ABSTRACT

Aseptic endocarditis is an uncommon complication of Behçet’s disease (BD). We describe a rare case of a 39-year-old female who had BD with aseptic endocarditis of the tricuspid valve (TV) presenting as tricuspid stenosis. She was diagnosed with BD four years ago. The mucocutaneous lesions were well-controlled with colchicine and short courses of corticosteroids. She remained free of signs and symptoms of BD for one year without any medication. Three months before admission, she gradually developed dyspnea on exertion and peripheral edema. Echocardiography revealed dilated right atrium and markedly thickened TV with severe stenosis. TV replacement was performed. Pathologic examination of the valve showed fibrinoid necrotic material and inflammatory cell infiltration. Blood cultures and cultures of the excised valve were negative for microorganisms. (Korean Circ J 2011;41:399-401)

KEY WORDS: Behçet syndrome; Endocarditis; Tricuspid valve stenosis.

Introduction

Behçet’s disease (BD) is characterized by recurrent aphthous stomatitis, genital ulcers, and various skin lesions. BD can also involve other systems such as ocular, gastrointestinal, articular, neurological and cardiovascular systems. The frequency of cardiovascular involvement is estimated to be 4-46%.[1,2] Common vascular manifestations are thrombophlebitis and arteritis, which occur in as many as one-third of the patients.[3] Aseptic endocarditis is a rare manifestation of BD and is mostly found in the form of intracardiac thrombus or endomyocardial fibrosis.[3,4]

Nonrheumatic tricuspid valve stenosis (TS) is extremely rare, and to our knowledge, it has never been reported in the English literature in patients with BD. We describe a case of a female BD patient with aseptic tricuspid valve (TV) endocarditis presenting as TS.

Case

A 39-year-old female was admitted to Kyungpook National University Hospital with a 3-month history of dyspnea on exertion and abdominal distension. Vital signs were normal and evidence for infectious disease was absent. Signs of right heart failure such as pitting edema, palpable liver and neck vein distension were noted on physical examination. She had been diagnosed with BD four years ago. Although her previous clinical courses fluctuated, she did not show any signs or symptoms of BD since one year before admission. At the time of admission, evidence of BD disease exacerbation was absent; ESR 20 mm/hr (reference 0-20 mm/hr), Ferritin 71.50 ng/mL (reference 13-150 ng/mL).

Transthoracic echocardiography (TTE) showed normal left ventricular function, normal aortic and mitral valve function, morphology, and a moderate to large amount of pericar-
Aseptic Endocarditis in Behçet’s Ds. Presenting as TS
dial effusion. Right atrium was dilated. Pericardiocentesis was
performed. However, precise evaluation of right heart was
difficult on TTE due to poor echo window. Transesophageal
echocardiography showed severe TS with an ill-margined
echogenic mass, and a mild to moderate amount of pericar-
dial effusion (Figs. 1 and 2). Blood cultures for the detection of mi-
croorganisms were negative. Any other possible causes of TS,
such as cardiac tumors, carcinoïd syndrome, marantic endo-
carditis, and Wegener’s granulomatosis were not detected.

Symptoms of right heart failure gradually progressed de-
spite the appropriate steroid and immunosuppressive ther-
apy. She was operated for TS. The thickened TV was remov-
ed and was replaced with an artificial valve (Edwards-MIRA 31
mm). Blood cultures and cultures of the excised valve were ne-
gative for microorganisms. Any other possible causes of TS,
such as cardiac tumors, carcinoïd syndrome, marantic endo-
carditis, and Wegener’s granulomatosis were not detected.

After the TV replacement, she remained free from symp-
toms of right heart failure with immunosuppressive therapy
and anticoagulant therapy.

Discussion

Endocarditis in BD may be limited to the valve leaflets or
may spread to the ventricular or atrial wall and can result in se-
rious complications, such as valvulopathy, organized throm-
bus or endomyocardial fibrosis. However, most cases of en-
docarditis in BD were detected in the form of organized th-
rombus or endomyocardial fibrosis. Not only an intracar-
diac thrombus but also a massive endomyocardial fibrosis
could cause serious functional obstruction of the TV. However,
overt TS due to valvulitis has not been reported, even though
the affected valve leaflets could either be thickened or
replaced by fibrous tissues. Also, we could not find any evi-
dence of other combined sequelae of endocarditis, such as in-
tracardiac thrombosis, endomyocardial fibrosis or valvulopa-
thy of other valves.
McDonald et al.\textsuperscript{10} reported for the first time, a case of endocarditis involving the normal mitral and aortic valves in a patient with BD. These lesions were clinically silent, and were found during autopsy. Histologic examination of these valves showed mononuclear infiltration with a few polymorphonuclear leukocytes and no fibrin deposits. Madanat et al.\textsuperscript{6} reported a case of BD and endocarditis with left atrial thrombosis mimicking myxoma. Postoperative pathologic examination revealed yellowish valvulitis involving the mitral valve leaflet with deep ulcerations on the valve surface, covered by fibrinous and necrotic masses with a significant growth of granulation tissue. In other case reports of endocarditis in BD, several granulomas were found within the central portion of the vegetations and polymorphonuclear cells and lymphocytes infiltrated the small vessels near the vegetations.\textsuperscript{7} In our case, the pathologic examination showed vegetations, consisting of fibrinoid necrotic material, granulation tissue, and inflammatory cells, which were predominantly mononuclear cells. Small arteries and arterioles in the subintimal area showed irregular thickening of the wall. Evidence of active vasculitis was not seen in the excised tissues. These pathologic findings are consistent with those of previous reports. Therefore, TS was caused due to valvulitis as a possible sequelae of endocarditis in BD.

As in this case, the cardiac lesions in BD might progress insidiously in the absence of concurrent signs or symptoms of BD, or they were even diagnosed at autopsy.\textsuperscript{10,11} Therefore, it might be difficult to detect endocarditis in the early stage. These findings suggest that screening for cardiac involvement is required for early detection of endocarditis or other heart diseases in patients with BD.
