A semi-classical approach for solving the time-dependent Schrödinger equation in spatially inhomogeneous electromagnetic pulses

Jianxiong Li and Uwe Thumm
Department of Physics, Kansas State University, Manhattan, Kansas 66506, USA
(Dated: January 24, 2022)

To solve the time-dependent Schrödinger equation in spatially inhomogeneous pulses of electromagnetic radiation, we propose an iterative semi-classical complex trajectory approach. In numerical applications, we validate this method against ab initio numerical solutions by scrutinizing (a) electronic states in combined Coulomb and spatially homogeneous laser fields and (b) streaked photoemission from hydrogen atoms and plasmonic gold nanospheres. In comparison with streaked photoemission calculations performed in strong-field approximation, we demonstrate the improved reconstruction of the spatially inhomogeneous induced plasmonic infrared field near a nanoparticle surface from streaked photoemission spectra.

I. INTRODUCTION

The exposure of gaseous atomic, mesoscopic, and solid targets to incident pulses of electromagnetic radiation of sufficiently high photon energy or intensity leads to the emission of photoelectrons [1]. For more than a century, photoelectron spectroscopy has very successfully exploited this phenomenon and has long become established as one of the most prolific techniques for unraveling the static electronic structure of matter by examining the kinetic-energy or momentum distribution of emitted photoelectrons. More recently, starting in the 21st century, advances in ultrafast laser technology started to extend photoemission spectroscopy into the time domain [2–4]. Importantly, the development of attosecond streaking [5, 6] and interferometric [7, 8] photoelectron spectroscopy enabled the observation of electron dynamics at the natural time scale of the electron motion in matter (attoseconds, 1 as = 10^-18 s). This was demonstrated in proof-of-principle experiments for gaseous atomic [10–13] and molecular [14–16] targets. Attosecond time-resolved photoemission spectroscopy is currently being extended to complex targets [6, 17], such as nanostructures and nanoparticles [21–23], and solid surfaces [19, 24–26], making it possible to examine, for example, the dynamics of photoemission from a surface on an absolute time scale [27] and suggesting, for example, the time-resolved observation of the collective motion of electrons (plasmons) in condensed-matter systems [28–30].

In combination with advances in nanotechnology, allowing the production of plasmonic nanostructures with increasing efficiency at the nm length scale, attosecond photoemission spectroscopy has started to progress towards the spatiotemporal imaging of electron dynamics in complex targets, approaching the atomic length and time scales (nm and attoseconds) [21–23, 28, 31–33]. Photoemission spectroscopy therefore holds promise to become a powerful tool for examining nm-attosecond scale processes that are operative in plasmonically enhanced photocatalysis [33], light harvesting [34], surface-enhanced Raman spectroscopy [35], biomedical and chemical sensing [36], tumor detection and treatment [37], and ultrafast electro-optical switching [38]. The concurrent development and provision of large-scale light sources, capable of producing intense ultrashort pulses in the extreme ultraviolet (XUV) to X-ray spectral range at several leading laboratories in Europe, the United States, and Japan [39], promises to further boost the value of spatiotemporally resolved electron spectroscopy as a tool for imaging electronic dynamics within a wide array of basic and applied research projects.

Being able to take advantage of the full potential offered by current and emerging atomic scale photoelectron imaging techniques relies on theoretical and numerical modeling. This is true for comparatively simple atoms in the gas phase, and for complex nanostructured targets additional theoretical challenges arise [6, 20]. While for atomic photoionization by visible and near UV light, the size of the target is small compared to the wavelength of the incident light pulse, this is no longer true for X-ray ionization, leading to the well-know breakdown of the dipole approximation [50]. Furthermore, for nanoparticles [22–23], (nanostructured) surfaces [30–34], and layered structures [35–39], not only the comparability of the wavelength and structure size requires careful quantum-mechanical modeling beyond the dipole approximation, but also the target’s spatially inhomogeneous dielectric response to the incident light pulse [40–42]. Most numerical models for streaked and interferometric photoemission from atoms are based on the so-called ‘strong-field approximation (SFA)’ [6]. The SFA builds on the assumption that photo-emitted electrons are solely exposed to spatially homogeneous external fields. It discards all other interactions photo-released electrons may be subject to (e.g., with the residual parent ion) and cannot accommodate spatially inhomogeneous final-state interactions.

While the SFA was shown to deteriorate for lower photoelectron energies [43], it completely looses its applicability for complex targets as screening and plasmonic effects expose photoelectrons to inhomogeneous net electromagnetic fields [6, 35–39]. The convenient use of analytically known so-called ‘Volkov wavefunctions’ for the...
photoelectron’s motion in homogeneous electromagnetic fields \[56\] is no longer acceptable, since dielectric response effects entail screening length and induced plasmonic fields at the nm length scale \[28, 29, 30, 36, 38\]. Thus, the numerical modeling of photoemission from complex targets with morphologies or plasmonic response lengths at the nm scale by intense short wavelength pulses (made increasingly available at new (X)FEL light sources \[19\]), necessitates photoemission models beyond the SFA.

To this effect we previously employed heuristically generalized Volkov states to model photoemission from bare and adsorbate-covered metal surfaces \[35, 36, 52, 53\] and plasmonic nanoparticles \[28\]. While this allowed us to numerically model streaked \[32, 52, 53\] and interferometric photoemission spectra from surfaces \[39, 36\], in fair to good agreement with experimental data, and to reconstruct plasmonic fields near gold nanospheres \[28\], a systematic mathematical solution of the time-dependent Schrödinger (TDSE) for a single active electron exposed to inhomogeneous external fields remains to be explored. We here discuss a semiclassical model for obtaining such solutions. While being approximate, our complex-phase Wentzel-Kramer-Brillouin (WKB)-type approach lends itself to systematic iterative refinement. Our proposed method, termed ACCTIVE (Action Calculation by Classical Trajectory Integration in Varying Electromagnetic fields), employs complex classical trajectories to solve the TDSE in the presence of spatially inhomogeneous electromagnetic pulses that are represented by time-dependent inhomogeneous scalar and vector potentials. Our approach is inspired by the semiclassical complex-trajectory method for solving the TDSE with time-independent scalar interactions of Boiron and Lombardi \[58\] and its adaptation to time-dependent scalar interactions by Goldfarb, Schiff, and Tannor \[59\].

Following the mathematical formulation of ACCTIVE in Sec. \[\ref{sec:theory}\] we validate this method by discussing five examples in Sec. \[\ref{sec:examples}\]. We first compare ACCTIVE calculations with \textit{ab initio} numerical solutions by scrutinizing electronic states in (i) homogeneous laser field, (ii) Coulomb field, and (iii) combination of laser and Coulomb fields. Next, we apply ACCTIVE to streaked photoemission from (iv) hydrogen atoms and (v) plasmonic nanoparticles. In the application to Au nanoparticles, we examine final states for the simultaneous interaction of the photoelectron with the spatially inhomogeneous plasmonically enhanced field induced by the streaking infrared (IR) laser pulse and demonstrate the improved reconstruction of the induced nanoplasmonic IR field from streaked photoemission spectra. Section \[\ref{sec:discussion}\] contains our summary. In three appendices we add details of our calculations within ACCTIVE of Volkov wavefunctions (Appendix \[A\]) and Coulomb wavefunctions (Appendix \[B\]), and additional comments on streaked photoemission from Au nanospheres (Appendix \[C\]) within ACCTIVE.

II. THEORY

We seek approximate solutions of the TDSE for a particle of (effective) mass \(m\) and charge \(q\) in an inhomogeneous time-dependent electro-magnetic field given by the scalar and vector potentials \(\phi(\mathbf{r}, t)\) and \(\mathbf{A}(\mathbf{r}, t)\) and an additional scalar potential \(V(\mathbf{r}, t)\),

\[
\frac{i\hbar}{\partial t} \Psi(\mathbf{r}, t) = \left\{ \frac{1}{2m} \left[ -i\hbar \nabla + q\mathbf{A}(\mathbf{r}, t) \right]^2 + \phi(\mathbf{r}, t) \right\} \Psi(\mathbf{r}, t),
\]

where \(\phi(\mathbf{r}, t) = q\phi(\mathbf{r}, t) + V(\mathbf{r}, t)\) and \(V(\mathbf{r}, t)\) is any scalar potential. Representing the wavefunction in eikonal form, \(\Psi(\mathbf{r}, t) = e^{iS(\mathbf{r}, t)/\hbar}\), Eq. \[\ref{eq:tdse}\] can be rewritten in terms of the complex-valued quantum-mechanical action \(S(\mathbf{r}, t)\),

\[
\frac{\partial}{\partial t} S(\mathbf{r}, t) + \frac{1}{2m} \left[ \nabla S(\mathbf{r}, t) - q\mathbf{A}(\mathbf{r}, t) \right]^2 + \phi(\mathbf{r}, t) = \frac{i\hbar}{2m} \mathbf{\nabla} \cdot \left[ \nabla S(\mathbf{r}, t) - q\mathbf{A}(\mathbf{r}, t) \right].
\]

Expanding the action in powers of \(\hbar\) \[58, 59\],

\[
S(\mathbf{r}, t) = \sum_{n=0}^{\infty} \hbar^n S_n(\mathbf{r}, t),
\]

substituting Eq. \[\ref{eq:tdse}\] into Eq. \[\ref{eq:tdse}\], and comparing terms of equal order, results in the set of coupled partial differential equations

\[
\begin{align}
\frac{\partial}{\partial t} S_0(\mathbf{r}, t) + \frac{\left[ \nabla S_0(\mathbf{r}, t) - q\mathbf{A}(\mathbf{r}, t) \right]^2}{2m} + \phi(\mathbf{r}, t) &= 0, \quad (4a) \\
\frac{\partial}{\partial t} S_1(\mathbf{r}, t) + \frac{\left[ \nabla S_0(\mathbf{r}, t) - q\mathbf{A}(\mathbf{r}, t) \right] \cdot \nabla S_1(\mathbf{r}, t)}{m} &= \frac{i}{2m} \mathbf{\nabla} \cdot \left[ \nabla S_0(\mathbf{r}, t) - q\mathbf{A}(\mathbf{r}, t) \right], \quad (4b) \\
\frac{\partial}{\partial t} S_n(\mathbf{r}, t) + \frac{\left[ \nabla S_0(\mathbf{r}, t) - q\mathbf{A}(\mathbf{r}, t) \right] \cdot \nabla S_n(\mathbf{r}, t)}{m} &= -\frac{1}{2m} \sum_{j=1}^{n-1} \nabla S_j(\mathbf{r}, t) \cdot \nabla S_{n-j}(\mathbf{r}, t) + \frac{i}{2m} \nabla^2 S_{n-1}(\mathbf{r}, t) \quad (n \geq 2), \quad (4c)
\end{align}
\]

where the lowest-order contribution \(S_0(\mathbf{r}, t)\) is the classical action of a charged particle moving in the electromagnetic field given by \(\mathbf{E}(\mathbf{r}, t) = -\nabla \phi(\mathbf{r}, t)/q - \partial\mathbf{A}(\mathbf{r}, t)/\partial t\) and \(\mathbf{B}(\mathbf{r}, t) = \nabla \times \mathbf{A}(\mathbf{r}, t)\).

Solving the classical Hamilton-Jacobi equation (HJE) \[\ref{eq:tdse}\] leads to Newton’s Second Law,

\[
\frac{d}{dt} \mathbf{v}(\mathbf{r}, t) = \frac{q}{m} \left[ \mathbf{E}(\mathbf{r}, t) + \mathbf{v}(\mathbf{r}, t) \times \mathbf{B}(\mathbf{r}, t) \right],
\]

where the classical velocity field \(\mathbf{v}(\mathbf{r}, t)\) and kinetic momentum,

\[
\mathbf{p}(\mathbf{r}, t) \equiv m\mathbf{v}(\mathbf{r}, t) \equiv \nabla S_0(\mathbf{r}, t) - q\mathbf{A}(\mathbf{r}, t),
\]
are given in terms of the canonical momentum \( \nabla S_0(r, t) \) \[60\]. The combination of the HJE (4a) and Eq. (6) provides the Lagrangian \( L[r, v(r, t), t] \) as a total time differential of \( S_0(r, t) \),

\[
\frac{d}{dt} S_0(r, t) = L[r, v(r, t), t]
\]

\[
= \frac{1}{2} m v^2(r, t) + q v(r, t) \cdot A(r, t) - \varphi(r, t).
\]  

Similarly, by substituting Eq. (6) into Eqs. (4b) and (9), we find the total time derivatives of the first-order contribution to \( S(r, t) \),

\[
\frac{d}{dt} S_1(r, t) = \frac{i}{2} \nabla \cdot v(r, t),
\]

and of all higher order terms,

\[
\frac{d}{dt} S_n(r, t) = -\frac{1}{2m} \sum_{j=1}^{n-1} \nabla S_j(r, t) \cdot \nabla S_{n-j}(r, t)
\]

\[
+ \frac{i}{2m} \nabla^2 S_{n-1}(r, t) \quad (n \geq 2).
\]  

Approximate solutions to \( S(r, t) \) can be obtained by iteration of Eq. (9), after integrating the total time derivatives in Eqs. (7), (8), and (9) along classical trajectories \( \tilde{r}(t) \) that are defined by

\[
\frac{d}{dt} \tilde{r}(t) \equiv v[\tilde{r}(t), t]
\]

with respect to a reference time (integration constant) \( t_r \). The wavefunction at \( t_r \), \( \Psi(r, t_r) = \Psi(r, t_r) \), provides initial \((t_r \ll 0)\) or asymptotic \((t_r \gg 0)\) conditions in terms of the action

\[
S(r, t_r) = -i \hbar \ln[\Psi(r)]
\]  

and the velocity field

\[
v(r, t_r) = -\frac{1}{m} \nabla S_0(r, t_r) - \frac{q}{m} A(r, t_r)
\]

\[
\approx -\frac{1}{m} \nabla S(r, t_r) - \frac{q}{m} A(r, t_r)
\]

\[
= -\frac{i \hbar \nabla \Psi(r)}{m \Psi(r)} - \frac{q}{m} A(r, t_r).
\]  

The semiclassical solution of Eqs. (7), (8), and (9) requires an appropriate classical trajectory \( \tilde{r}(t') \) - for any given ‘current’ event \((r, t)\) - that connects the ‘current’ coordinate and velocity,

\[
r = \tilde{r}(t), \quad v = \left. \frac{d\tilde{r}(t')}{dt'} \right|_t
\]

\[
r_r = \tilde{r}(t_r),
\]

\[
v_r = \left. \frac{d\tilde{r}(t')}{dt'} \right|_{t_r} = -\frac{i \hbar \nabla \Psi(r)}{m \Psi(r)} - \frac{q}{m} A(r, t_r).
\]

The known quantities in Eqs. (13) and (14) are \( r, t, t_r, v_r \), \( r_r \), and \( v_r \), while \( v_r \), \( r_r \), and \( v_r \) are to be determined. To numerically calculate the undetermined quantities, we employ a shooting method, starting with a ‘trial’ velocity \( v_{\text{trial}} \) at position \( r \) and time \( t_r \). Propagating \( r \) to the reference time according to Eq. (3) results in \( r_{\text{trial}} = r_{\text{trial}}(t_r) \) and \( v_{\text{trial}} = v_{\text{trial}}(t_r) \) \( dt' \mid_{t_r} \).

The velocity field \( v \) that satisfies Eq. (5) can now be found numerically by minimizing the function

\[
f(v_{\text{trial}}) = |v_{r_{\text{trial}}} - i\hbar \nabla \Psi(r_{\text{trial}})| + \frac{q}{m} A(r_{\text{trial}}, t_r) |
\]  

for an appropriate range of start trial velocities. In our numerical applications this is accomplished by an efficient multi-dimensional quasi-Newton root-finding algorithm (Broyden’s method) \[61\] \[62\]. Once the correct trajectories \( \tilde{r}(t') \) are determined by finding the roots of Eq. (15), the actions in Eqs. (7), (8), and (9) are integrated along these trajectories and composed - by truncating Eq. (3) - into an approximate solution of Eq. (1).

Since each term \( S_n(r, t) \) in Eq. (3) depends only on lower orders, ACCTIVE enables, in principle, the systematic iterative refinement of approximate solutions of Eq. (1) by including successively higher orders \( n \).

The iteration is started with \( S_0(r, t) \), which is determined by the velocity field \( v(r, t) \), and continued by integrating Eqs. (5) and (6).

In the numerical examples discussed in Sec. \[11\] below, we find that retaining only the zero’th and first-order terms, \( S_0(r, t) \) and \( S_1(r, t) \), provides sufficiently accurate and physically meaningful solutions at modest numerical
expense. Thus, according to Eqs. (7) and (8), we apply
\[ \Psi(r, t) \approx \exp \left\{ iS_0(r, t)/\hbar + iS_1(r, t) \right\} \]
\[ = e^{iS(r, t_\tau)/\hbar} \exp \left\{ - \frac{1}{2} \int_{t_\tau}^{t} \nabla \cdot V(r(t'), t') dt' \right\} + \frac{i}{\hbar} \int_{t_\tau}^{t} \left[ \bar{r}(t'), \mathbf{v}(\bar{r}(t'), t'), t' \right] dt'. \]  
(16)

For real classical trajectories and potentials, the integral of \( S_0(r, t) \) is real, representing a local phase factor, while \( S_1(r, t) \) is purely imaginary and defines the wavefunction amplitude, as in the standard WKB approach. The quantum-mechanical probability density \( \rho(r, t) \) then satisfies the continuity equation,
\[ \frac{d\rho(r, t)}{dt} = \frac{d}{dt} \left| \Psi(r, t) \right|^2 = -\rho(r, t)\nabla \cdot \mathbf{v}(r, t), \]  
(17)
for the classical probability flux \( \rho(r, t)\mathbf{v}(r, t) \) [63].

### III. EXAMPLES

We validate the ACCTIVE method by discussing five applications to electron wavefunctions in Coulomb and laser fields.

#### A. Volkov wavefunction

For the simple example of an electron in a time-dependent, spatially homogeneous laser field, the potentials in Eq. (1) and reference wavefunction are (in the Coulomb electromagnetic gauge) [50]
\[ \mathbf{A}(r, t) = \mathbf{A}(t), \quad \varphi(r, t) = 0, \quad \Psi_r(r) = e^{i\mathbf{p} \cdot \mathbf{r} / \hbar}, \]  
(18)
and the first-order wavefunction in Eq. (16) reproduces the well-known analytical Volkov solution [50],
\[ \Psi^V(r, t) = \exp \left\{ i \frac{\mathbf{p} \cdot \mathbf{r}}{\hbar} - \frac{i}{2m\hbar} \int_{t_\tau}^{t} \left[ \mathbf{p} - q \mathbf{A}(t') \right]^2 dt' \right\}. \]  
(19)
For details of the derivation of Eq. (19) within ACCTIVE see Appendix A.

#### B. Coulomb wavefunction

As a second simple example and limiting case, we consider an unbound electron in the Coulomb field of a proton. In this case the potentials in Eq. (1) are
\[ \mathbf{A}(r, t) = 0, \quad \varphi(r, t) = -k_c e^2 / r, \]  
(20)
where \( e \) is the elementary charge and \( k_c \) the electrostatic constant. Assuming outgoing-wave boundary conditions, we define the reference wavefunction at a sufficiently large reference time \( t_r \) as the ‘outgoing’ Coulomb wave
\[ \Psi_r(r, t_r) \xrightarrow{t_r \to \infty, z \to \pm \infty} e^{ikz - \hbar k^2 / 2m} \delta(\mathbf{r}). \]  
(21)

Here \( r = (x, y, z) \) and \( p = \hbar \mathbf{k} > 0 \) is the final electron momentum. In this case the TDSE is solved exactly by the well-known Coulomb wavefunction
\[ \Psi^C_r(r, t) = \frac{e^{\pi i \Gamma(1-i/k)}}{(2\pi)^{3/2}} \Gamma_{1F1}(i/k, 1, ikr - ikz) e^{ikz - \hbar k^2 / 2m} \]  
(22)
in terms of the confluent hypergeometric function \( 1F1 \). Note that for finite distances from the z-axis (i.e., for finite coordinates \( x \) and \( y \)), the asymptotic form of the Coulomb continuum wavefunction for \( z \to +\infty \) is just a plane wave (without a logarithmic phase term) [50, 51].

Applying ACCTIVE to the outgoing-wave Coulomb problem, \( t_r \) must be chosen sufficiently long after \( t \), so that each classical trajectory \( \bar{r}(t') \) propagates far enough towards the \( z \to +\infty \) asymptotic limit for the reference velocity to become
\[ \mathbf{v}_r \xrightarrow{t_r \to \infty, z \to \pm \infty} \dot{\mathbf{p}} / m, \]  
(23)
in compliance with Eq. (14b). In this and for the following numerical example, we use as reference velocity the initial trial velocity for points of the spatial numerical grid that are sufficiently far away from the Coulomb singularity at the origin. The correct ‘current’ velocities, \( \mathbf{v}(r, t) \) at the most distant coordinates are subsequently used as trial velocities at the nearest neighbor spatial grid points. This scheme is continued until classical trajectories for the entire spatiotemporal numerical grid are calculated. Further details of the numerical calculation of Coulomb wavefunctions within ACCTIVE are given in Appendix B.

Figure 2 shows the very good agreement between the numerically calculated 1st order ACCTIVE wavefunction (16) and the analytical Coulomb wavefunction (22).
for a final electron kinetic energy of \( p^2/2m = 50 \) eV. The color/gray scale represents the real part of the wavefunction in the \( x-z \) plane. Figures 2(a) and 2(b) show the same scattering pattern. Good quantitative agreement of the 1st order ACCTIVE wavefunction and the analytical Coulomb wavefunction is demonstrated in Fig. 2(c).

C. Coulomb-Volkov wavefunction

A more challenging third example is given by the motion of an electron under the combined influence of a point charge (proton), located at the coordinate origin, and a spatially homogeneous laser pulse, subject to the boundary condition Eq. (21). In this case, the potentials in Eq. (1) are (in Coulomb gauge [50])

\[
A(r, t) = A(t), \quad \varphi(r, t) = -\frac{e^2}{r}. \tag{24}
\]

Considering a laser pulse of finite duration, \( t_r \) must be chosen such that the laser electric field vanishes at \( t_r \). This combination of the two previous examples in Secs. IIIA and IIIB constitutes the Coulomb-Volkov problem, for which merely approximate solutions [65-68], but no analytical wavefunction are known. We assume a laser pulse with 15 eV central photon energy, a cosine-square temporal intensity envelope with a pulse length of 0.5 fs full width at half intensity maximum (FWHM), and \( 3 \times 10^{15} \) W/cm² peak intensity. At time \( t = 0 \), the temporal pulse profile is centered at \( z = 0 \). We enforce the outgoing-wave boundary condition for an asymptotic photoelectron kinetic energy of \( p^2/2m = 50 \) eV. This energy is reached at a sufficiently large distance of the outgoing electron from the proton and long after the pulse has vanished.

In Fig. 3 we compare the ACCTIVE-calculated Coulomb-Volkov wavefunction with Coulomb and Volkov wavefunctions for identical outgoing-wave boundary condition and 50 eV asymptotic photoelectron kinetic energy. The Coulomb and Volkov wavefunctions are given for a positive elementary charge and the same laser parameters as the Coulomb-Volkov wave, respectively. The color/gray scale represents the real part of the wavefunctions. We determined all numerical parameters (numerical grid size, spacing and propagation time step) to ensure convergence of the wavefunctions.

Figures 3(a), 3(b), and 3(c), display snapshots at time \( t = 0 \) of the Coulomb, ACCTIVE-calculated Coulomb-Volkov, and Volkov wavefunctions, respectively. The Coulomb-Volkov wavefunction shows a similar (inverse) Coulomb scattering pattern for the incident wave (\( z < 0 \)) as the Coulomb wave. Its outgoing part (\( z > 0 \)) closely matches the phase of the Volkov wave. On the other hand, the time-dependent evolution of the Coulomb-Volkov wavefunction in the \( y = 0 \) plane in Fig. 3(e) shows laser-induced wavefront distortions - similar to the Volkov wave in Fig. 3(f). The time evolution of the ACCTIVE-calculated Coulomb-Volkov wavefunction reveals the acceleration of the incoming and deceleration of the outgoing wave near the proton at \( z = 0 \) of the pure Coulomb wave in Fig. 3(d).

D. Streaked photoemission from hydrogen atoms

As a fourth example, we employ ACCTIVE final-state wavefunctions to calculate IR-streaked XUV photoelectron spectra from ground-state hydrogen atoms [4]. We assume the ionizing XUV and streaking IR pulse as linearly polarized along the \( z \) axis. The relative time delay between the centers of the two pulses, \( \tau \), is assumed positive in case the IR precedes XUV pulse. The electric field \( E_X(t) \) of the XUV pulse is characterized by a Gaussian temporal profile, 55 eV central photon energy, and a pulse length of 200 as (FWHM). The IR pulse has a cosine-squared temporal profile, 720 nm central wavelength, pulse duration of 2 fs FWHM, and \( 10^{11} \) W/cm² peak intensity.

We model streaked photoemission from the ground state of hydrogen, \( |\Psi_i\rangle \), based on the quantum-mechanical transition amplitude [3]

\[
T(k_f, \tau) \sim \int dt \, \langle \Psi_{k_f, \tau}^{\text{C-V}} | z E_X(t) | \Psi_i \rangle, \tag{25}
\]

where the IR-pulse-dressed final state of the photoelectron, \( |\Psi_{k_f, \tau}^{\text{C-V}}\rangle \), is a Coulomb-Volkov wavefunction [54] that we evaluate numerically using the ACCTIVE method. In a comparison calculation, we replace the
Coulomb-Volkov state by the Volkov state $|\psi_{k,r,\tau}\rangle$ and assume otherwise identical physical conditions. As mentioned in the Introduction, the use of Volkov states in photoionization calculations is referred to as SFA \cite{5} and amounts to neglecting the interaction of the released photoelectron with the residual ion (proton in the present case). We scrutinize streaked photoemission spectra obtained with ACCTIVE-calculated Coulomb-Volkov final states and in SFA against \textit{ab initio} bench-mark calculations. In these exact numerical calculations we directly solve the three-dimensional TDSE using the SCID-TDSE time-propagation code \cite{70}.

Numerical results are shown in Fig. 4. The streaked photoemission spectra obtained with ACCTIVE-calculated Coulomb-Volkov final states [Fig. 4(a)], in SFA [Fig. 4(b)], and by direct numerical solution of the TDSE [Fig. 4(c)] show very similar ‘streaking traces’, i.e., oscillations of the asymptotic photoelectron energy with delay $\tau$. For a quantitative comparison, we plot in Fig. 4(d) the centers of energy (CoEs) of the spectra in Figs. 4(a-c). While the three calculations result in identical photoemission phase shifts (streaking time delays) relative to the streaking IR field, within the resolution of the graph, the ACCTIVE-calculated spectra agree with the exact TDSE calculation, while the SFA calculation predicts noticeably smaller CoEs due to the neglect of the Coulomb potential in the final photoelectron state \cite{22}.

E. Streaked photoemission from metal nanospheres

As a final, fifth, example, we apply the ACCTIVE method to model photoelectron states in \textit{spatially inhomogeneous}, plasmonically enhanced IR electromagnetic fields. For this purpose, we investigate streaked photoemission \cite{22,23,27} and the reconstruction of plasmonic near-fields \cite{28} for gold nanospheres with a radius of $R = 50$ nm. We represent the electronic structure of the nanosphere in terms of eigenstates of a square well with a potential depth of $V_0 = -13.1$ eV and obtain the photoelectron yield by incoherently adding the transition amplitudes \cite{25} over all occupied initial conduction-band states \cite{6,53,57}. For the calculation of the transition amplitude \cite{25} we closely follow Ref. \cite{26}, with the important difference of employing numerically calculated semiclassically ACCTIVE final photoelectron wavefunctions, while in Ref. \cite{26} the SFA approximation is used, applying heuristicaly generalized Volkov final states and thus neglecting of the photoelectron interactions with the residual nanoparticle.

For the ACCTIVE calculation we thus solve the TDSE \cite{1} with the potentials

\begin{equation}
A(r,t) = \int_{t}^{\infty} E_{\text{tot}}(r,t') \, dt', \quad (26a)
\end{equation}

\begin{equation}
\varphi(r,t) = \begin{cases} V_0 & r < R \\ 0 & r \geq R \end{cases}, \quad (26b)
\end{equation}

and the boundary condition Eq. (21). Here, the asymptotic wavefunction in Eq. (21) also serves as reference wavefunction for the classical trajectory computation. The net time-dependent inhomogeneous field $E_{\text{tot}}(r,t)$ is given by the superposition of the homogeneous IR field of the incident streaking pulse and the inhomogeneous plasmonic field produced by the nanoparticle in response to the incident IR pulse \cite{27,28}. For the streaking calculation, we assume an XUV pulse with 30 eV central photon energy and Gaussian temporal profile with a width of 200 as (FWHIM). We further suppose a delayed Gaussian IR pulse with 720 nm central wavelength, 2.47 fs (FWHIM) pulse length, and $5 \times 10^{10}$ W/cm$^2$ peak intensity.

Figure 5 shows simulated streaked photoelectron spectra obtained with ACCTIVE-calculated and Volkov final states for electron emission along the XUV-pulse polarization direction. In this direction, the effect of the induced plasmonic field on the photoelectron is strongest \cite{28}. The corresponding spectra in Figs. 5(a) and 5(b) show very similar temporal oscillations of the photoelectron yield and CoE as a function of both, asymptotic photoelectron energy and XUV-IR pulse delay $\tau$. As for streaked photoemission from hydrogen atoms discussed in Sec. III D above, we find that the SFA shifts the CoE to lower kinetic energies [Fig. 5(b), cf.
IV. SUMMARY

In summary, we propose a semi-classical method, ACCTIVE, to solve the TDSE for one active electron exposed to any spatially inhomogeneous time-dependent external force field. We validate this method by comparing ACCTIVE-calculated electronic wavefunctions with known Coulomb and Volkov wavefunctions for the electronic dynamics in Coulomb and intense laser fields, respectively, and by scrutinizing ACCTIVE-calculated Coulomb-Volkov final photoelectron wavefunctions (i) against \textit{ab initio} numerical solutions of the TDSE and (ii) in streaked photoemission from hydrogen atoms and plasmonic metal nanospheres.

For streaked photoemission from hydrogen atoms, we demonstrate excellent agreement of our ACCTIVE calculation with a benchmark \textit{ab initio} TDSE calculation, while a comparative calculation using the SFA systematically deviates from the exact TDSE solution. For streaked photoemission from Au nanospheres we find that ACCTIVE final-state wavefunctions improve the reconstruction of plasmonic near-fields over SFA calculations (based on Volkov final states) at comparatively low photoelectron energies.

Appendix A: Derivation of Eq. (19)

We here derive the Volkov wavefunction Eq. (19) using ACCTIVE. Starting from the potentials and initial wavefunction in Eq. (18), the velocity field along the classical trajectory \( \mathbf{\tilde{r}}(t) \) is

\[
\mathbf{v}(\mathbf{r},t) = \frac{\mathbf{p}}{m} + \frac{q}{m} \int_{t_0}^{t} \mathbf{E}(t')dt' = \frac{\mathbf{p} - q \mathbf{A}(t)}{m}. \tag{A1}
\]

Therefore,

\[
\mathbf{\tilde{r}}(t) = \mathbf{r}_0 + \int_{t_0}^{t} \left[ \frac{\mathbf{p} - q \mathbf{A}(t)}{m} \right] dt', \tag{A2}
\]

\( \mathbf{r}_0 \) being the initial position and \( \mathbf{A}(t) \) the external force field. We validate this method by comparing ACCTIVE-calculated electronic wavefunctions with known Coulomb and Volkov wavefunctions for the electronic dynamics in Coulomb and intense laser fields, respectively, and by scrutinizing ACCTIVE-calculated Coulomb-Volkov final photoelectron wavefunctions (i) against \textit{ab initio} numerical solutions of the TDSE and (ii) in streaked photoemission from hydrogen atoms and plasmonic metal nanospheres.

For streaked photoemission from hydrogen atoms, we demonstrate excellent agreement of our ACCTIVE calculation with a benchmark \textit{ab initio} TDSE calculation, while a comparative calculation using the SFA systematically deviates from the exact TDSE solution. For streaked photoemission from Au nanospheres we find that ACCTIVE final-state wavefunctions improve the reconstruction of plasmonic near-fields over SFA calculations (based on Volkov final states) at comparatively low photoelectron energies.

Fig. 4(d)]. Here, the SFA results in an approximately 1.5 eV lower CoE than the ACCTIVE calculation. This energy shift is due to the fact that the SFA, by neglecting the potential well of the nanosphere in the final photoelectron state, leads to an unphysical enhancement of the photoemission cross section at lower photoelectron kinetic energies, thereby increasing the weight of low energy yields in the CoE average [22].

Addition comments on the comparison of streaked photoelectron spectra within either ACCTIVE or based on Volkov wavefunctions can be found in Appendix [C].

From streaked photoemission spectra the plasmonic near-field at the nanoparticle surface can be reconstructed as detailed in Refs. [27, 28]. Figure 5(d) shows the reconstructed net electric field \( \mathbf{E}_{\text{net}} \) along the XUV-pulse polarization direction, i.e., at the surface and on the positive z axis, of the nanosphere. The reconstruction of net plasmonically enhanced near-fields from the simulated spectra in Figs. 5(a) and 5(b) was performed according to the scheme proposed in Ref. [28]. The obtained reconstructed fields are compared in Fig. 5(d) with the net electric IR near-field obtained within Mie theory [71] and used as input in the streaking calculations. As is seen in Fig. 5(d), the ACCTIVE method improves the near-field reconstruction in comparison with the SFA calculation. The least-square deviation between the reconstructed and Mie-theory calculated fields, assembled over the entire IR pulse length, amounts to 1.62% using the ACCTIVE wavefunction and 3.05% using the SFA. A comparative animation of reconstructed and analytical electric fields at the surface of Au nanospheres can be found in the Supplemental Material [69]. The ACCTIVE method thus extends the applicability of the plasmonic near-field reconstruction scheme in Ref. [28] to lower XUV photon energies.

IV. SUMMARY

In summary, we propose a semi-classical method, ACCTIVE, to solve the TDSE for one active electron exposed to any spatially inhomogeneous time-dependent external force field. We validate this method by comparing ACCTIVE-calculated electronic wavefunctions with known Coulomb and Volkov wavefunctions for the electronic dynamics in Coulomb and intense laser fields, respectively, and by scrutinizing ACCTIVE-calculated Coulomb-Volkov final photoelectron wavefunctions (i) against \textit{ab initio} numerical solutions of the TDSE and (ii) in streaked photoemission from hydrogen atoms and plasmonic metal nanospheres.

For streaked photoemission from hydrogen atoms, we demonstrate excellent agreement of our ACCTIVE calculation with a benchmark \textit{ab initio} TDSE calculation, while a comparative calculation using the SFA systematically deviates from the exact TDSE solution. For streaked photoemission from Au nanospheres we find that ACCTIVE final-state wavefunctions improve the reconstruction of plasmonic near-fields over SFA calculations (based on Volkov final states) at comparatively low photoelectron energies.

Appendix A: Derivation of Eq. (19)

We here derive the Volkov wavefunction Eq. (19) using ACCTIVE. Starting from the potentials and initial wavefunction in Eq. (18), the velocity field along the classical trajectory \( \mathbf{\tilde{r}}(t) \) is

\[
\mathbf{v}(\mathbf{r},t) = \frac{\mathbf{p}}{m} + \frac{q}{m} \int_{t_0}^{t} \mathbf{E}(t')dt' = \frac{\mathbf{p} - q \mathbf{A}(t)}{m}. \tag{A1}
\]

Therefore,

\[
\mathbf{\tilde{r}}(t) = \mathbf{r}_0 + \int_{t_0}^{t} \left[ \frac{\mathbf{p} - q \mathbf{A}(t)}{m} \right] dt'. \tag{A2}
\]

\( \mathbf{r}_0 \) being the initial position and \( \mathbf{A}(t) \) the external force field. We validate this method by comparing ACCTIVE-calculated electronic wavefunctions with known Coulomb and Volkov wavefunctions for the electronic dynamics in Coulomb and intense laser fields, respectively, and by scrutinizing ACCTIVE-calculated Coulomb-Volkov final photoelectron wavefunctions (i) against \textit{ab initio} numerical solutions of the TDSE and (ii) in streaked photoemission from hydrogen atoms and plasmonic metal nanospheres.

For streaked photoemission from hydrogen atoms, we demonstrate excellent agreement of our ACCTIVE calculation with a benchmark \textit{ab initio} TDSE calculation, while a comparative calculation using the SFA systematically deviates from the exact TDSE solution. For streaked photoemission from Au nanospheres we find that ACCTIVE final-state wavefunctions improve the reconstruction of plasmonic near-fields over SFA calculations (based on Volkov final states) at comparatively low photoelectron energies.

Appendix A: Derivation of Eq. (19)

We here derive the Volkov wavefunction Eq. (19) using ACCTIVE. Starting from the potentials and initial wavefunction in Eq. (18), the velocity field along the classical trajectory \( \mathbf{\tilde{r}}(t) \) is

\[
\mathbf{v}(\mathbf{r},t) = \frac{\mathbf{p}}{m} + \frac{q}{m} \int_{t_0}^{t} \mathbf{E}(t')dt' = \frac{\mathbf{p} - q \mathbf{A}(t)}{m}. \tag{A1}
\]

Therefore,

\[
\mathbf{\tilde{r}}(t) = \mathbf{r}_0 + \int_{t_0}^{t} \left[ \frac{\mathbf{p} - q \mathbf{A}(t)}{m} \right] dt', \tag{A2}
\]
\[ \nabla \cdot \mathbf{v}(r, t) = 0, \quad (A3) \]

and Eq. (16), applied to the example in Sec. IIIA, becomes

\[
\Psi(r, t) = \exp \left\{ \frac{i\mathbf{p} \cdot \mathbf{r}}{\hbar} + \frac{i}{\hbar} \int_{t_0}^{t} \left[ \frac{m}{2} \left( \frac{\mathbf{p} - q\mathbf{A}(t')}{m} \right)^2 \right. \right. \\
+ q \left( \frac{\mathbf{p} - q\mathbf{A}(t')}{m} \cdot \mathbf{A}(t') \right] dt' \left. \right\} \\
= \exp \left\{ \frac{i\mathbf{p} \cdot \mathbf{r}}{\hbar} - \int_{t_0}^{t} \left[ \frac{m}{2} \left( \frac{\mathbf{p} - q\mathbf{A}(t')}{m} \right)^2 \right. \right. \\
- m \left( \frac{\mathbf{p} - q\mathbf{A}(t')}{m} \right)^2 dt' \left. \right\} \\
= \exp \left\{ \frac{i \mathbf{p} \cdot \mathbf{r}}{\hbar} - \frac{i}{2m\hbar} \int_{t_0}^{t} \left[ \mathbf{p} - q\mathbf{A}(t') \right]^2 dt' \right\}, \quad (A4) \]

which is the Volkov wavefunction Eq. (19).

**Appendix B: Numerical calculation of Coulomb wavefunctions using ACCTIVE**

The ACCTIVE method links a quantum-mechanical problem of obtaining wavefunctions \( \Psi(r, t) \) to a classical problem of determining velocity fields \( \mathbf{v}(r, t) \). However, in some cases, e.g., for Coulomb wavefunctions, such velocity fields are not uniquely defined (Fig. 6). This can result in interference patterns in the obtained wavefunctions, as pointed out by Goldfarb et al. [59].

For each event \((r, t)\), two possible classical trajectories can be found to satisfy the same boundary condition of an outgoing plane wave in Eq. (21), as shown in Fig. 6. Goldfarb et al. [59] take this interference into account by approximating the wavefunction as the superposition of contributions from different trajectories,

\[
\Psi(r, t) \approx \sum_{l} \exp \left\{ \frac{i}{\hbar} S_l(r(t), t) \right\}, \quad (B1) \]

where each action \( S_l(r, t) \) is associated with a trajectory \( r(t) \). In this work, we follow a different and simpler approach.

The TDSE is a linear partial differential equation. Its solution can be expressed as the superposition of a set of linearly independent basis functions \( \Psi^l(r, t) \),

\[
\Psi(r, t) = \sum_{l} C_l \Psi^l(r, t) = \sum_{l} C_l \exp \left\{ \frac{i}{\hbar} S^l(r, t) \right\}, \quad (B2) \]

where each \( S^l(r, t) \) is uniquely determined by a velocity field \( \mathbf{v}^l(r, t) \) and the coefficients \( C_l \) are obtained from the initial condition,

\[
\Psi_0(r) = \sum_{l} C_l \Psi^l(r, t_0). \quad (B3) \]

Since two possible trajectories can be obtained for each given event \((r, t)\), we can find two velocity fields, \( \mathbf{v}^+(r, t) \) and \( \mathbf{v}^-(r, t) \), which are defined by

\[
\mathbf{v}^+(r, t) \xrightarrow{z \to \pm \infty, x > 0} \mathbf{p}/m \quad (B4a) \\
\mathbf{v}^-(r, t) \xrightarrow{z \to \pm \infty, x < 0} \mathbf{p}/m \quad (B4b) \]

as illustrated in Fig. 7(a) and 7(b), respectively. Figures 7(c) and 7(d) show the calculated 1st-order ACCTIVE wavefunctions, \( \Psi^+(r, t) \) and \( \Psi^-(r, t) \), associated with these two velocity fields at \( t = 0 \). Numerical calculation shows that,

\[
\Psi^+(r, t) \xrightarrow{z \to \pm \infty} \begin{cases} 
e \mathbf{p}/m \\ 0 \end{cases} \quad (B5a) \\
\Psi^-(r, t) \xrightarrow{z \to \pm \infty} \begin{cases} \mathbf{p}/m \\ 0 \end{cases}. \quad (B5b) \]

Therefore, at \( t_0 \), \( \Psi_0(r) = \Psi(r, 0) \) can be written as the linear combination of \( \Psi^+(r, t_0) \) and \( \Psi^-(r, t_0) \) and satisfies the boundary condition (B4),

\[
\Psi_0(r) = \Psi^+(r, t_0) + \Psi^-(r, t_0). \quad (B6) \]
The wavefunction at any given time \( t \) is then obtained with the same coefficients,

\[
\Psi(r, t) = \Psi^+(r, t) + \Psi^-(r, t),
\]

as shown in Fig. 7(e).

**Appendix C: Comments on streaked photoemission from Au nanospheres**

Figure 5 in the main text shows the comparison of simulated streaked photoelectron spectra using either ACCTIVE wavefunctions as final states or Volkov wavefunction in SFA. ACCTIVE wavefunctions are more accurate at low photoelectron energy, but entail higher CoEs than Volkov wavefunctions [Fig. 5(c)]. In comparison with Fig. 4(d), this might appear as counter-intuitive. An explanation is given below.

Figure 8(a) shows the real part of the 1st-order ACCTIVE wavefunction near the Au nanosphere surface, and Fig. 8(b) the corresponding Volkov wavefunction in SFA [28]. Both are calculated for photoelectron detection along the XUV polarization direction and outgoing photoelectron energy \( E_f = 5 \) eV. Inside the nanosphere, the Volkov final-state wavefunction neglects the spherical well potential. It therefore has a longer wavelength than the ACCTIVE wavefunction and more strongly overlaps with the initial-state wavefunction shown in Fig. 8(c). Thus, the cross section, calculated following Ref. [50], is larger in SFA than if based on ACCTIVE final states.

This effect becomes less significant at larger photoelectron kinetic energies, where both, ACCTIVE and SFA wavefunctions have shorter wavelengths and overlap less with initial-state wavefunction. Figure 8(d) shows that the energy-dependent photoemission cross sections calculated with ACCTIVE and Volkov final states converge at large photoelectron energies, while at small energies the SFA leads to larger cross sections. The net effect of this cross-section difference is to put more weight on photoelectron yields at lower energy and thus to shift streaking traces and CoEs in SFA photoemission spectra to lower energies as compared to ACCTIVE-calculated spectra.
