An online pilates exercise program is effective on proprioception and core muscle endurance in a randomized controlled trial

Sinem Suner-Keklik1 · Ayse Numanoğlu-Akbas1 · Gamze Cobanoglu2 · Nihan Kafa2 · Nevin A. Guzel2

Abstract

Background Proprioception is important for stability of body segments, postural control, and functionality. However, there are no studies in literature showing effects of online Pilates exercises that create proprioceptive inputs on vertebra on trunk proprioception.

Aims This study aims to reveal effect of online Pilates exercises conducted on trunk proprioception and core muscle endurance in healthy individuals.

Methods We included thirty-three healthy individuals between ages of 18 and 25 in study. Individuals were randomly divided into two groups. There were 17 individuals in Pilates group (PG), and 16 individuals in control group (CG). The PG was given online Pilates exercises by the physiotherapist in groups 3 days a week for 6 weeks, 1 h a day. There was no exercise program recommended for individuals in CG. We evaluated trunk proprioception with an inclinometer, core muscle endurance with three core endurance tests created by McGill, and prone bridge tests. All evaluations completed just before start of study and 2 days after 6-week training.

Results Two groups had similar demographic characteristics, and there was no difference between baseline measurements (p > 0.05). While improvement observed in PG in trunk proprioception and all of core muscle endurance tests (p < 0.05), no statistically significant difference reported in CG (p > 0.05).

Conclusions We revealed that online Pilates exercises performed at mat level for 6 weeks in healthy individuals had positive effects on trunk proprioception and core muscle endurance with this study. Contribution of Pilates exercises to development of both muscular endurance and proprioceptive senses, even if performed at a distance, is important.

Keywords Core muscle endurance · Online exercise · Pilates · Proprioception

Highlights

- Online Pilates exercises had positive effects on trunk proprioception and core muscle endurance.
- Online Pilates exercises with a physiotherapist are a type of tele-exercise that provides beneficial gains.

Introduction

Tele-exercise services provided in the scope of telehealth services show beneficial effects and may be an important approach during the Coronavirus disease 2019 (COVID-19) pandemic, where normal daily activities and health protection systems are disrupted or changed [1]. Innovative approaches are required to prevent functional decline in individuals under social distance and quarantine conditions. However, this is a requirement not only for pandemic conditions but also for individuals living in rural areas under normal conditions. Telehealth exercise programs are one way to provide physical activity [1]. Online Pilates exercises in the pandemic are one of the exercise approaches that will keep individuals active [2].

Pilates, developed by Joseph Pilates in the 1900s and gradually becoming widespread, is an exercise approach
that aims to increase the endurance, strength, and flexibility of the core muscles and improve balance and dynamic postural control [3]. The primary goal in Pilates exercises is to increase the stability and strength of the transversus abdominis, multifidus, pelvic floor, and diaphragm muscles, which are known as core muscles, and to increase the flexibility of the lumbar region muscles, thus reducing the compression on the vertebra [4]. Because of the neutral spine position used during Pilates exercises, a balanced co-contraction can be created in the core muscles, thereby achieving mechanical stability in the lumbar vertebra and reducing the load on the vertebra [5].

Functionally, the core is a kinetic link that facilitates the transfer of torque and angular momentum between the upper and lower extremities in sports skills, professional skills, fitness activities, and daily living activities, in the execution of whole body movements [6]. Core muscles play an important role in reducing the risk of injury and stabilizing peripheral joints, especially during high physical activity [7]. Furthermore, core stability fires body mechanisms that allow for the maximization of the force exerted while minimizing the loads placed on the proximal joints [8, 9].

Proprioception is defined as the afferent entry of internal stimuli responsible for the stability of body segments, postural control, and several conscious senses, taken by proprioceptive fibers [10]. Proprioceptive signals are derived from mechanoreceptors located in ligaments, facet joints, intervertebral discs, and muscles. Among these structures, dense muscle spindles reported in paraspinal rotators are considered to be very important in controlling trunk movement [11]. Any deficiency in proprioception will affect the quality of movement because the ability to control trunk movement is necessary to establish the correct movement pattern [11].

Previous studies have shown the effects of the Pilates exercise programs on core muscle endurance using different methods [12–15]. However, there are no studies showing the effects of Pilates exercises, which are based on core muscle activity and create proprioceptive inputs on the vertebra, on trunk proprioception. Moreover, there is no other study in the literature that demonstrates the effectiveness of online Pilates exercises for healthy individuals within the scope of telehealth services. For these reasons, this study aims to investigate the effect of online Pilates training on trunk proprioception and core muscle endurance in healthy individuals.

Materials and methods

Participants

We conducted the study in Sivas Cumhuriyet University Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation. Ethical approval obtained from Sivas Cumhuriyet University, Non-Interventional Clinical Research Ethics Committee with the decision number 2018–018/23 dated 26.02.2018. This study has been conducted in accordance with the principles set forth in the Helsinki Declaration.

In the study, we included healthy volunteers between the ages of 18 and 25 and excluded individuals with vertebral pathology; with a history of pain, surgery, injury, or trauma in the lumbar region; and those with a neurological, systemic, or degenerative disease. We designed the study as a randomized, controlled, single-blind study. In addition, individuals who participated in a regular exercise program for the last 6 months were excluded. We used a computer program for randomization and placed the individuals who completed the first evaluation in the Pilates group (PG) or control group (CG) randomly. We explained the purpose and content of the study to the participants before the study. Furthermore, the participants signed an informed consent form that they would participate in the study voluntarily.

Procedures

We assessed the participants by an experienced physiotherapist, who was blind to the randomization, at the start of the study and 2 days after the 6-week training. The group to which they depended was not disclosed to the participants until the end of the baseline evaluation. We performed the Pilates exercises online, under the supervision of another certified physiotherapist with 13 years of experience. We asked the individuals not to inform the evaluator of their involvement in the training during the last evaluation.

Outcome measurements

We recorded demographic information (age, body weight, height, body mass index) of the participants.

We performed the evaluation of trunk proprioception by the active angle repetition test in a standing position using Dualer IQ Digital Inclinometer (J-Tech Medical, Midvale, UT, USA). One part of the inclinometer placed on the first lumbar vertebra and the other part on the sacrum [16]. The test started in an upright position. We asked the individuals to flex the trunk until reaching the target angle of 30° in the sagittal plane and to maintain this position for 3 s then to come back to an upright position [17]. After the target angle was felt by the individuals three times in total, we asked the individuals to identify the perceived target angle three times as accurately as possible. The difference between the target angle perceived by the individuals and the angle found again by the individuals was averaged [18].

We evaluated the core muscle endurance by using three core endurance tests created by McGill and the prone bridge test. The McGill endurance tests are the trunk flexor test, the trunk extensor test, and the side bridge test. We
performed a trunk flexor test with the trunk at 60° flexion and knees and hips at 90° flexion. The arms were crossed over the chest and individuals were asked to maintain this position for as long as possible. We performed a trunk extensor test in a prone position on the treatment table. The pelvis, hips, and knees were fixed on the treatment table, up to the spina iliaca anterior superior. We asked individuals to maintain a horizontal body position for as long as possible, with arms crossed over their chests. We performed the side bridge test on the mat, on the dominant and non-dominant sides, respectively, while lying down. The body weight of the participants was supported only by the lower elbows and feet while lifting their hips up on the mat. The test was stopped when the side-lying position was lost or the hips returned to the mat [19]. We performed a prone bridge test on the mat in the prone position and with support from the elbows. The elbows of the participants were placed under their shoulders, leaving a narrow space between their feet. We asked them to raise their hips and torso on their forearms and toes and to maintain a straight position. All core endurance tests terminated when positions were distorted. Measurement results were recorded in seconds [20].

Intervention

Pilates training was done by a certified and 13-year experienced physiotherapist and lasted a total of 6 weeks, 3 days a week for 1 h. Exercises were performed online because of the pandemic. Microsoft Teams program was used to perform the exercises online. We divided the individuals in the Pilates exercise group into two smaller groups of 10 and 11 to verify whether they correctly did the exercises. Pilates practitioners usually practice a simple series of exercises that include repetitive, low-intensity flexibility and muscular endurance exercises, with muscular movements in the abdominal, lower back, hips, and thighs [3]. In this study, we organized a program to include 10 min of warm-up, 40 min of Pilates exercises, and 10 min of cooling and stretching exercises, and the exercises were done in 10 repetitions. The Pilates exercise program included the following exercises: hundreds, shoulder bridge, clam, sidekick, arm opening, abdominal preparation, one leg stretch, breaststroke preparations, cobra, swimming, and oblique roll-up. During the Pilates exercises, we described the exercises with different visual simulation techniques, and exercises were done together with Pilates breathing. We instructed the subjects to breathe through the nose before starting the movement and to complete the movement while exhaling through their teeth by contracting their lips [21]. No exercise recommendations were made for the control group, and individuals were asked to continue their routine activities.

Data availability

The data associated with the paper are not publicly available but are available from the corresponding author on reasonable request.

Statistical analysis

We performed statistical analysis by using SPSS software, version 21 (SPSS Inc. Chicago, IL, USA). The normal distribution of variables was determined using histograms, probability plots, and a Shapiro–Wilk test. Because of an abnormal distribution, median and interquartile range (IQR) were used for descriptive statistics. We used a Mann–Whitney U test to compare baseline and change values between groups. We used Wilcoxon Test for comparing baseline values within the group and values after 6 weeks. The level of significance was set at \( p < 0.05 \) for all analyses. The effect sizes were evaluated according to Cohen’s \( d \) standards within the pre-post differences. Effect size results were interpreted as small (\( ≥ 0.2 \)), medium (\( ≥ 0.5 \)), or large (\( ≥ 0.8 \)) according to guidelines [22].

Results

Within the scope of the study, we invited 44 healthy individuals for evaluation. Participants who did not come to the final measurement and did not complete the Pilates training because of personal reasons were excluded from the study. Consequently, 17 individuals from PG and 16 individuals from CG completed the study. Figure 1 shows the CONSORT flow diagram showing the participants in the study.

In the post hoc power analysis for the study, the effect size calculated considering the proprioception values was 1.041. When 17 individuals were included in PG and 16 individuals were included in CG, we calculated that the power of the study was 0.89.

The two groups had similar characteristics in terms of demographic characteristics (\( p > 0.05 \), Table 1), and there was no difference between baseline measurements (\( p > 0.05 \), Table 2).

In all of the proprioception sense and core muscle endurance tests, although the exercises were performed remotely online, PG was improved (\( p < 0.05 \), Table 2), while there was no statistically significant difference in CG (\( p > 0.05 \), Table 2). Since we compared the groups in terms of changes, there was no difference between the two groups in terms of proprioception sense (\( p > 0.05 \), Table 2), but there was a difference in other parameters (\( p < 0.05 \), Table 2).
Discussion

This study, which we think is the first to investigate the effect of online Pilates exercise programs on trunk proprioception, has shown that a 6-week online Pilates exercise program is effective in improving trunk proprioception and core muscle endurance.

Proprioception plays an important role in motor control, and purposeful action is not possible without proprioceptive feedback [23]. A study examining the influence of trunk proprioception from a postural position in healthy individuals indicated that a decreased perception of the joint position may increase the risk of low back pain or injury [24]. This reveals the requirement for exercises that improve trunk proprioception. A study investigating the effects of 5-week Pilates exercises on dynamic balance demonstrated that, although proprioceptive sensation was not evaluated, providing feedback with verbal and tactile cues to correct erroneous movement patterns during the exercises may have increased kinesthetic awareness. This study demonstrated that increased kinesthetic awareness resulted in improved motor control [25]. Our study indicated that the 6-week online Pilates exercise program provided a significant improvement in trunk proprioception. This result highlights the effectiveness of online Pilates exercises in preventing proprioceptive losses. As our study shows, online Pilates exercises are an exercise approach that improves trunk proprioception and can be included among the preventive approaches in healthy individuals. Because there are no other studies investigating the effect of Pilates on trunk proprioception, a literature comparison on this subject could not be performed.

Core or trunk muscle strength is important for the successful performance of sports or daily activities [6]. One of the goals of Pilates exercises is to strengthen and train the core muscles for the control of trunk movement in all three planes [26, 27]. Pilates exercises focus on strengthening the core muscles to stabilize the trunk [28]. There are many studies investigating the effects of Pilates exercises on trunk muscle endurance in healthy individuals. A systematic review including 16 randomized controlled trials that examined the effectiveness of Pilates in healthy individuals provided moderate evidence for improving muscular endurance [12]. Nine randomized controlled trials on the effect of Pilates exercises on healthy individuals were discussed in another systematic review. These results demonstrated that Pilates exercises performed two to three times a week for 5–12 weeks increased abdominal muscle endurance in both genders [29]. In another study involving 50 healthy individuals, the participants were divided into control and Pilates groups. While the participants in the Pilates group followed a 1-h Pilates exercise program 2 days a week for 12 weeks, the control group continued their routine activity level. The study showed that trunk flexor muscle endurance increased in the Pilates group [3]. These studies support our results in terms of showing that Pilates exercises increase core muscle endurance in healthy individuals. Our results demonstrated that there was a significant improvement in the Pilates group [3]. These studies support our results in terms of showing that Pilates exercises increase core muscle endurance in healthy individuals. Our results demonstrated that there was a significant improvement in the Pilates group in all core endurance tests. Although there are studies in the literature showing that Pilates exercises increase core muscle endurance, there is no study investigating the effect of online Pilates exercises on core muscle endurance. In this respect, our study has a unique value.

Telehealth exercise protocols have been developed to assist people living in different conditions [30, 31]. In the COVID-19 pandemic, where people around the world require to be isolated to prevent the spread of the virus, telehealth exercise practices have become more important [32]. Home exercises may be safer than gymnasiums to avoid an increase in pandemic cases [33]. We conducted

Table 1 Demographic characteristics of the participants

|                  | PG (n = 17) | CG (n = 16) | p     |
|------------------|------------|------------|-------|
| Age (years)      | 22 (20–23) | 20.5 (20–22)| 0.407 |
| Body weight (kg) | 58 (54–68) | 59 (55–67) | 0.787 |
| Height (cm)      | 164 (160–170) | 167.5 (164–171) | 0.406 |
| BMI (kg/m²)      | 20.9 (19.31–23.3) | 21.15 (19.36–24.17) | 0.773 |

Data are presented as Median (IQR). *p < 0.05, PG Pilates group, CG control group, BMI body mass index.
our work on an online platform as it may pose a risk to perform breath-focused Pilates exercises face-to-face in the pandemic. Thus, we had the chance to demonstrate the effect of online Pilates exercises performed with a physiotherapist on trunk proprioception and core muscle endurance. Online Pilates exercises with a physiotherapist are a type of tele-exercise that increases physical activity and provides beneficial gains in situations where it is a risk to be in crowded environments such as the COVID-19 pandemic or when access to exercise centers is not available. Our study is the first study in the literature to examine the effects of Pilates exercises on trunk proprioception. Moreover, it is the first study to reveal the effects of online application of Pilates exercises. There is a requirement for future studies examining the effect of Pilates exercises on trunk proprioception in individuals of different age groups and with different pathologies. To demonstrate whether online Pilates training is as effective as face-to-face Pilates training, additional studies are required to compare online Pilates training with face-to-face Pilates training.
