Abstract

Nowadays, green synthesis of metal nanoparticles has become a promising synthetic strategy in nanotechnology and materials sciences. In this research, biosynthesis of silver nanoparticles (AgNPs) was successfully accomplished in the presence of Prosopis farcta fruit extract as a reducing agent. Proceeding of the reaction was assessed by using UV–vis spectroscopy. Characterization of silver nanoparticles was carried out by X-ray Diffraction spectroscopy (XRD) and transmission electron microscopy (TEM). The influence of process variables such as temperature, reaction time, and extract concentration was also investigated to optimize the biosynthesis of silver nanoparticles. The average size of synthesized AgNPs was 12.68 nm (10.26-14.65 nm). Furthermore, fruit extract and AgNPs were evaluated for total phenolic and flavonoid contents and were subjected to determine their antiradical scavenging activity using 1,1-diphenyl-2-picryl-hydrazyl (DPPH) and ferric reducing antioxidant power (FRAP) assay and antimicrobial activity against Staphylococcus aureus, Streptococcus pneumonia, Escherichia, Salmonella typhi using the disk diffusion method. The total phenols and flavonoids in AgNPs-containing plant extract were 462.69 (mg GAE/g extract) and 386.94 (mg QE/g extract) respectively, which were significantly higher than fruit extract. Biosynthesized AgNPs showed a higher antioxidant and antibacterial activity compared to P. farcta fruit extract alone. It could be concluded that P. farcta fruit extract can be extensively used in the production of potential antioxidant and antibacterial AgNPs for biomedical application.

Keywords: Antioxidant activity; Antibacterial properties; Prosopis farcta; Silver nanoparticles.

Introduction

Nanotechnology has been emerged as one of the most active fields of research in material science over the last decades. The fact that nanoparticles (NPs) exhibit a number of interesting and unique properties owing to their specific characteristics, such as size, distribution and morphology, leads themselves to a wide variety of applications (1). Among noble metal nanoparticles, silver nanoparticles (AgNPs) have a wide area of interest since they have too many applications in different fields such as in the fields of dentistry, clothing, catalysis, mirrors, optics, photography, electronics, and the food industry. Because of these applications, many methods for synthesis of AgNPs have been

\textsuperscript{*} Corresponding author:
E-mail: esmaeilzadeh@uoz.ac.ir
developed. These methods must have capable
to control the size of AgNPs. Therefore, the
AgNPs with small particle size and without
bulking between particles is favorable (2).
Recently, several chemical and physical routes
and green synthesis are known for preparation
of metal nanoparticles (3). However, many of
these routine methods are very costly and toxic
to the environment (4). On the other hand,
the biological method was reported as clean,
non-toxic and environmentally acceptable route
(5, 6). In this regard, the use of plants and its
extracts as reducing agents for the production
assembly of AgNPs is very feasible, cost-
effective, and eco-friendly (7). Biomolecules
like protein, phenols, and flavonoids in plants
not only play a role in reducing the ions to
nano size, but also play an important role in
capping of nanoparticles (8). Fruit extracts
from various plants have been used to produce
AgNPs, such as Nothapodytes nimmoniana (9),
Crataegus douglasii (10), Garcinia mangostana
(11), Averrhoa carambola (12), Lantana camara
(13), Emblica officinalis (14). Prosopis farcta
(Leguminosea family) is a native plant of United
States, northern Africa, and Asia (15). It grows
in southern Iran in the Sistan and Baluchestan,
Hormozgan, Bushehr, Khuzestan and southern
Fars provinces (16). P. farcta is a good source
of phenolic compounds and flavonoids such as
rutin, myricetin and caffeic acid derivatives (17).
P. farcta have been used as a traditional medicine
for the treatment of some diseases and disorders.
Antioxidant capacity (18), antimicrobial (19),
and antitumour activity of this plant (20) have
been reported recently. Hence, in the present
study we have demonstrated biosynthesis of
AgNPs by reduction of aqueous silver nitrate
(AgNO3) using P. farcta aqueous fruit extract
for their potential antioxidant and antibacterial
effects.

Experimental

Chemicals
Silver nitrate (99.98%), ammonium
hydroxide (25%), hydrochloric acid (37%)
and nitric acid (70%) were purchased from
Merck Company (Darmstadt, Germany).
1,1-diphenylpicrylhydrazyl (DPPH) was
purchased from Sigma Aldrich. All chemical
materials were of analytical grade and were used
without any further purification. All solutions
were freshly prepared using double distilled
water and were kept in darkness to avoid any
photochemical reactions. All glass ware which
were used in the process, were washed with
acetone, and then with double distilled water
and dried before use.

Plant extract
Biosynthesis of silver nanoparticles
P. farcta fruits were collected in June 2015,
from Zabol, Sistan, and Baluchestan province,
Iran. The fresh fruits were thoroughly washed
with deionized water for several times and then
dried. 2.5 g of fruit was added to 100 mL of
distilled water and boiled in for 30 min. The
prepared suspension was filtered by Whatmann
No. 40 filter paper. The resultant solution was
centrifuged at 4000 rpm for 30 min in order to
remove impurities. 9 mL of 0.001 M aqueous
solution of silver nitrate (AgNO3) was prepared
in a stoppard erlenmeyer flask and then different
volumes (100, 110, 120, 130, or 140 µL) of
fruit extract (2.5 g/100 mL) was added to the
flask at room temperature in darkness. To study
the influence of temperature on nanoparticle
synthesis, the reaction mixtures were incubated
in a rotary shaker at 150 rpm at 50, 60 or 70
°C for a period of time. After the reaction was
completed, the mixture was centrifuged for 20
min at 15000 rpm. The precipitate was washed
with distilled water and centrifuged several
times in order to remove impurities like starting
material or natural products which still remained
from extract. The influence of reaction time was
evaluated by incubating the reaction mixtures
with optimum composition for 25 or 45 min.

Optimization study
In order to optimize the synthesis of AgNPs,
the influence of every variable on the reaction
process including reaction temperature, extract
concentration (volume) variation, and the
reaction time were evaluated separately, as one
variable held constant and the others varied.

Influence of extract concentration
Different volumes of aqueous fruit extract of
P. farcta (100, 110, 120, 130 and 140 µL) were selected after preparing the extract by boiling freshly cut fruits in deionized water for 2 min. Then, AgNO₃ (0.001 M) solution was added and incubated for 4 h in rotatory shaker at 150 rpm.

**Influence of reaction temperature**

In order to find the influence of reaction temperature on the biosynthesis of silver nanoparticles, different concentrations of aqueous fruit extract of *P. farcta* at different reaction times were investigated for three temperatures of 50, 60, and 70 °C separately.

**Characterization**

**UV-vis analysis**

The absorption spectrum of the reaction mixture was recorded at room temperature by using UV–vis spectrophotometer (Rayleigh, UV-2100) at the resolution of 1 nm.

**XRD analysis**

The structure of silver nanoparticles was determined by X-ray diffraction using the Bruker – D8 Advanced (Germany) instrument. A wavelength (λ) 0.15418 nm was used for these analyses. The XRD patterns were recorded at the scan speed of 2° min⁻¹.

**TEM analysis**

Transmission electron microscopy (TEM) (Jeol JSM 2010) was recorded on a JEM-2100 with an accelerating voltage of 200 kV equipped with a high resolution CCD Camera. To prepare the samples for TEM analysis, a grid was first covered by a gold film and a small amount of the sample was dispersed in 20 mL of ethanol by sonication for 20 min, and then the grid was treated with the solution.

**Determination of total phenol content**

Total phenolic content was measured with the Folin–Ciocalteu (21). 0.1 mL of extract at appropriate dilutions was added to a mixture of 0.5 mL of Folin–Ciocalteu reagent and 0.4 mL of 7% Na₂CO₃ solution. The absorbance was measured at 765 nm, after incubation for 30 min in dark. The results were expressed as mg Gallic acid equivalents per gram of dry weight (mg GAE g⁻¹ extract dry weight) through the standard curve with Gallic acid.

Total flavonoid content was measured according to the aluminum chloride colorimetric method as described by Chang et al., 2002 (22). 500 µL of aqueous extract, 1.5 µL of methanol (80%), 10% aluminum chloride (0.1 mL), 1 M potassium acetate (0.1 mL) and distilled water (2.8 mL) were mixed and incubated at room temperature for 40 min. Then, the absorbance was measured at 415 nm using spectrophotometer. Quercetin was used as a standard. The content of total flavonoids was expressed based on the mg quercetin per gram of extract dry weight.

**Determination of antioxidant activity**

**DPPH radical scavenging activity**

The biosynthesized AgNPs and the aqueous fruit extract were tested for their antioxidant activity by DPPH method (23). Each extract (0.2, 0.4, 0.6, 0.8 or 1 mg/mL) was mixed with 3 mL of methanolic solution containing DPPH radicals (0.1 mM). After 30 min, absorbance was determined at 517 nm. The percent inhibition of activity was calculated as \([\frac{A_o - A_e}{A_o}] * 100\) (Ao = absorbance without extract; Ae = absorbance with extract). The results were expressed as IC50 which is the concentration of the sample required to inhibit 50 % of DPPH concentration.

**Ferric reducing antioxidant power (FRAP) assay**

FRAP assay was performed as previously described (24). The method is based on the ability of antioxidants to reduce Fe³⁺ to Fe²⁺ in the presence of TPTZ (2, 4, 6-tripyridyl-s-triazine), forming an intense blue Fe²⁺–TPTZ complex. FRAP solution (3 mL) mixed with 100 µL of the plant extract and incubated at 37 °C for 10 min. The absorbance was measured at 593 nm for different concentrations (0.2, 0.4, 0.8 or 1 mg/mL) of AgNPs and extract in FRAP reagent. The absorbance of the samples was compared to a FeSO₄ standard curve and the FRAP values were expressed as mmol Fe (II)/mg extract.

**Antibacterial activity**

Antibacterial activity of the prepared fruit extract and AgNPs was evaluated using disk diffusion method (25) against common Gram
positive bacteria, i.e., *Staphylococcus aureus* (Bristol A9596), *Streptococcus pneumoniae* (NCTC 7465) and Gram-negative bacteria, i.e., *Escherichia coli* (ATCC 25922), *Salmonella typhi* (PTCC 1609). The pure bacterial cultures were cultured on nutrient broth. The plates were left overnight at room temperature to allow any contamination to appear. Sterile paper disks were placed on Muller Hinton agar plates inoculated with each of the mentioned microorganisms. 1 mg/mL and 5 mg/mL of Ag-NPs and fruit extracts were placed on inoculated agars. The test plates were incubated at 37 °C for 24 h. The zones of inhibition were measured and numbers reported in average (Table 3). Gentamicin was used as an antibacterial standard against all pathogens.

**Results and Discussion**

Reduction of Ag⁺ into silver nanoparticles during exposure to the *P. farcta* fruit extract could be observed by the color change. The color of fresh prepared fruit extract of *P. farcta* was yellow. After the addition of AgNO₃ to the extract and incubation for 6 h in a rotary shaker at 150 rpm, the extract color was turned dark brown (Figure 1). Color changes in aqueous solutions are due to the surface plasmon resonance phenomenon (25). The results were shown that the fruit extract of *P. farcta* is a good potential reducing agent for Ag⁺ ions. In accordance with the results of Shameli *et al.* (26), plausible chemical equations for the biosynthesis of silver nanoparticles are followings:

\[
\text{Ag}^+ (\text{aq}) + P. \text{farcta} (\text{aq}) \rightarrow \text{[Ag (P. farcta)]}^+ \quad \text{Equ.1}
\]

\[
\text{[Ag (P. farcta)]}^+ + \text{R-CHO} \rightarrow \text{[Ag (P. farcta)]} + \text{R-COOH} \quad \text{Equ.2}
\]

After dispersion of silver ions in the aqueous fruit extract of *P. farcta* (Equ. 1), the complex of [Ag (P. farcta)]⁺ was reacted with aldehyde groups present in the natural products structure to obtain [Ag (P. farcta)] due to the reduction of silver ions via oxidation of aldehyde to carboxylic acid groups (Equ. 2).

**Optimization study**

**Influence of extract concentration**

The formation process of AgNPs was detected and followed by measuring the surface plasmon resonance (SPR) of *P. farcta* extract and Ag/ *P. farcta* suspensions over the wavelength range of 250 to 700 nm at 50, 60 and 70 °C at 25 and 45 min (Figures 2, 3). SPR bands are affected by the composition, morphology, shape, size and
Figure 2A. UV–vis spectra of different volumes of *P. farcta* fruit extract with aqueous solution of 0.001M AgNO₃ at three different temperatures at 25 min.
Figure 2B. UV–vis spectra of different volumes of *P. farcta* fruit extract with aqueous solution of 0.001M AgNO$_3$ at three different temperatures at 45 min.
dielectric environment of prepared nanoparticles (27, 28). It was proven that spherical silver nanoparticles contribute to the absorption bands around 425–475 nm in the UV–visible spectra (29). UV–visible spectra of nanoparticles were obtained on varying the Prosopis farcta fruit extract volumes at 25 min reaction time. On increasing the volume from 100 µL to 130 µL at 50 °C, $\lambda_{\text{max}}$ was increased from 425 to 438 nm with an increase in the absorbance from 0.721 to 1.111. On further increasing the concentration to 140 µL, a decreasing in $\lambda_{\text{max}}$ to 425 nm with decreasing in the absorbance to 0.647 was observed. Therefore, for further experiments, the volume of 130 µL of Prosopis farcta fruit extract at 25 min was selected. The size of silver nanoparticles depends on the ratio of Ag$^+$ and reducing stabilizing agent. The slight variations in $\lambda_{\text{max}}$ values signify changes in particle size owing to the change in concentration ratios between Prosopis farcta fruit extract and Ag$^+$. Similar evaluation was accomplished at 45 min reaction time. On increasing the volume from 100 µL to 130µL at 50 °C, $\lambda_{\text{max}}$ was increased from 430

to 438 nm with an increase in the absorbance from 0.857 to 1.146. On further increasing the concentration to 140 µL, a small change in λ\text(sub)max\text superscript to 431 nm was observed with decreasing the absorbance to 0.978.

**XRD analysis**

XRD as a powerful nondestructive technique for characterizing crystalline materials provides information on structures, phases, preferred crystal orientations, and other structural parameters, such as average grain size, crystallinity, strain, and crystal defects. XRD pattern clearly exhibited the presence of silver nanoparticles (Figure 4). XRD pattern showed four distinct diffraction peaks at 38, 44, 64.3, and 77.1 which were pertained to (111), (200), (220), and (311) of AgNPs, respectively. All these diffraction peaks can be perfectly indexed to the face-centered cubic (FCC) crystalline structure of Ag, not only in peak position, but also in their relative intensity of the characteristic peaks. The average crystallite size of silver nanoparticles was obtained using Scherrer’s Equation:

![UV–vis spectra of different reaction times of P. farcta fruit extract with aqueous solution of 0.001M AgNO3 at three different temperatures and five different extract volumes at 45 min.](image-url)
In which, $D$ is the crystallite size, $k$ is the shape factor that assumes a value of 0.89 for Ag, $\lambda$ is the X-ray wavelength (1.5406 Å), $\beta$ is the half height width of XRD peak and $\theta$ is the diffraction angle. The diameters of silver nanoparticles were estimated to be at the range 10.26-14.65 nm for all samples.

**TEM analysis**

To investigate the morphology and the particle size of AgNPs, TEM image was taken (Figure 5). A good correlation between the particle size obtained from Scherrer equation and TEM image was observed.

**Total phenolic and flavonoid content**

The results of total phenolic content (TPC) of fruit extract alone or plus AgNPs showed that TPC was higher in plant-AgNPs (462.69 ± 3.42 mg/g GAE) compared to the aqueous fruit extract alone (366.21 ± 3.03 mg/g GAE) (Table 1). The results also revealed that total flavonoids were higher in plant-AgNPs compared to those found in the fruit extract alone (Table 1). Compounds such as phenolics, flavanoids, terpenoids, and soluble proteins have been reported to act as capping agents (30). Similar to our results, Abdel-Aziz et al. (2014) and Sultana et al. (2015) (31, 32) reported a higher total phenol and flavonoid content in synthesized AgNPs compared to the *Chenopodium murale* and *Houttuynia cordata* leaf extract respectively.
TPC was higher in plant- AgNPs (462.69 ± 3.42 mg/g GAE) compared to the aqueous fruit extract alone (366.21 ± 3.03 mg/g GAE) (Table 1). The results also revealed that total flavonoids were higher in plant-AgNPs compared to those found in the fruit extract alone (Table 1). Similar to our results, Abdel-Aziz et al., (2014) and Sultana et al., (2015) (31, 32) reported a higher total phenol and flavonoid content in synthesized AgNPs compared to the Chenopodium murale and Houttuynia cordata leaf extract respectively.

The antioxidant activity of synthesized AgNPs and aqueous fruit extract was determined by using DPPH free radical and FRAP assay. DPPH is a stable compound which can be reduced by accepting the hydrogen or electrons and has been widely used to evaluate the antioxidant activity (33). The lower IC50 value indicates a stronger ability of the extract to act as a DPPH scavenger, while the higher IC50 value indicates a lower scavenging activity. The effect of different concentrations of AgNPs on DPPH radical antioxidant activity is shown in Table 2. Our results revealed that the aqueous fruit extract and synthesized AgNPs are free radical scavengers. However, the AgNPs exhibited more scavenging activity of DPPH than aqueous fruit extract. The DPPH activity of the AgNPs and fruit extract was found to increase in a dose-dependent manner. At concentrations 0.2–1 mg/mL, AgNPs showed a scavenging activity ranging from 43% to 63% with average IC50 value, 0.70 ± 0.08. The antioxidant activity was lower than that of standard ascorbic acid at 1 mg/mL (74%). In FRAP assay, the ability of AgNPs to reduce Fe$^{3+}$ to Fe$^{2+}$ was also significantly higher than that of P. faracta extract at concentrations 0.2–1 mg/mL (Figure 6).

There are few reports on the antioxidant

![Figure 6](image-url)

**Figure 6.** FRAP antioxidant activity of synthesized AgNPs and crude fruit extract of P. farcta. Gentamicin (10μg/mL) was used as a positive control. Each value represents the mean ± standard error of three replicates per treatment.
activity of the biosynthesized AgNPs. AgNPs synthesis, characterization and antioxidant activities, was reported in *Fraxinus excelsior* leaf extract (34), *Terminalia* species leaf extract (35), *Elephantopus caber* (36), *Cleistanthus collinus* [37]. Our result showed that *P. faracta* is a good source of phenolic compounds and flavonoids. Phenolic and flavonoids have been reported to be the most important phytochemicals responsible for the antioxidant capacity (38). In this research the nanoparticles synthesized using fruit extract of *P. faracta* showed antioxidant activity due to capped phenolic compounds. Phenolic group facilitates the conversion of silver nitrate to AgNps due to its electron donating ability (39).

**Antimicrobial activity**

The antibacterial effect of biosynthesized AgNPs (1 & 5 mg/mL) was investigated against various pathogenic organisms such as *S. typhi*, *E. coli*, *S. aureus* and *S. pneumoniae*. AgNPs showed the significant antibacterial activity on all the four bacterial strains tested when compared to the fruit extract (Figure.7). Moreover, AgNPs exhibit effective zone of inhibition against gram-negative bacteria (*S. typhi*, *E. coli*) compared to the gram-positive bacteria (*S. aureus* and *S. pneumoniae*). Among the various tested bacterial the highest zone of inhibition (17.33 ± 0.58 mm) was recorded by *S. typhi* and least zone of inhibition (11 ± 1 mm) was recorded with *S. pneumoniae* (Table 3). Saravanakumar et al., (2015) also reported *Cassia tora* AgNPs had higher bacterial activity against gram-negative bacteria compared to the gram-positive bacteria (40). The potential reason for the antibacterial activity of silver is that AgNPs may attach to the surface of the cell membrane disturbing permeability and respiration functions of the cell. It is also possible that AgNPs not only interact with the surface of the membrane, but can also penetrate inside the bacteria. The higher AgNPs antibacterial activity against gram negative bacteria is due to their thinner peptidoglycan layer which can easily enter in to cell wall to denature or kill bacteria (41).

|                                               | 1                       | 74.49±1.20              |                             |

[Data are presented as mean ± SD (P < 0.05). IC\(_{50}\): Concentration of the aqueous extract and synthesized nanoparticles causing 50% DPPH radical scavenging ability].
A zone of inhibition (17.33 ± 0.58 mm) was recorded by *S. typhi* and least zone of inhibition (11 ± 1 mm) was recorded with *S. pneumoniae*. Saravanakumar et al., (2015) also reported *Cassia tora* AgNPs had higher bacterial activity against gram-negative bacteria compared to the gram-positive bacteria (40). The potential reason for the antibacterial activity of silver is that AgNPs may attach to the surface of the cell membrane disturbing permeability and respiration functions of the cell. It is also possible that AgNPs not only interact with the surface of the membrane, but can also penetrate inside the bacteria. The higher AgNPs antibacterial activity against gram negative bacteria is due to their thinner peptidoglycan layer which can easily enter into cell wall to denature or kill bacteria (41).

Table 3. Antibacterial activity of synthesized AgNPs and fruit extract of *P. farcta* against the human pathogenic bacterial strains.

| Culture                  | Standard     | Fruit extract | AgNPs 1mg | AgNPs 5mg | Fruit extract 5mg |
|--------------------------|--------------|---------------|-----------|-----------|------------------|
| *S. aureus* (Bristol9596) | 14.66±2.51   | -             | 12±1      | 14±2.5    | -                |
| *S. pneumonia* (NCTC7465) | 18.66±2.08   | -             | 11±1      | 13.33±0.58| -                |
| *E. coli* (ATCC25922)    | 28±2.64      | -             | 13.33±3.51| 15±2.65   | -                |
| *S. typhi* (PTCC1609)    | 29.33±3.78   | 7.66±0.57     | 15±1.73   | 17.33±0.58| 8.5±0.5          |

Figure 7. Antibacterial activity of biosynthesized Ag-NPs against human pathogens. Antibacterial effects of biosynthesized Ag-NPs evaluated by the disk diffusion method in petri plates.
Conclusion

The current study revealed that silver nanoparticles can be synthesized in a simple method using *P. farcta* fruit extract. The TEM analysis showed that the sizes of the synthesized AgNPs ranged from 10.26 to 14.65 nm. The total phenolic compounds and total flavonoids were higher in plant-AgNPs compared to the plant extract alone. Plant-AgNPs showed a higher antioxidant and antibacterial activity compared to *P. farcta* fruit extract alone.
