BASAVESHWARA MEDICAL COLLEGE AND HOSPITAL, CHITRADURGA, INDIA

Background. The amount of evidence regarding the relation between serum lipids, lipoproteins and cerebrovascular accident is not adequate. The atherogenecity of diabetics and non-diabetics are different. Therefore, non-diabetic patients were included in the study.

Objective. To study lipid abnormalities in non-diabetic stroke patients in our setup.

Methods. The study was carried out at the Department of General Medicine, BMCH, Chitradurga, during the period from June 2020 to December 2020. The lipid profile and the fasting blood sugar rates of 50 stroke patients without diabetes were studied. Their serum samples were assessed for fasting blood glucose (FBG), total cholesterol (TC), triglycerides (TG), low density lipoprotein cholesterol (LDL) and high-density lipoprotein cholesterol (HDL) by using standard biochemical methods.

Results. The age distribution of the subjects was from 19 to 72 years with a mean age of patients 54.8±15.75 years. Among patients 31 (62%) were males and 19 (38%) were females. Among the study subjects 58% were hypertensive, 76% were smokers, 32% were alcoholics and 34% had family history of cerebrovascular accident. Among ischemic stroke group, the most common deranged value in the ischemic group was decreased HDL deranged in 54.1% of patients; the second most common deranged value – increased VLDL deranged in 40.5%. Among the hemorrhagic group the most common deranged value was also decreased HDL which was deranged in 46.1% of patients and the second most common deranged value – increased total cholesterol, which was deranged in 53.8% patients.

Conclusion. Lipid profile should be considered while predicting the risk of stroke.

KEYWORDS: lipid profile; dyslipidemia; non-diabetic stroke; serum cholesterol.

Introduction
As per World Health Organization, stroke is defined as a clinical syndrome consisting of rapidly developing clinical signs of focal (at times global) disturbance of cerebral function, with duration lasting more than 24 hours or leading to death with no apparent cause other than that of vascular origin [1].

Stroke is the second leading cause of death worldwide causing 6.2 million deaths in 2011 [2]. Stroke is a medical emergency which is an acute neurological injury that occurs due to vascular pathology and presents as a brain infarction or haemorrhage. The modification of risk factors in stroke has brought down both mortality and morbidity of stroke remarkably in the last 30 years. Dyslipidemia is a major risk factor for stroke. It has been established that reduction of total cholesterol, LDL cholesterol, triglycerides, VLDL cholesterol and increasing HDL cholesterol by drugs decreases the incidence of stroke.

In our study, lipid profile was studied in non-diabetic patients with stroke. Diabetes itself is associated with hyperlipidemia and increased atherosclerosis which makes it an undisputed risk factor for stroke. The atherogenecity of diabetics and non-diabetics are different. With this background, we conducted the study of lipid profile in the non-diabetics with stroke in our setup.

Methods
Patients with stroke and non-diabetic attending OPD and IPD of the Department of General Medicine of Basaveshwara Medical College and Hospital, Chitradurga, were enrolled in the study. Patients with haemorrhagic strokes, embolic strokes, past/present H/O diabetes mellitus or history of head injury or usage of anti-coagulant drugs were excluded from the study.

The study took place over the period of 6 months from June 2020 to December 2020.
Sample size estimation was performed using open epi software version 2.3.1 at 95% confidence level, 80% power of the study, proportion of cases with stroke with raised lipid parameters as 70% [3]. Sample size estimated was 37 inflated to 50.

A brief personal history and medical history, including brief histories about co-existing disease states, family history of diabetes mellitus, and history of hypertension, past and present illnesses, dietary pattern, addiction and medication were recorded in self prepared questionnaire. Detailed general physical examination, systemic examination and neurological examination were performed to all the patients and were recorded.

The investigations done for the patients at presentation included fasting lipid profile (serum total cholesterol, serum triglycerides, serum high density lipoproteins, serum very low density lipoproteins, serum low density lipoproteins) and HbA1c levels [4].

Data was entered in excel sheet and analysed using the Statistical Package for the Social Sciences 20 (SPSS Inc. Chicago). Results were presented in tabular and graphical forms. Mean, median, standard deviation and ranges were calculated for quantitative data. The Chi square analysis was used in testing for significant differences between proportions and frequencies. The T-test was used in testing for significant differences between two means. The confidence interval was set at 95% limit, with level of significance, p≤0.05.

Results

50 patients were enrolled in the study. The age distribution of the subjects was between 19 to 72 years with mean age of patients 54.8±15.75 years. 31 (62%) were males and 19 (38%) were females. It was established that 58% of our study subjects were hypertensive, 76% were smokers, 32% were alcoholics and 34% had family history of CVA (Table 1).

Analysis of lipid profile among both the groups of stroke, i.e., hemorrhagic and ischemic stroke, revealed that the most common rate deranged in the ischemic group was decreased HDL, which is deranged in 54.1% of patients and the second most common rate deranged was increased VLDL, which was deranged in 40.5%. Among the hemorrhagic group the most common deranged rate was also decreased HDL, which was deranged in 46.1% of patients, and the second most common deranged rate was increased total cholesterol, which was deranged in 53.8% of patients (Table 2).

Our study concluded a significant association between serum total cholesterol, triglycerides, LDL level, VLDL level and risk of stroke. High levels of total cholesterol, triglycerides, LDL cholesterol were associated with higher risk of stroke. Lowered HDL cholesterol levels were not significantly associated with stroke. The ratio of HDL/LDL cholesterol, TC/HDL cholesterol for males and females was evaluated. However, the association with risk of stroke was not found (Table 3).

Discussion

Association of Total Cholesterol to the Non-Diabetics with Stroke

Our study involved 50 subjects and total cholesterol was elevated in the non-diabetics with stroke. The serum total cholesterol levels in cases of either ischaemic or haemorrhagic

| Variables          | Hemorrhagic Stroke (n=13) | Ischemic Stroke (n=37) | Chi-square test |

| Absent             | 8 (61.5)                 | 25 (67.6)              |                 |
stroke were high (10%) (total cholesterol >240 mg% according to the Adult Treatment Panel (ATP) – the 3rd guidelines of National Cholesterol Education Program (NCEP)).

Similar studies by Sreedhar K et al. [5] Benfante et al. [6], Di Mascio et al. [7] showed both ischemic and hemorrhagic stroke were associated with increased cholesterol levels.

Contrary to our study, Iso et al. [8] emphasized an inverse association between serum cholesterol level and hemorrhagic stroke. There was no correlation between serum cholesterol and risk of stroke in a study by Harmsen et al. [9] Rastenyte et al. [10] and Hart CL et al. [11] 2000 showed serum triglycerides in normal range in the study on stroke.

Association of Serum HDL Cholesterol to the Non- Diabetics with Stroke

It was established that serum triglycerides were high in 23.1% of hemorrhagic stroke patients and 13.5% of ischemic stroke patients (>200 mg% according to ATP – 3rd guidelines). Sreedhar K et al. [5] in his study showed 80% of non-diabetic stroke patients with S.triglyceride >200mg/dl had ischemic stroke and the other 20% had hemorrhagic stroke. Tilvis R.S et al. [12] in his study showed serum triglyceride was higher in ischemic stroke. Farid et al. [13] also had similar results in his study in 1972. Hachinski et al. [14] showed a positive association of triglycerides in patients with atherothrombotic stroke and transient ischemic attacks compare to the control subjects. Albucher J.K et al. [15] 2000 showed serum triglycerides in normal range in the study on stroke.

Association of Serum HDL Cholesterol to the Non- Diabetics with Stroke

In the study of HDL cholesterol in stroke patients, it was found out that the ischemic group (54.1%) patients had greater abnormal levels (<40mg% according to ATP – 3rd guidelines) than the haemorrhagic group (46.1%). Simons et al. [16] study clearly indicated HDL – cholesterol as the only lipid associated with stroke risk. It emphasised the need for management of low HDL cholesterol in young patients regardless of atherosclerosis.
Association of Serum LDL Cholesterol to the Non-Diabetics with Stroke

Among ischemic stroke cases, 16.2% had high LDL cholesterol and this was 15.4% among haemorrhagic stroke cases. Sreedhar K et al. [5] showed that high levels of serum LDL cholesterol had significant risk of ischemic stroke in the non-diabetics. Botet et al. [18] and Hachinski et al. [14] showed positive correlation between LDL cholesterol levels and risk of stroke. Kurth T et al. [19] 2007 showed remarkable increase in serum LDL levels in ischemic stroke patients.

Association of Serum VLDL Cholesterol to the Non-Diabetics with Stroke

In our study, among ischemic stroke cases 40.5% had increased VLDL cholesterol and this was 53.8% among haemorrhagic stroke cases. Bidyadhar et al. [20] 1984 showed that VLDL was increased in their study on stroke. Sreedhar K et al. [5] in the study showed that high VLDL was not associated with risk of stroke in non-diabetic patients.

Conclusions

According to our study the conclusion can be drawn that the most common type of lipid abnormality were abnormal triglycerides, abnormal VLDL, abnormal LDL. So, these parameters should be considered while predicting the risk of stroke in a dyslipidemic patient. Stroke patients with dyslipidemia need a comprehensive health care approach involving dietician, physician and good bio chemistry back up. In Indian scenario, where majority of the patients belong to the low socio-economic status, life style modification plays a more important role in prevention and management of stroke and dyslipidemia in contrast to high cost of lipid lowering agents.
