to the myocardium.

**Conclusion**

COVID-19 patients can present to emergency departments with vascular complications like acute coronary syndrome, as in the current case report. Other unusual and atypical presentations that have been reported include leg pain or swelling with venous thrombosis, loss of consciousness with cerebral venous thrombosis, confusion, acute conjunctivitis, limb weakness with infarction, facial neuralgia, right iliac fossa mimicking appendicitis, or testicular pain. Emergency physicians should be alert to the unusual presentations of COVID-19 during the pandemic.
