Functions of several Cayley-Dickson variables and manifolds over them.

S.V. Lüdkovsky

31 May 2004

Abstract

Functions of several octonion variables are investigated and integral representation theorems for them are proved. With the help of them solutions of the $\partial$-equations are studied. More generally functions of several Cayley-Dickson variables are considered. Integral formulas of the Martinelli-Bochner, Leray, Koppelman type used in complex analysis here are proved in the new generalized form for functions of Cayley-Dickson variables instead of complex. Moreover, analogs of Stein manifolds over Cayley-Dickson graded algebras are defined and investigated.

1 Introduction

In previous papers functions of one quaternion and Cayley-Dickson variables were investigated [19, 20]. In them superdifferentiability of functions was studied and the theory of holomorphic functions was investigated. It was done with the help of line integration introduced and studied there. This line integration restricted on complex functions gives ordinary Cauchy integral, but ordinary Cauchy integral can not be in the usual manner extended on continuous functions of Cayley-Dickson numbers.

This line integral is additive by rectifiable paths and continuous functions in open domains in Cayley-Dickson algebras $\mathcal{A}_p$, it is also $\mathbb{R}$-homogeneous and left and right linear over quaternions, but generally nonlinear relative to quaternions or octonions or Cayley-Dickson algebras of higher order. Over Cayley-Dickson algebras of higher order than quaternions left or right linearity of operators certainly undermines relations between ordered (associated) products of generators of Cayley-Dickson numbers, for example, $(ij)l = -i(jl)$ for generators of the octonion algebra $\mathbf{O}$, where $\{1, i, j, k\}$ are standard generators of the quaternion algebra $\mathbf{H}$, $l$ is the generator of doubling procedure of the construction of $\mathbf{O}$ from $\mathbf{H}$ [1, 12]. The line integral over Cayley-Dickson algebras for $z$-superdifferentiable (that is, $\mathcal{A}_p$-holomorphic) functions in corresponding domains $U$ depends only on specific homotopy classes of rectifiable paths with given initial and final points and also satisfies at least locally

$$\frac{\partial}{\partial z} [\int_{\gamma_z} f(\xi) d\xi] / \partial z \cdot 1 = f(z),$$

for example, in a ball $B$ in $U$, where $\gamma_z : [0, 1] \to U$, $\gamma(0)$ and $\gamma(1) = z \in B$.

The Cayley-Dickson algebra is $\mathbb{Z}_2$-graded, that is, superalgebra. In the theory of superalgebras it was traditionally used the notion of superdifferentiability (left or right superlinear) [8]. It causes strong restrictions on the types of admissible functions. For example, over Grassman algebras it produces functions only linear in odd arguments [2, 4]. In general it leads to conditions analogous to Cauchy-Riemann.
Cayley-Dickson algebras such as quaternion and octonion algebras have found applications in quantum mechanics and noncommutative geometry [3, 5, 13, 21, 24]. The latter is especially valuable in conjunction with operator algebras, which permits to consider quantization. On the other hand, Cayley-Dickson algebras are not central over the field of complex numbers \( \mathbb{C} \). Moreover, the octonion algebra and Cayley-Dickson algebras of higher order can not be written as matrices with entries in the field of real or complex numbers, though their centre is \( \mathbb{R} \).

It is necessary to note, that apart from the real or complex case derivatives of superdifferentiable functions of Cayley-Dickson numbers are operators even in the case of one variable. To work with rings of superdifferentiable functions it was introduced the condition of \( A_p \)-additivity instead of right or left superlinearity of a superdifferential [19, 20]. It is natural, since if to start from the family \( \mathcal{F} \) of all right superlinearly superdifferentiable functions \( f : U \to A_p, \ p \geq 2 \), then the using of Leibnitz rule for finite ordered (associated) products \( \{f_1, ..., f_m\}_{q(m)} \) of \( f_1, ..., f_m \in \mathcal{F} \) gives only \( \mathbb{R} \)-homogeneous \( A_p \)-additive superdifferential, where \( U \) is open in \( A_p^n \), a vector \( q(m) \) indicates on the order of multiplication. This superdifferential operator can be extended on the corresponding family of converging series arising from such final products and hence on locally analytic functions of \( z_1, ..., z_n \in A_p \). Since there are many embeddings of \( \mathbb{C} \) into \( A_p, \ p \geq 2 \), then to encompass the case of complex holomorphic functions in such theory it was introduced the condition analogous to holomorphicity: \( \partial f/\partial z = 0 \), where \( z \bar{z} = |z|^2, \bar{z} \) denotes the adjoint of a Cayley-Dickson number \( z \).

To make it accurately it was used the notions of words and phrases and germs of functions and the Stone-Weierstrass theorem. On the other hand, such formalized definition of superdifferentiability does not impose from the beginning the condition of local analyticity. It was proved in [19, 20] under definite conditions equivalence of Cayley-Dickson holomorphicity, independence of the line integral over \( A \) of integral representation formulas for them. Moreover, such formulas are also obtained for differential forms over \( A_p, \ p \geq 2 \), where \( A_2 = H, A_3 = O \). There are well-known integral formulas of the Martinelli-Bochner, Leray, Koppelman type widely used in complex analysis.
Here new generalized formulas are proved for functions of Cayley-Dickson variables instead of complex. Moreover, analogs of Stein manifolds over Cayley-Dickson graded algebras are defined and investigated.

The results of this paper it is possible to apply for further investigations of transformation (super)groups and corresponding to them (super)algebras of manifolds over Cayley-Dickson algebras as well as loop spaces, measures and stochastic processes on them, continuing previous studies of groups of loops and groups of diffeomorphisms of Riemannian and complex manifolds [15, 16, 17, 18], for they are widely used in mathematical physics and gauge theories.

2 Differentiable functions of several Cayley-Dickson variables

2.1. Theorem. Let $U$ be an open subset in $\mathcal{A}_r$, $2 \leq r < \infty$, with a $C^1$-boundary $\partial U$ $U$-homotopic with a product $\gamma_1 \times \gamma_2 \times \ldots \times \gamma_m$, where $m = 2^r - 1$, $\gamma_j(\theta) = a_j + \rho_j \exp(2\pi \theta M_j)$, $M_j \in \mathcal{I}_r$, $|M_j| = 1$, $\theta \in [0, 1]$, $\gamma_j([0, 1]) \subset U$, $0 < \rho_j < \infty$, $j = 1, 2, \ldots, m$, where $M_1, \ldots, M_m$ are linearly independent over $\mathbb{R}$. Let also $f : cl(U) \to \mathcal{A}_r$ be a continuous function on $cl(U)$ such that $(\partial f(z)/\partial \bar{z})$ is defined in the sense of distributions in $U$ is continuous in $U$ and has a continuous extension on $cl(U)$, where $U$ and $\gamma_j$ for each $j$ satisfy conditions of Theorem 3.9 [20], where $\mathcal{I}_r := \{z \in \mathcal{A}_r : z + \bar{z} = 0\}$. Then

\[
(\partial_{z_2} \ln(\zeta_2 - 3\zeta_3))M^*_2 \ldots [[(\partial_{z_m} \ln(\zeta_m - z))M^*_m] \wedge (\partial_{z_{m+1}} \ln(\zeta_m - z))M^*_m] = 0 \quad \forall \zeta \in I,
\]

Proof. We have the identities $d_\zeta[f(\zeta)/(\partial \zeta \ln(\zeta - z))] = \{(\partial f(\zeta)/\partial \zeta).d\zeta\} \wedge (\partial \zeta \ln(\zeta - z))$ and $d_\zeta d_\zeta \ln(\zeta - z)_{|\zeta = \gamma_1} = 0$ for $\zeta$ varying along a path $\gamma$, where for short $f(z) = f(z, \bar{z})$, since there is the bijection of $z$ with $\bar{z}$ on $\mathcal{A}_r$. There exists $\mathbb{R}$-homogeneous $\mathcal{A}_r$-additive operator-valued function $q(\zeta, z)$ such that $\partial \zeta \ln(\zeta - z) = q(\zeta, z).d\zeta$ (see also §§2.1, 2.2, 2.6 and 2.7 [20]). As in [19, 20] $f(z, \bar{z}) := \partial g(z, \bar{z})/\partial z$, where $g(z, \bar{z})$ is an $\mathcal{A}_r$-valued function such that $(\partial g(z, \bar{z})/\partial z).1 = f(z, \bar{z})$. Since $\zeta_1$ varies along the path $\gamma_1$, then $d_\zeta \wedge (\partial \zeta |_{\zeta = \gamma_1} = 0$. Consider $z \in U$ and $\epsilon > 0$ such that the torus $T(z, \epsilon, \mathcal{A}_r)$ is contained in $U$, where $\partial T(z, \epsilon, \mathcal{A}_r) = \psi_m \times \cdots \times \psi_2 \times \psi_1$, $\psi_j$ are of the same form as $\gamma_j$ but with $z$ instead of $a_j$ and with $\rho_j = \epsilon$. Applying Stokes formula for regions in $\mathbb{R}^{2^r}$ and componentwise to $\mathcal{A}_r$-valued differential forms we get

\[
\int_{\partial U} w - \int_{\partial T(z, \epsilon, \mathcal{A}_r)} w = \int_{U \setminus T(z, \epsilon, \mathcal{A}_r)} dw, \quad w = \ldots([\partial_{z_1} \ln(\zeta_1 - \zeta_2)]M^*_1) \ldots [([\partial_{z_m} \ln(\zeta_m - z))M^*_m] = 0 \quad \forall \zeta \in I,
\]

$m = 2^r - 1$. Then $(d \ln \exp(\theta M))M^* = d \theta$ and $\dot{f}(z).d \theta = f(z).d \theta$, since $M \in \mathcal{I}_r$, $M \neq 0$ and $\theta \in \mathbb{R}$. In view of Theorems 3.9 and 3.23 [20] we have that

\[
\lim_{\epsilon \to 0, \epsilon > 0} 2\pi^{-m} \int_{\gamma_m} \ldots (\int_{\gamma_2} (f_{\gamma_1} w)) = f(z) \quad \forall \zeta \in I.
\]
\[
\lim_{x \to 0, \varepsilon > 0} \int_{U \cap T(x, \varepsilon, A_r)} d\omega = \int_U d\omega.
\]

From this formula (1) follows.

2.1.1. Remark. Formula (2.1) is the Cayley-Dickson algebras’ analog of the (complex) Cauchy-Green formula. Since in the sense of distributions \( \partial f / \partial \bar{z} = \partial (\partial g / \partial \bar{z}) / \partial z \) (see Definition 1), then from \( \partial f / \partial \bar{z} = 0 \) it follows, that \( \partial f / \partial \bar{z} = \partial f / \partial z = 0 \). If \( \partial f / \partial \bar{z} = 0 \), then \( g \) can be chosen such that \( \partial g / \partial \bar{z} = 0 \) [20]. Therefore, from Formula (2.1) it follows, that \( f \) is \( A_r \)-holomorphic in \( U \) if and only if \( \partial f / \partial \bar{z} = 0 \) in \( U \).

2.2.1. Remark. Instead of curves \( \gamma \) of Theorem 2.1 above or Theorems 3.9, 3.23 [20] it is possible to consider their natural generalization \( \gamma(\theta) + z_0 = z_0 + \rho(\theta) \exp(2\pi i S(\theta)) \), where \( \rho(\theta) \) and \( S(\theta) \) are continuous functions of finite total variations, \( \theta \in [0, 1] \subset \mathbb{R}, \rho(\theta) \geq 0, S(\theta) \in \mathcal{L}_r, 2 \leq r \leq \infty \). Therefore, \( \gamma \) is a rectifiable path. If \( S(0) = S(1) \mod(\mathcal{S}_r) \) and \( \rho(0) = \rho(1) \), then \( \gamma \) is a closed path (loop):

\[
\gamma(0) = \gamma(1), \text{ where } \mathcal{S}_r := \{z \in \mathcal{L}_r : |z| = 1\}, \mathcal{L}_r := \{z \in A_r : z + \bar{z} = 0\}.
\]

Consider \( S \) absolutely continuous such that there exists \( T \in L^1([0, 1], \mathcal{S}_r) \) for which \( S(\theta) = S(0) + \int_0^\theta T(t) \, dt \) (see Satz 2 and 3 (Lebesgue) in §6.4 [11]) and let \( \rho(\theta) > 0 \) for each \( \theta \in [0, 1] \). Evidently, \( M_n := S(1) - S(0) = \int_0^1 T(t) \, dt \) is invariant relative to reparametrizations \( \phi \in Diff^1_+([0, 1]) \) of diffeomorphisms of \([0, 1]\) preserving the orientation, \( n \) is a real number, \( M \in \mathcal{S}_r \). Then \( \Delta Arg(\gamma) := Arg(\gamma)|_0^1 = 2\pi \int_0^1 T(t) \, dt \) (see also Formula (3.7) and §3.8.3 [20]). In view of Theorem 3.8.3 [20] for each loop \( \gamma : \Delta Arg(\gamma) \in \mathcal{Z} \mathcal{S}_r \). For each \( \epsilon > 0 \) for the total variation there is the equality \( V(\gamma \epsilon) = V(\gamma) \epsilon \).

Since \( \gamma([0, 1]) \) is a compact subset in \( A_r \), then there exists \( \rho_m := \sup_{\theta \in [0, 1]} \rho(\theta) < \infty \). Hence \( z_0 + (\gamma(\epsilon)([0, 1]) \subset B(A_r, z_0, \rho_m \epsilon) \).

Therefore, Theorems 3.9, 3.23, 3.28 and Formulas (3.9, 3.34.i) [20] and Theorem 2.1 above are true for such paths \( \gamma \) also and Formula (3.9) [20] takes the form

\[
(1) \quad f(z) M = (2\pi n)^{-1} \left( \int_{\psi} f(\xi)(\zeta - z)^{-1} \, d\zeta \right),
\]

where \( 0 \neq n \in \mathbb{Z} \) for a closed path \( \gamma, M \in \mathcal{S}_r \), Formula (1) generalizes Formula (3.9), when \( |n| > 1 \). When \( \int_{\psi}(0, \gamma) = 0 \), then \( \left( \int_{\psi} f(\zeta)(\zeta - z)^{-1} \, d\zeta \right) = 0 \) (see also §3.23 [20]).

2.2.2. Note and Definition. Let \( \Lambda \) denotes a Hausdorff topological space with non-negative measure \( \mu \) on an \( \sigma \)-algebra of all Borel subsets such that for each point \( x \in \Lambda \) there exists an open neighborhood \( U \ni x \) with \( 0 < \mu(U) < \infty \). Consider a set of generators with real algebra \( \{i_x : x \in \Lambda\} \) such that \( i_x i_y = -i_y i_x \) for each \( x \neq y \in \Lambda \setminus \{0\} \) and \( i_x^2 = -1 \) for each \( x \in \Lambda \setminus \{0\} \), where 0 is a marked point in \( \Lambda \). Add to this set the unit \( 1 := i_0 \) such that \( a i_x = i_x a \) for each \( a \in \mathbb{R} \) and \( x \in \Lambda \). In the case of a finite set \( \Lambda \) the Cayley-Dickson algebra generated by such generators is isomorphic with \( A_{N-1} \), where \( N = card(\Lambda) \) is the cardinality of the set \( \Lambda \).

For the infinite subset of generators \( \{i_0, i_{x_j} : j \in \mathbb{N}, x_j \in \Lambda\} \) the construction from §3.6.1 [20] produces the algebra isomorphic with \( A_{\infty} \). Here, consider the case \( card(\Lambda) > N_0 \).

Due to the Kuratowski-Zorn lemma we can suppose, that \( \Lambda \) is linearly ordered and this linear ordering gives intervals \( (a, b) := \{x \in \Lambda : a < x < b\} \) being \( \mu \)-measurable, for example, \( \Lambda = \mathbb{R}^n \times (\mathbb{R}/\mathbb{Z})^m \) has the natural linear ordering induced by the linear ordering from \( \mathbb{R} \) and by the lexicographic ordering in the product, where \( n, m \in \mathbb{N} \).

Then consider a finite partition \( \Lambda \) into a disjoint union \( \Lambda = \bigcup_{j=0}^p A_j \), where \( x < y \) for each \( x \in A_j \) and \( y \in A_l \) for \( j < l \leq p, p \in \mathbb{N}, 0 \in A_0 \). The family of such partitions we denote \( \mathcal{Z} \). Let \( T \in \mathcal{Z}, x_j \in A_j \) be marked points. Then there exists a step function \( f_T \) such that \( f_T(x) = C_j i_{x_j} \) for each \( x \in A_j \), where \( C_j \in \mathbb{R} \). Consider the norm \( \|f_T\|^2 := \int_{\Lambda} f_T(x)^2 \, \mu(dx) \), where \( f_T(x) := C_0 \chi_A(x) \delta_{0,x_0} - \sum_{x_j \neq 0} C_j \chi_{A_j}(x) i_{x_j}, \chi_A(x) = 1 \) for \( x \in A \), \( \chi_A(x) = 0 \) for \( x \notin A \), \( \delta_{x,y} = 1 \) for \( x = y \), \( \delta_{x,y} = 0 \) while \( x \neq y \). To each \( f_T \) put the element \( z_{f_T} := \sum_j C_j i_{x_j} \mu(A_j) \).
The algebra which is the completion by the norm $\| * \|_\Lambda$ of the minimal algebra generated by the family of elements $z_{f_r}$ for $f_r$ from the family $\mathcal{F}$ of all step functions and all their ordered final products we denote by $\mathcal{A}_\Lambda$.

2.2.3. Theorem. The set $\mathcal{A}_\Lambda$ is the power-associative noncommutative nonassociative algebra over $\mathbb{R}$ complete relative to the norm $\| * \|_\Lambda$ with the centre $Z(\mathcal{A}_\Lambda) = \mathbb{R}$, moreover, there are embeddings $\mathcal{A}_\infty \hookrightarrow \mathcal{A}_\Lambda$ for $\text{card}(\Lambda) \geq \aleph_0$. The set of generators of the algebra $\mathcal{A}_\Lambda$ has the cardinality $\text{card}(\Lambda)$ for $\text{card}(\Lambda) \geq \text{card}(\mathbb{N})$. There exists the function $\exp(\int_\Lambda f(x)\mu(dx))$ of the ordered integral product from $\mathcal{A}_\Lambda$ onto $\mathcal{A}_\Lambda$.

Proof. For $\text{card}(\Lambda) \leq \aleph_0$ the algebra $\mathcal{A}_\Lambda$ is isomorphic with $\mathcal{A}_{\Lambda-1}$ or $\mathcal{A}_\infty$. Thus it remains to consider the case $\text{card}(\Lambda) > \aleph_0$. For each $f_r \in \mathcal{F}$ it can be defined the ordered integral exponential product $\exp(\int_\Lambda f_r(x)\mu(dx)) := \{\exp(C_0\mu(A_0)\pi i_{x_0}/2)\exp(C_p\mu(A_p)\pi i_{x_p}/2)\}_{q(p+1)}$ with $q(p+1)$ corresponding to the left order of brackets. Thus there exist the embeddings of $\mathcal{A}_\infty$ into $\mathcal{A}_\Lambda$. Then $Z(\mathcal{A}_\Lambda) = \mathbb{R}$. The completion of the family $\mathcal{F}$ contains all functions of the type $f(x) = \sum_j f_j(x)\chi_{A_j}(x)i_{x_j}$, where $\{A_j : j \in \mathbb{N}\}$ is the disjoint union of $\Lambda$, each $A_j$ is $\mu$-measurable, $f_j \in L^2(\Lambda, \mu, \mathbb{R})$ and $\lim_{n \to \infty} \sum_{j>n} \|f_j(x)\chi_{A_j}(x)\|^2_{L^2(\Lambda, \mu, \mathbb{R})} = 0$.

Since $\exp(M) = \cos(|M|) + M\sin(|M|)/|M|$ for each $M \in \mathcal{A}_\infty$ and $|\exp(M) - 1| \leq \exp(|M|) - 1$, then for each $f \in \mathcal{A}_\Lambda$ there exists $
lim_{F \ni f_r \to f} \exp(\int_\Lambda f_r(x)\mu(dx)) = \exp(\int_\Lambda f(x)\mu(dx))\right.$ relative to $\| * \|_\Lambda$. From $\exp(\pi i_{x}/2) = i_x$ for each $x \in \Lambda \setminus \{0\}$ it follows, that the family of all elements of the type $\exp(\int_\Lambda f_r(x)\mu(dx))$, $f_r \in \mathcal{F}$ contains all generators of the embedded subalgebra $\mathcal{A}_\infty$ generated by the countable subfamily $\{i_{x_j} : j \in \mathbb{N}\}$.

The completion $\tilde{\mathcal{F}}$ of the family $\mathcal{F}$ by the norm $\| * \|_\Lambda$ is the infinite dimensional linear subspace over $\mathbb{R}$ in $\mathcal{A}_\Lambda$. All possible final ordered products from $\tilde{\mathcal{F}}$ and the completion of their $\mathbb{R}$-linear span by the norm $\| * \|_\Lambda$ produces $\mathcal{A}_\Lambda$. Then for each element from $\mathcal{A}_\Lambda$ there exists the representation in the form of the ordered integral exponential product. Since $\mathcal{A}_\Lambda$ is the algebra over $\mathbb{R}$ and $\text{card}(\Lambda)^{\aleph_0} = \text{card}(\Lambda)$, then the family of generators of the algebra $\mathcal{A}_\Lambda$ has the cardinality $\text{card}(\Lambda)$.

2.2.4. Note. Evidently Propositions 2.2.1, 2.3, 2.6 and Corollary 2.4, Lemma 2.5.1 [20] are accomplished in the case of $\mathcal{A}_\Lambda$ with $b = b_\Lambda$ instead of $b = b_r$. Definition 2.5 has the meaning also for $\mathcal{A}_\Lambda$. Theorem 2.7 is also accomplished for $\mathcal{A}_\Lambda$, since for each $z \in \mathcal{A}_\Lambda$ there exists the embedded subalgebra isomorphic with $\mathcal{A}_\infty$ and containing $z$. A path $\gamma$ is rectifiable, hence it has a countable dense subset. For each $\epsilon > 0$ there exists a subalgebra isomorphic with $\mathcal{A}_\infty$ the projection $\psi(t)$ of which on the path $\gamma$ differs from $\gamma(t)$ no more than on $\epsilon$ for each $t \in [a, b]$, where $\gamma : [a, b] \to \mathcal{A}_\Lambda$. With the help of the projections $P_r$, we have $\psi = \lim_{r \to \infty} P_r(\psi), P_r(\psi) \subset U_r$, $\{P_r(\gamma) : r \in \mathbb{N}\}$, converges to $\psi$ uniformly on the compact segment $[a, b] \subset \mathbb{R}$, where $U_r = P_r(U)$. Take a sequence of such path $\psi_n$ with $\sup_{t \in [a, b]} |\psi_n(t) - \gamma(t)| < 1/n$. Then $\int_{\psi_n} f(z)dz \text{ is the Cauchy sequence in } \mathcal{A}_\Lambda$, which is complete. Thus there exists $\lim_{n \to \infty} \int_{\psi_n} f(z)dz = \int_{\gamma} f(z)dz$. Consequently, the integral along the path has the unique continuous extension on $C^0(U, \mathcal{A}_\Lambda)$. For a continuous function $f$ on an open domain $U$ in $\mathcal{A}_\Lambda$ there exists a generalized operator $f$ in the sense of distributions on rectifiable paths in $U$. Then Definition 1 has the natural extension on $\mathcal{A}_\Lambda$.

In Note 2.8 it can be used $l_2(\mathbb{R})^m$ instead of $\mathbb{R}^{2m}$ and represent the differential forms $\eta$ over $\mathcal{A}_\infty$ as the pointwise limits (or to use the uniform convergence on compact subsets) of differential forms over $\mathcal{A}_r$ for $r$ tending to the infinity, since $z_r \to z$ while $r$ tends to the infinity, where $z \in \mathcal{A}_\infty$, $z_r := P_r(z)$. In the case of $\mathcal{A}_\Lambda$ when $\text{card}(\Lambda) > \aleph_0$ this can be used pointwise, since for each $z \in \mathcal{A}_\Lambda$ there exists a subalgebra isomorphic with $\mathcal{A}_\infty$ and containing $z$. In the general case:
Choose \( \leq d\zeta \) as \( U \) equation \( z \) the \( B \) \( r > 0 \), then power series in \( (z \leq A_\infty,\; 1 \leq p_1 \leq p_2 \leq \ldots \leq p_n \in \mathbb{N}, \; 1 \leq t_1 \leq t_2 \leq \ldots \leq t_n \in \mathbb{N}, \; 0 \leq I_k \in \mathbb{Z}, \alpha_k, \beta_k \in A_\Lambda \) are constants for each \( k = 1, \ldots, n \). \( d^p z^0 := 1, \; d^p \zeta z^0 := 1, \; n \in \mathbb{N}, \; \pi_n(I,U) \subset U_n \) for all \( n \geq \), where \( \pi_n : \Lambda \to \Lambda_n \) is the natural projection for each \( l \geq n \). The convergence on the right side of Formula \((i)\) in the case of an infinite series by \( I \) or \( J \) is supposed relative to \( C_h(W,A_\alpha^n)\)-topology of the uniform convergence on \( W \), where \( W = pr - \lim \{U_n, \pi_n, \mathbb{N} \} \), \( A_\alpha^n \) is supplied with the norm topology inherited from the topologically adjacent space of all poly \( R \)-homogeneous \( A_\Lambda \)-additive functionals.

In Note 2.10 [20] define \( A_{\Lambda,p,q} \) an use projections \( \pi_{s,p,t} \) for each \( s \neq p \in \mathbb{B} \). Theorems 2.11, 2.15 and Corollaries 2.13, 2.15.1 are transferrable on \( A_\Lambda \) with \( card(\Lambda) \geq \aleph_0 \) by imposing the condition of \((2\leq-1)\)-connectedness \( P_r(U) =: U_r \) for each \( r \geq 3 \) and every embedding of \( A_\infty \) into \( A_\Lambda \) for \( card(\Lambda) > \aleph_0 \) while corresponding \( A_r \subset A_\infty \) considering \( \pi_{s,p,t}(U) \) for each \( s = i_{2k}, \; p = i_{2k+1}, \; 0 \leq k \in \mathbb{Z} \). Then Definitions 2.12, 2.14 and Theorem 2.16, Notes 2.17, 3.1 are also accomplished for \( A_\Lambda \). Corollary 3.3 in this case follows from Theorem 3.6.2 [20].

As for \( A_\infty \) the algebra \( A_\Lambda \) with \( card(\Lambda) > \aleph_0 \) has any finite and even countable set of constants \( \{a_s, b_s\} \) in \( A_\Lambda \) such that \( z^* = \sum a_s z b_s \) for each \( z \in A_\Lambda \) could be written in as such series or sum. That is the algebraic antiautomorphism of order two \( \theta(z) := z^* \) with \( \theta \circ \theta = id \) is not internal in \( A_\Lambda \) and indeed \( z \) and \( z^* \) are algebraically independent variables in such infinite dimensional Cayley-Dickson algebra.

2.2.5. Proposition. Let \( U \) be an open subset in \( A_p \) and \( f : U \to A_p \) be a function on \( U \), where \( 2 \leq p \leq \infty \), let also \( A_\Lambda \) be the Cayley-Dickson algebra as in \$2.2.2 \) with \( card(\Lambda) \geq \aleph_0 \), then \( f \) is z-superdifferentiable if and only if there exists an open subset \( W \) in \( A_\Lambda \) and a z-superdifferentiable function \( g : W \to A_\Lambda \) such that its restriction on \( U \) coincides with \( f \), \( g|_U = f \).

Proof. In view of Theorem 2.2.3 there exists the embedding of \( A_p \) into \( A_\Lambda \). If \( g \) is z-superdifferentiable on \( W \), then from the definition it follows, that \( g|_V \) is z-superdifferentiable, where \( V = W \cap A_p \) and \( V \) is open in \( A_p \). Vice versa if \( f \) is z-superdifferentiable on \( U \), then it is locally z-analytic on \( U \) (see Theorems 2.15 and 3.10 [20]). For each \( z_0 \in U \) there exists a power series in \((z - z_0)\) converging in a ball \( B(A_p, z_0, r) \) with the centre \( z_0 \) and positive radius \( r > 0 \) the expansion coefficients of which belong to \( A_p \). Therefore, in the variable \((z - z_0)\) this series uniformly converges in \( B(A_\Lambda, z_0, r') \) for each \( 0 < r' < r \). The union of such balls \( B(A_\Lambda, z_0, r') \) is the open subset in \( A_\Lambda \) which we denote by \( W \). On each open intersection of each corresponding pair of such balls the functions given by such series coincide, that gives the z-superdifferentiable function \( g \) on \( W \) with \( g|_U = f \). Certainly there can be found others z-superdifferentiable extensions \( g \) of \( f \).

2.3. Theorem. Let \( U \) be a bounded open subset in \( A_\Lambda \) and let \( f : U \to A_\Lambda \) be a bounded continuous function. Then there exists a continuous function \( u(z) \) which is a solution of the equation

\[
(1) \quad (\partial u(z)/\partial z) = \hat{f}
\]

in \( U \), in particular, \((\partial u(z)/\partial z).1 = f(z)\).

Proof. Using embeddings of \( A_p \), \( 2 \leq p \leq \infty \), into \( A_\Lambda \) it is sufficient to prove this statement for arbitrary \( 2 \leq p \leq \in N \). Take \( 2 \leq p \leq N \) and \( A_p \) one-forms \( d\zeta \) expressible through \( d\zeta \) as \( \sum_{l=1}^{n(l)} P_{j,l,1} d\zeta P_{j,l,2} \) with fixed nonzero \( P_{j,l,1} \in A_p \), where \( l = 1, 2, 3, \ldots, 2^n \), \( k(l) \in \mathbb{N} \). Choose \( d\zeta \) to be satisfying conditions \( d\zeta_{2^n} \wedge \nu = \xi(z)((d^1 z \wedge d^2 z) \wedge d^3 z) \ldots \wedge d^{2^n} z \), \( d\zeta_{2^n} \wedge \nu = 0 \), where

\[
\nu = (\partial_{\zeta_{1}} Ln(\zeta_{1} - \zeta_{2}))(M_{1}^{1}))(\partial_{\zeta_{2}} Ln(\zeta_{2} - \zeta_{3}}))(M_{2}^{2}))(\partial_{\zeta_{m}} Ln(\zeta_{m} - \zeta_{m}))(M_{m}^{m})),
\]
For distributions it is possible to take them on a base space of cylindrical functions on the 2
plane \( \partial f \) in view of Theorem 2.1 applied to \( \hat{V} \). Then there exists \( d\zeta \) and \( \nu \) such that the continuous function

\[
(2) \quad u(z) := -(2\pi)^{1-2p} \int_U (\hat{f}(\zeta_1).d\zeta_2^p) \wedge \nu
\]
is a solution of equation (1). To demonstrate this take closed curves (paths) \( \gamma_j \) in \( U \) as in §2.1 and §2.2.4, for example, such that \( \zeta_j \in \gamma_j \) satisfy conditions: \( (\zeta_{2s-1} - \zeta_{2s}) = \eta_{2s-1} \) for each \( s = 1, ..., 2p-1, \eta_{2s-1} = r\eta_{2s-1}^r \) with \( 0 < r < 1 \), where \( \eta_{2s-1}^r \) and \( \eta_{2s} \) belong to the plane \( i_{2s-1}R + i_{2s}R, \eta_{2s} = \bar{\eta}_{2s-1} \) for each \( s = 1, ..., 2p-1, \bar{\eta}_1 = \eta_{2p} \). Hence \( d\eta_1 \wedge d\eta_1 = 0, d\eta_2 \wedge d\eta_2 = 0, \rangle \end{align*}
\[
(\nu) \eta_0^k d\nu = (d\nu_0) \eta_0^k \text{ for each } \nu
\]
for \( k = 1 \) and \( k = -1 \).

These variables are expressible as \( \zeta = \sum_{j=1}^{5(v)} P_{j,1} \zeta_j \) (see §§3.7 and 3.28 [19]). Therefore, there exists a subgroup of the group of all \( A_p \)-holomorphic diffeomorphisms of \( U \) preserving Conditions (ii) and the construction given above has natural generalizations with the help of such diffeomorphisms.

Suppose at first, that \( f \) is continuously differentiable in \( U \). Each \( \zeta_j \) is expressible in the form \( \zeta_j = \sum_i^l \langle b_j S_i \rangle \), where \( \langle b_j \rangle \in \mathfrak{R} \) are real variables, \( S_i \in \{i_0, i_1, ..., i_{2p-1} \} \), hence differentials \( (\partial f/\partial \zeta_j).d\zeta = \sum_i^l (\partial f/\partial z).S_i d\langle b_j \rangle + (\partial f/\partial \bar{z}).\bar{S}_i d\langle b_j \rangle \) are defined. Consider a fixed \( z_0 \in U \).

We take a \( C^{\infty} \)-function \( \chi \) on \( A_p \) such that \( \chi = 1 \) in a neighbourhood \( V \) of \( z_0 \), \( V \subset U \), \( \chi = 0 \) in a neighbourhood of \( A_p \setminus U \). Then \( u = u_1 + u_2 \), where

\[
u_1(z) := -(2\pi)^{1-2p} \int_U [\chi(\zeta_1+\bar{z}) (\hat{\chi}(\zeta_1, \bar{z}).d\zeta)] \wedge \nu,
\]
\[
u_2(z) := -(2\pi)^{1-2p} \int_U [(1 - \chi(\zeta_1)) (\hat{\chi}(\zeta_1, \bar{z}).d\zeta)] \wedge \nu.
\]

Then

\[
u(z) := -(2\pi)^{1-2p} \int_{A_p} [\chi(\zeta_1 + z) (\hat{\chi}(\zeta_1 + z).d\zeta)] \wedge \psi,
\]

\[
\psi := (\partial_\zeta Ln(\zeta_1 - z)) M^*_1 [(\partial_\zeta Ln(\zeta_2 - z)) M^*_2]...[(\partial_\zeta Ln(\zeta_m - z)) M^*_m].
\]

Since \( \partial_\zeta [\chi(\zeta_1 + z) \hat{\chi}(\zeta_1 + z).] \wedge \psi = 0 \) and \( (\partial/\partial \zeta_2) [\chi(\zeta_1 + z) \hat{\chi}(\zeta_1 + z).] \wedge \psi . d\zeta = \partial_\zeta [\chi(\zeta_1 + z) \hat{\chi}(\zeta_1 + z).] \wedge \psi \), then due to Equations (i, ii)

\[
(\frac{\partial u(z)}{\partial \bar{z}}) = -(2\pi)^{1-2p} \int_{A_p} \partial_{\zeta_2} [\chi(\zeta_1 + z) \hat{\chi}(\zeta_1 + z).] \wedge \psi.
\]

In view of Theorem 2.1 applied to \( \hat{\chi} \).S for each \( S \in \{i_0, i_1, ..., i_{2p-1} \} \) we have \( (\partial u_1/\partial \bar{z}) = \hat{f} \)
in \( V \), consequently, \( (\partial u_1/\partial \bar{z}) = \hat{f} \) in a neighbourhood of \( z_0 \).

Taking a sequence \( f^n \) of continuously differentiable functions uniformly converging to \( f \) on \( U \) we get the corresponding \( u^n \) such that in the sense of distributions \( (\partial u_1/\partial \bar{z}) = \lim_{n \to \infty} (\partial u^n/\partial \bar{z}) = \lim_n f^n = \hat{f} \). Consider the family of all embeddings \( \theta \) of \( A_p \) to \( A_\Lambda \), \( 2 \leq p < \infty \). There exists the generalized function (operator) \( \hat{f} \) on \( U \), hence there exists the restriction \( \hat{f}_{p,\theta} \) on \( U \cap \theta(A_p) \) for each \( (p, \theta) \). As the function this restriction evidently exists. For distributions it is possible to take them on a base space of cylindrical functions on the algebra of cylindrical subsets with bases in the projection \( \theta(A_p) \). Each rectifiable path \( \gamma \) is the limit of the uniformly converging net of paths \( \gamma_{p,\theta} \), since \( \gamma([0,1]) \) is compact. Therefore, such restriction exists in the sense of distributions.

Thus there exists the solution \( u_{p,\theta} \) of (1) given by (2) on \( U \cap \theta(A_p) \). The family of all \( (p, \theta) \) is directed: \( (p_1, \theta_1) \leq (p_2, \theta_2) \) if and only if \( p_1 \leq p_2 \) and \( \theta_1(A_{p_1}) \subset \theta_2(A_{p_2}) \). Since \( \hat{f}_{p,\theta} \)
converges to \( \hat{f} \) in the sense of distributions by the ultrafilter of the set \( \{(p, \theta)\} \), then \( u_{p,\theta} \) converges to the solution \( u \) on \( U \), since there exists \( \partial u(z)/\partial \bar{z} = \hat{f}(z) \).

**2.4. Theorem.** Let \( U \) be an open subset in \( A_p^n \), \( 2 \leq p \in \mathbb{N} \), \( n \in \mathbb{N} \). Then for every compact subset \( K \) in \( U \) and every multi-order \( k = (k_1, \ldots, k_n) \), there exists a constant \( C > 0 \) such that

\[
\max_{z \in K} |\partial^k f(z)| \leq C \int_U |f(z)| d\sigma_{2n}
\]

for each \( A_p \)-holomorphic function \( f \), where \( d\sigma_{2n} \) is the Lebesgue measure in \( A_p^n \).

**2.5. Corollary.** Let \( U \) be an open subset in \( A_p^n \), \( 2 \leq p \in \mathbb{N} \), \( n \in \mathbb{N} \), and let \( f_t \) be a sequence of \( A_p \)-holomorphic functions in \( U \) which is uniformly bounded on every compact subset of \( U \). Then there is a subsequence \( f_{t_k} \) converging uniformly on every compact subset of \( U \) to a limit in \( C_z^w(U, A_p) \).

Proofs of Theorem 2.4 and Corollary 2.5 follow from Theorem 2.1 above and Theorem 3.9 [19] (see also [20]) analogously to Theorem 1.1.13 and Corollary 1.1.14 [7].

**2.6. Definitions.** Let \( U \) be an open subset in \( A_p^n \) and \( f : U \rightarrow A_p^n \) be an \( A_p \)-holomorphic function, then the matrix: \( J_f(z) := (\partial f_j(z)/\partial z_k) \) is called the \( A_p \)-Jacobi matrix, where \( j = 1, \ldots, m \), \( k = 1, \ldots, n \). To this operator matrix there corresponds a real \( (2^m) \times (2^n) \)-matrix while \( 2 \leq p \in \mathbb{N} \) or operator from \( X^m \) into \( X^n \) of the underlying real Hilbert space \( X \) of \( A_p \) for infinite \( p = \Lambda \). Denote by \( \text{rank}_{\mathbb{R}}(J_f(z)) \) a rank of a real matrix or operator corresponding to \( J_f(z) \). This rank may be infinite. Then \( f \) is called regular at \( z \in U \), if \( \text{rank}_{\mathbb{R}}(J_f(z)) = 2^n \min(n,m) \) for finite \( p \) or \( \ker(f'(z)) = 0 \) and \( \text{Range}(f'(z)) \) is algebraically isomorphic with \( A_{\Lambda}^n \) such that \( \text{Range}(f'(z)) \cap A_{\Lambda}^n = A_{\Lambda}^n \) when \( m \leq n \) or \( \text{Range}(f'(z)) = X^n \) and \( \ker(f'(z)) \) is algebraically isomorphic with \( A_{\Lambda}^{m-n} \) while \( m > n \). If \( U \) and \( V \) are two open sets in \( A_p^n \), then a bijective surjective mapping \( f : U \rightarrow V \) is called \( A_p \)-biholomorphic if \( f \) and \( f^{-1} : V \rightarrow U \) are \( A_p \)-holomorphic.

**2.7. Proposition.** Let \( U \) and \( V \) be open subsets in \( A_p^n \) and \( A_p^m \) respectively. If \( f : U \rightarrow A_p^n \) and \( g : V \rightarrow A_p^m \) are \( A_p \)-holomorphic functions such that \( f(U) \subset V \), then \( g \circ f : U \rightarrow A_p^k \) is \( A_p \)-holomorphic and \( J_{g \circ f}(z) = J_g(f(z)) \circ (J_f(z), h) \) for each \( h \in A_p^n \).

Proof. In view of Definition 2.2 and Theorems 2.15 and 3.10 [20] \( (\partial g_j(f(z))/\partial z_l) \cdot \zeta = \sum_{j=1}^{k_1} \sum_{l=1}^{k_2} (\partial g_j(\xi)/\partial \xi_l) \cdot (\zeta = (f(z))/\partial z_l) \cdot h_l \), where \( h = (h_1, \ldots, h_n) \), \( h_l \in A_p \) for each \( l = 1, \ldots, n \), since \( f(U) \subset V \) and this is evident for \( A_p \)-polynomial functions and hence for locally converging series of \( A_p \)-holomorphic functions.

**2.8. Proposition.** Let \( U \) be a neighbourhood of \( z \in A_p^n \) and let \( f : U \rightarrow A_p^n \) be an \( A_p \)-holomorphic function. Then \( f \) is \( A_p \)-biholomorphic in some neighbourhood \( W \) of \( z \) if and only if \( f \) is regular at a point \( z \in U \).

Proof. From Proposition 2.7 it follows, that the condition of regularity of \( f \) on \( U \) is necessary. Prove the sufficiency. In view of Definition 2.2, Theorems 2.15 and 3.10 and Note 3.11 [20] an incerement of \( f \) can be written in the form \( f(z + \zeta) = f(z) + f'(z) \cdot \zeta + O(|\zeta|^2) \) for each \( \zeta \in A_p^n \) such that \( z + \zeta \in U \). Then there exists a neighborhood \( W \supset B(z, 2\epsilon, A_p^n) \) in which \( |g(z + \zeta)| \leq C|\zeta|^2 \), where \( 0 < \epsilon < (2C)^{-1} \), \( C \) is a positive constant, \( g := id - f \). Thus there exists an \( A_p \)-biholomorphic function \( w \) on an open neighbourhood \( W \) of \( z \) in \( U \) such that \( w \) is given by the series \( w = \sum_{k=1}^{\infty} g_k \), where \( g_{k+1} = g \circ g_k \) for each \( k \in \mathbb{N} \) and \( g_1 := g, g := id - f \), since for each \( \eta \in W \) there exists \( r > 0 \) such that \( B(\eta, r, A_p) \subset U \) and the series for \( w \) is convergent on \( B(\eta, r, A_p) \) with \( w(B(z, \epsilon, A_p^n)) \subset B(z, 2\epsilon, A_p^n) \).

Since \( f'(z) \) is the continuous epimorphism from \( A_p^n \) onto \( A_p^n \), then its graph is closed. On the other hand, \( f'(z) \) is bijective and there exists the \( \mathbb{R} \)-linear operator \( (f'(z))^{-1} \). The graph of it \( Gr(f'(z))^{-1} = \{(x,y) : x = f'(z) \cdot y ; x, y \in A_p^n \} \) is closed in \( A_p^n \otimes A_p^n \), since the graph of \( f'(z) \) is closed. In view of the closed mapping theorem (see 14.3.4 [23]) \( (f'(z))^{-1} \) is continuous. Thus the operator \( f'(z) \) is invertible. In view of the inverse mapping theorem
(see §X.7 [27]) there exists \( f^{-1} \) continuously (Frechét) differentiable on a neighborhood \( W \) of \( f(z) \). Since \( \partial f(z)/\partial z = 0 \), then \( \partial f^{-1}(z)/\partial z = 0 \) on \( W \).

For \( \eta \) in a sufficiently small neighborhood \( W \) of \( z \) there is satisfied the inequality \( \|1 - f'(z)^{-1}f'z(\eta)\| < 1 \), consequently, \( f'(\eta) \) is invertible for each \( \eta \in W \). The operator \( f'(\eta) \) is continuous by \( \eta \) on \( U \), hence there exists a neighborhood \( V \) of \( z \) such that \( f \) is regular on \( V \), since \( f'z(\eta) \) is \( R \)-homogeneous and \( A_p \)-additive and \( f'(z)(A_p^n) = A_p^n \). Hence \( f(V) \) is open in \( A_p^n \). Since \( w \) is the limit of the uniformly convergent series of \( A_p \)-holomorphic functions, then \( w \) is \( A_p \)-holomorphic on \( W \). From \( (id + h) \circ f = f \circ (id + h) = id \) on \( B(z, \epsilon, A_p^n) \) it follows, that \( f \) is \( A_p \)-biholomorphic on a neighborhood of \( z \).

2.9. Corollary. Let \( X \) be a subset in \( A_p^n \), \( 2 \leq p < \infty \) or \( p = \Lambda \), and \( k \in \{1, 2, ..., n - 1\} \), then the following conditions are equivalent:

(i) for each \( \zeta \in X \) there exists an \( A_p \)-biholomorphic map \( f = (f_1, ..., f_n) \) in some neighborhood \( U \) of \( \zeta \) such that \( f \) is regular on \( U \) and \( X \cap U = \{z \in U : f_{k+1}(z) = 0, ..., f_n(z) = 0\} \);

(ii) for each \( \zeta \in X \) there exists a neighborhood \( V \) of \( \zeta \) and a regular \( A_p \)-holomorphic map \( g : V \to A_p^{n-k} \) such that \( X \cap V = \{z \in V : g(z) = 0\} \).

Proof. The implication \((i) \Rightarrow (ii)\) follows by taking \( g = (f_{k+1}, ..., f_n) \) on \( V = U \). To prove implication \((ii) \Rightarrow (i)\) take \( \zeta \in X \), \( g \) and \( V \) as in \((i)\). There exists the \( R \)-linear operator \( G' \) corresponding to \( g'z(\zeta) \) from \( A_p^n \) onto \( A_p^{n-k} \). Thus there exists a right \( A_p \)-superlinear operator \( P \) from \( A_p^n \) onto \( A_p^k \) such that \( P \oplus g'z(\zeta) \) from \( A_p^n \) onto \( A_p^k \) is invertible. The \( A \)-holomorphic function \( f \) is invertible. The graph of \( P \oplus g'z(\zeta) \) is closed. In view of the closed mapping theorem (see 14.3.4 [23]) \( (P \oplus g'z(\zeta))^{-1} \) is continuous. Thus the operator \( (P \oplus g'z(\zeta))^{-1} \) is continuous. In view of the implicit mapping theorem and addition 3 to it (see §X.7 [27]) there exists \( (P \oplus g) \) continuously (Frechét) differentiable on a neighborhood \( W \) of \( (P \oplus g)(\zeta) \).

Put \( f(z) = (Pz, g(z)) \) for \( z \in V \). By Theorem 2.8 \( f \) is \( A_p^n \)-biholomorphic in some neighborhood \( U \subset V \). Then \( X \cap U = \{z \in U : f_{k+1}(z) = 0, ..., f_n(z) = 0\} \), since \( (f_{k+1}, ..., f_n) = g \) and \( X \cap U = \{z \in U : g(z) = 0\} \).

2.10. Definitions. Let \( U \) be an open subset in \( A_p^n \), \( 2 \leq p < \infty \) or \( p = \Lambda \). A subset \( X \) in \( U \) is called a \( A_p \)-submanifold of \( A_p^n \) if the equivalent conditions of Corollary 2.9 are satisfied. If in addition \( X \) is a closed subset in \( U \), then \( X \) is called a \( A_p \)-submanifold of \( U \). This definition is the particular case of the following general definition.

An \( A_p \)-holomorphic manifold of \( A_p \)-dimension \( n \) is a real \( 2p^n \)-dimensional or \( \text{card}(\Lambda) \)-dimensional \( C^\infty \)-manifold \( X \) together with a family \( \{(U_j, \phi_j) : j \in \Psi\} \) of charts such that:

(i) each \( U_j \) is an open subset in \( X \) and \( U_j \subset U_j \); \( X \); where \( \Psi \) is a set;

(ii) for each \( j \in \Psi \) a mapping \( \phi_j : U_j \to V_j \) is a homeomorphism on an open subset \( V_j \) in \( A_p^n \);

(iii) for each \( j, l \in \Psi \) a connection mapping \( \phi_j \circ \phi_l^{-1} \) is an \( A_p \)-biholomorphic map (see §2.6) from \( \phi_l(U_j \cap U_l) \) onto \( \phi_j(U_j \cap U_l) \). Such system is called an \( A_p \)-holomorphic atlas \( At(X) := \{(U_j, \phi_j) : j \in \Psi\} \). Each chart \( (U_j, \phi_j) \) provides a system of \( A_p \)-holomorphic coordinates induced from \( A_p^n \). For short we shall write \( A_p \)-manifold instead of \( A_p \)-holomorphic manifold and \( A_p \)-atlas instead of \( A_p \)-holomorphic atlas if other will not be specified.

For two \( A_p \)-manifolds \( X \) and \( Y \) with atlases \( At(X) := \{(U_j, \phi_j) : j \in \Psi_X\} \) and \( At(Y) := \{(V_l, \psi_l) : l \in \Psi_Y\} \) a function \( f : X \to Y \) is called \( A_p \)-holomorphic if \( \psi_l \circ f \circ \phi_j^{-1} \) is \( A_p \)-holomorphic on \( \phi_j(U_j \cap f^{-1}(W_l)) \). If \( f : X \to Y \) is an \( A_p \)-biholomorphic epimorphism, then \( X \) and \( Y \) are called \( A_p \)-biholomorphically equivalent.

A subset \( Z \) of an \( A_p \)-manifold \( X \) is called an \( A_p \)-submanifold, if \( \phi_j(U_j \cap Z) \) is an \( A_p \)-submanifold in \( A_p^n \) for each chart \( (U_j, \phi_j) \). If additionally \( Z \) is closed in \( X \), then \( Z \) is called a closed \( A_p \)-submanifold.
2.11. Theorem. Let $n \geq 2$, $f_1, ..., f_n \in C^1_{0(\zeta, \bar{\zeta})}(A^n_p, A_p)$ with $2 \leq p < \infty$ or $p = \Lambda$ be a family of continuously $A_p \ (z, \bar{z})$-superdifferentiable functions satisfying compatibility conditions:

(i) $\partial f_j / \partial \bar{z}_k = \partial f_k / \partial \bar{z}_j$ for each $j, k = 1, ..., n$,
where $C^1_{0(\zeta, \bar{\zeta})}(A^n_p, A_p)$ is the subspace of $C^1_{(\zeta, \bar{\zeta})}(A^n_p, A_p)$ of functions with closed bounded support. Then there exists $u \in C^1_{0(\zeta, \bar{\zeta})}(A^n_p, A_p)$ satisfying the following $\bar{\partial}$-equation:

$\partial u / \partial \bar{z}_j = \hat{f}_j, \ j = 1, ..., n$

in particular, $(\partial u / \partial \bar{z}_j). 1 = f_j$.

Proof. Using the beginning and the end of the proof of Theorem 2.3 we reduce the proof of Theorem 2.11 to the case of finite $p$ mentioning, that the intersection $A \cap \theta(A_p)^n$ of a closed bounded subset $A$ in $A^n_p$ for finite $p$ is compact. We put

$$(iii) \quad u(z) := -(2\pi)^{-2p} \int_{\theta(A_p)} \{\hat{f}_1(z_1, z_2, ..., z_n) d\bar{z}_2 \wedge \eta\},$$
where

$$\eta := (\partial_1 \ln(\zeta_1 - \zeta_2))M_1^* \{\partial_2 \ln(\zeta_2 - \zeta_3))M_2^* \} ... \{\partial_m \ln(\zeta_m - z))M_m^* \}$$

$m = 2^p - 1$ (see §2.3). By changing of variables we get

$$u(z) := -(2\pi)^{-2p} \int_{A_p} \{\hat{f}_1(z_1 + \zeta_1, z_2, ..., z_n) d\bar{z}_2 \wedge \psi\},$$
where

$$\psi := (\partial_1 \ln(\zeta_1 - \zeta_2))M_1^* \{\partial_2 \ln(\zeta_2 - \zeta_3))M_2^* \} ... \{\partial_m \ln(\zeta_m - z))M_m^* \}$$

$m = 2^p - 1$. Therefore, $u \in C^1_{(\zeta, \bar{\zeta})}(A^n_p, A_p)$. Due to Theorem 2.3 $\partial u / \partial \bar{z}_1 = \hat{f}_1$ in $A^n_p$. In view of Theorem 2.1 and the condition $\partial f_1 / \partial \bar{z}_k = \partial f_k / \partial \bar{z}_1$ the following equality is satisfied

$$\hat{f}_k(z) = -(2\pi)^{-2p} \int_{A_p} \{\hat{f}_1(z_1, z_2, ..., z_n) d\bar{z}_2 \wedge \psi\},$$

hence $\partial u / \partial \bar{z}_k = \hat{f}_k$ for $k = 2, ..., n$, that is, $u$ satisfies equations (ii). From this it follows, that $u$ is $A_p$-holomorphic in $A^n_p \setminus (\text{supp}(f_1) \cup ... \cup \text{supp}(f_n))$. In view of formula (iii) it follows, that there exists $0 < r < \infty$ such that

(iv) $u(z) = 0$ for each $z \in A^n_p$ with $|z_2| + ... + |z_n| > r$. From $\partial u / \partial \bar{z}_1 = \hat{f}_1$ it follows, that $\partial u / \partial \bar{z}_1 = 0$ in $A^n_p \setminus \text{supp}(f_1)$. Consequently, there exists $0 < R < \infty$ such that $u$ may differ from 0 on $A^n_p \setminus B(A^n_p, 0, R)$ only on an $A_p$ constant (see Theorem 3.28 and Note 3.11 in [20]). Together with (iv) this gives, that $u(z) = 0$ on $A^n_p \setminus B(A^n_p, 0, \max(R, r))$.

2.12. Theorem. Let $U$ be an open subset in $A^n_p$, where $n \geq 2$, $2 \leq p < \infty$ or $p = \Lambda$. Suppose $K$ is a bounded closed subset in $U$ such that $U \setminus K$ is connected. Then for every $A_p$-holomorphic function $h$ on $U \setminus K$ there exists a function $H$ $A_p$-holomorphic in $U$ such that $H = h$ in $U \setminus K$.

Proof. Take any infinite $(\zeta, \bar{\zeta})$-differentiable function $\chi$ on $U$ with bounded closed support such that $\chi|_V = 1$ on some (open) neighbourhood $V$ of $K$. Then consider a family of functions $f_j$ such that $\hat{f}_j (z, \bar{z}) S = -\{(\partial \chi / \partial \bar{z}) S\} h$ in $U \setminus K$ and $f_j = 0$ outside $U \setminus K$ for each $S$ in the set of generators of $A_p$, where $j = 1, ..., n, f_j(z) = \hat{f}_j(z). 1$. Therefore, conditions of Theorem 2.11 are satisfied and it gives a function $u \in C^1_{0(\zeta, \bar{\zeta})}(A^n_p, A_p)$ such that $\partial u / \partial \bar{z}_j = \hat{f}_j$ for each $j = 1, ..., n$. A desired function $H$ can be defined by the formula $H := (1 - \chi) h - u$ such that $H$ is $A_p$-holomorphic in $U$. Since $\chi$ has a bounded closed support, then there exists an unbounded connected subset $W$ in $A^n_p \setminus \text{supp}(\chi)$. Therefore,
$u|_W = 0$, consequently, $H|_{U \cap W} = h|_{U \cap W}$. From $(U \setminus K) \cap W \neq \emptyset$ and connectedness of $U \setminus K$ it follows, that $H|_{U \setminus K} = h|_{U \setminus K}$.

2.13. **Remark.** In the particular case of a singleton $K = \{ z \}$ Theorem 2.12 gives nonexistence of isolated singularities, that is, each $\mathcal{A}_p$-holomorphic function in $U \setminus \{ z \}$ for $U$ open in $\mathcal{A}_p^n$ with $n \geq 2$ can be $\mathcal{A}_p$-holomorphically extended to $z$. Theorem 2.12 is the $\mathcal{A}_p$-analog of the Hartog’s theorem for $\mathbb{C}^n$.

2.14. **Corollary.** Let $U$ be an open connected subset in $\mathcal{A}_p^n$, $2 \leq p < \infty$ or $p = \Lambda$ and $n \geq 2$. Suppose that $f$ is a right superlinearly $\mathcal{A}_p$-superdifferentiable function $f : U \to \mathcal{A}_p$ and $N(f) := \{ z \in U : f(z) = 0 \}$, then

(i) $U \setminus N(f)$ is connected,

(ii) $N(f)$ is not bounded closed.

**Proof.** Reduce the proof of this corollary to the case of finite $p$ using the beginning and the end of the proof of Theorem 2.3. Since if statements (i, ii) are true in the projection from $\mathcal{A}_p$ on $\theta(\mathcal{A}_p)$, then they are true for $\mathcal{A}_p$. (i). Write $f$ in the form $f = \sum_{i=1}^{2^p-1} i_1 g_1$, where $g_1 := \bar{f}_{2^1-1} + i_2 \bar{f}_{2^2} f_{2^1}, f = \sum_{i=1}^{2^p-1} z_1 f_s$, $f_s$ are real-valued functions, $\{i_0, \ldots, i_{2^p-1}\}$ is the set of generators of the Cayley-Dickson algebra $\mathcal{A}_p$. In view of Proposition 2.3 and Corollary 2.5.1 [20] each function $g_1$ is holomorphic in complex variables $y_k$, $k = 1, \ldots, 2^p-1$, where $z = \sum_{i=1}^{2^p-1} i_2 \bar{y}_1 y_1 + i_2 \bar{y}_2 f_2 f_{2^1}, f_2, \ldots, x_{2^p} \in \mathbb{R}$, $z \in \mathcal{A}_p$.

Therefore, $N(f) = \cap_{i=1}^{2^p-1} N(g_i)$, consequently, $U \setminus N(f) = \bigcup_{i=1}^{2^p-1} (U \setminus N(g_i))$. Then from Corollary 1.2.4 [7] for complex holomorphic functions (i) follows.

(ii). Suppose that $N(f)$ is bounded closed (compact for finite $p$). In view of (i) and Theorem 2.12 the function $1/f$ can be $\mathcal{A}_p$-holomorphically extended on $N(f)$. This is the contradiction, since $f = 0$ on $N(f)$.

2.14.1. **Note.** Corollary 2.14 is not true for arbitrary $\mathcal{A}_p$-holomorphic functions, for example, $f(1, z) = f(1, z) f_2 (2 z)$ on $B(\mathcal{A}_p^2, 0, 2)$, where $f_1 (1, z) := -z/2 (\sum_{i=1}^{2^p-1} i_1 z_1 i_1 - 1) / (2^p - 2) - r_1, f_2 (1, z) := -z^2 (\sum_{i=1}^{2^p-1} i_1 z_1 i_1 - 1) / (2^p - 2) - r_2$ for finite $2 \leq p$, $0 < r_1, 0 < r_2, r_1^2 + r_2^2 < 4$.

2.15. **Theorem.** Let $U$ be an open subset in $\mathcal{A}_p^n$, $2 \leq p < \infty$ or $p = \Lambda$, $f_1, \ldots, f_n$ be infinite Frechét differentiable (by real variables) functions on $U$ and suppose $(z, \bar{z})$-superdifferentiable that Conditions 2.11.(i) are satisfied in $U$. Then for each open bounded polytor $P = P_1 \times \cdots \times P_n$ such that $cl(P)$ is a subset in $U$, there exists a function $u$ infinite differentiable (by real variables) on $P$ and satisfying Conditions 2.11.(ii) on $P$.

**Proof.** Using the beginning and the end of the proof of Theorem 2.3 reduce the proof of this theorem to finite $p$. Suppose that the theorem is true for $f_{m+1} = \cdots = f_n = 0$ on $U$. The case $m = 0$ is trivial. Assume that the theorem is proved for $m - 1$. Consider $U = U_1 \times \cdots \times U_n$ and $U'' = U_1' \times \cdots \times U_n'$ open polytors in $\mathcal{A}_p^n$ such that $P \subset cl(P) \subset U'' \subset cl(U'') \subset U' \subset cl(U') \subset U$. Take an infinite differentiable (by real variables) function $\chi$ on $U''$ with compact support such that $\chi|_{U''} = 1$, $\chi = 0$ in a neighbourhood of $\mathcal{A}_p \setminus U''$. There exists a function

$$\eta(z) := -(2\pi)^{-1} \int_{U''} \left[ \chi(\zeta) (f_m (1, z, \ldots, m-1, \zeta_1, m+1 z, \ldots, n), d\bar{z}_{2m}) \right] \land \nu,$$

where a differential form $\nu$ is given in §2.3 with $\zeta_1, \zeta_2, \ldots, \zeta_{2^p-1} \in U''$ and $m z$ here for $\nu$ instead of $z$ in §2.3. By changing of variables as in §2.3 we get

$$\eta(z) := -(2\pi)^{-1} \int_{\mathcal{A}_p} \left[ \chi(\zeta_1 + z) (f_m (1, z, \ldots, m-1, \zeta_1 + m z, m+1 z, \ldots, n z), d\bar{z}_{2m}) \right] \land \psi,$$

where the differential form $\psi$ is the same as in §2.11. Consequently, $\partial \eta / \partial \bar{z}_m = f_m$ in $U'$. In view of Conditions 2.11(i) and differentiating under the sign of the integral, since the support

11
of $\chi$ is compact, we get $\partial \eta(z)/\partial \bar{z} = \hat{f}_j = 0$ on $U'$ for $j = m+1, ..., n$, since $f_j = 0$, $\hat{f}_j, 1 = f_j$, $\hat{f}_j$ is the partial (super)derivative of some function $\xi_j$ by $z$. Thus functions $g_j := f_j - \partial \eta/\partial \bar{z}$ for $j = 1, ..., n$ fulfil the compatibility conditions 2.11(i), consequently, $g_m, ..., g_n = 0$ in $U''$. And inevitably by the induction hypothesis there exists a function $v \in C^\infty(P, \mathcal{A}_p)$ such that $\partial v/\partial \bar{z}_j = g_j$ in $P$ for which $u = v + \eta$ is the required solution.

2.16. Definition. Let $W$ be an open subset in $\mathcal{A}_p^n$, $2 \leq p < \infty$ or $p = \Lambda$ and for each open subsets $U$ and $V$ in $\mathcal{A}_p^n$ such that

(i) $\emptyset \neq U \subseteq V \cap W \neq V$

(ii) $V$ is connected

there exists an $\mathcal{A}_p$-holomorphic (right superlinearly superdifferentiable, in short RSS, correspondingly) function $f$ in $W$ such that there does not exist any $\mathcal{A}_p$-holomorphic (RSS) function $g$ in $V$ such that $g = f$ in $U$. Then $W$ is called a domain of $\mathcal{A}_p$ (RSS, respectively) holomorphy. Sets of $\mathcal{A}_p$-holomorphic (RSS) functions in $W$ are denoted by $\mathcal{H}(W)$ ($\mathcal{H}_{RSS}(W)$ respectively).

2.17. Definition. Suppose that $W$ is an open subset in $\mathcal{A}_p^n$, $2 \leq p < \infty$ or $p = \Lambda$ and $K$ is a closed bounded subset of $W$, then

(i) $\hat{K}_W^\mathcal{H} := \{z \in W : |f(z)| \leq \sup_{\zeta \in K} \|\hat{f}(\zeta)\| \text{ for each } f \in \mathcal{H}(W)\};$

(ii) $\hat{K}_W^{\mathcal{H}_{RSS}} := \{z \in W : |f(z)| \leq \sup_{\zeta \in K} |f(\zeta)| \text{ for each } f \in \mathcal{H}_{RSS}(W)\};$

these sets are called the $\mathcal{H}(W)$-convex hull of $K$ and the $\mathcal{H}_{RSS}(W)$-convex hull of $K$ respectively, where $\|\hat{f}(\zeta)\| := \sup_{\eta \in \hat{A}_p^n}|\hat{f}(\eta)|$. If $K = \hat{K}_W^\mathcal{H}$ or $K = \hat{K}_W^{\mathcal{H}_{RSS}}$, then $K$ is called $\mathcal{H}(W)$-convex or $\mathcal{H}_{RSS}(W)$-convex correspondingly.

2.18. Proposition. For each closed bounded subset $K$ in $\mathcal{A}_p^n$, $2 \leq p < \infty$ or $p = \Lambda$, the $\mathcal{H}(\mathcal{A}_p^n)$-hull and $\mathcal{H}_{RSS}(\mathcal{A}_p^n)$-hull of $K$ are contained in the $\mathcal{R}$-convex hull of $K$.

Proof. Reduce the proof to the case of finite $p$ using §2.3.

I. Consider at first the $\mathcal{H}(\mathcal{A}_p^n)$-hull of $K$. Each $z \in \mathcal{A}_p^n$ can be written in the form $z = (z^1, ..., z^n), z^i \in \mathcal{A}_p, z^i = \sum_{l=1}^{2^n} x_{l,j} S_l$, where $x_{l,j} = x_{l, j}(z) \in \mathcal{R}, S_l = i_{l-1}$. If $w \in \mathcal{A}_p^n, w \notin \text{cor}(K)$, then there are $y_1, ..., y_{2^n} \in \mathcal{R}$ such that $\sum_{j=1}^{2^n} x_{l,j}(w) y_{2^n(j-1)+l} = 0$, but $\sum_{j=1}^{2^n} x_{l,j}(w) y_{2^n(j-1)+l} < 0$ if $z \in K$, where $\text{cor}(K) := \{z \in \mathcal{A}_p^n : \text{there are } a_1, ..., a_n \in \mathcal{R} \text{ and } v_1, ..., v_n \in K \text{ such that } z = a_1 v_1 + \ldots + a_n v_n\}$ denotes a $\mathcal{R}$-convex hull of $K$ in $\mathcal{A}_p^n$. Put $\zeta_j = \sum_{l,j} y_{2^n(j-1)+l} S_l$, then $f(z) := \exp(\sum_{j=1}^{2^n} y_{2^n(j-1)+j} \zeta_j)$ is the $\mathcal{A}_p$-holomorphic function in $\mathcal{A}_p^n$ such that $|f(z)| < 1$ for each $z \in K$ and $|f(w)| = 1$ for the marked point $w$ above (see Corollary 3.3 [19]), since $v^2 = -1$ for each $v > 0$. From $|\hat{f}(\zeta)| \leq |f(\zeta)|$ the first statement follows.

II. Consider now the $\mathcal{H}_{RSS}(\mathcal{A}_p^n)$-hull of $K$. Each $f \in \mathcal{H}_{RSS}(W)$ has the form $f = \sum_{i=1}^{2^n} g_i y_i$, where each function $g_i$ is holomorphic in complex variables $y_k$ (see §2.14).

The set $K$ has projection $K_k$ on the complex subspaces $\mathcal{C}^n$ corresponding to variables $y_k, ..., y_k$. Therefore, $(\hat{K}_{\mathcal{A}_p})_k \subset \hat{K}_{\mathcal{C}^n}$ for each $k$, where $\hat{K}_{\mathcal{C}^n}$ denotes the complex holomorphic hull of $K_k$ in $\mathcal{C}^n$. In view of Proposition 1.3.3 [7] $\hat{K}_{\mathcal{C}^n} \subset \text{cor}(K_k)$, hence $\hat{K}_{\mathcal{A}_p} \subset \text{cor}(K)$.  

2.18.1. Note. Due to Proposition 2.18 above Corollary 1.3.4 [7] can be transferred on $\mathcal{H}$ and $\mathcal{H}_{RSS}$ for $\mathcal{A}_p^n$ instead of $\mathcal{C}^n$. Also $\mathcal{A}_p$-versions of Theorems 1.3.5, 7, 11, Corollaries 1.3.6, 8, 9, 10, 13 and Definition 1.3.12 are true in the $\mathcal{H}_{RSS}$-class of functions instead of complex holomorphic functions.
3 Integral representations of functions of Cayley-Dickson variables

3.1. Definitions and Notations. Consider an $A_p$-valued function on $A_p^n$, $2 \leq p < \infty$ or $p = \Lambda$ such that

(i) $(\zeta, \zeta) = ae$ with $a \geq 0$ and $(\zeta, \zeta) = 0$ if and only if $\zeta = 0$,
(ii) $(\zeta, z + \xi) = (\zeta, z) + (\zeta, \xi)$,
(iii) $(\zeta + \xi, z) = (\zeta, z) + (\xi, z)$,
(iv) $(\alpha \zeta, z) = \alpha (\zeta, z) = (\zeta, \alpha z)$ for each $\alpha \in \mathbb{R}$ and $(\zeta \alpha, \zeta) = \bar{\alpha} (\zeta, \zeta)$ for each $\alpha \in A_p$,
(v) $(\zeta, z^i) = (z, \zeta)$ for each $\zeta, \xi$ and $z \in A_p^n$, $n \in \mathbb{N}$. Then this function is called the scalar product in $A_p^n$. The corresponding norm is:

(vi) $|\zeta| = \{(\zeta, \zeta)\}^{1/2}$. In particular, it is possible to take the canonical scalar product:

(vii) $< \zeta, \zeta > : (\zeta, z) = \sum_{i=1}^l \zeta^i z_i$, where $z = (z^1, ..., z^n)$, $l \in A_p$.

Consider differential forms on $A_p$:

(1) $\phi_{p,0}(z) := d\zeta \wedge d\bar{\zeta}$, $\phi'_{p,0}(z) := d\zeta \bar{\zeta}$,
$\phi_{p,k}(z) := (i_{2k}(d\zeta \bar{\zeta})) \wedge (i_{2k}(d\bar{\zeta} \zeta))$, $\phi'_{p,k}(z) := (i_{2k}(\bar{\zeta} \zeta)) \wedge (i_{2k}(\zeta \bar{\zeta}))$, for each $k = 0, 2p-1, 1$,

(2) $w_{2p}(z) := C_p\{(\phi_{p,0}(z) \wedge \phi_{p,1}(z) \wedge ... \wedge \phi_{p,2p-1}(z)) \}_{q_0(2p-1)}$,
where $C_p = \text{const} \neq 0$;

(3) $w_{2p,k}(z) := \{(\phi_{p,0}(z) \wedge \phi_{p,1}(z) \wedge ... \wedge \phi_{p,k-1}(z) \wedge \phi'_{p,k}(z) \wedge \phi_{p,k+1}(z) \wedge \phi_{p,2p-1}(z)) \}_{q_0(2p-1)}$
for each $k = 0, 2p-1, 1$,

(4) $\tilde{\zeta}, \tilde{\zeta}$ in the $\zeta$ and $z$-representations respectively: $\tilde{\zeta} = (2p-2)^{-1}\{z + \sum_{a \in \mathbb{N}} s(z^a)\}$ for each $2 \leq p \in \mathbb{N}$.

With the help of them construct differential forms on $A_p^n$:

(10) $\theta_{s}(\zeta) := C'_p |\zeta - z|^{-2p} \sum_{s=1}^{n} \sum_{q=0}^{2p-1} \{w_{2p}(1\zeta) \wedge ... \wedge w_{2p}(s-1\zeta) \wedge w_{2p}(s\zeta) \wedge w_{2p}(s+1\zeta) \wedge ... \wedge w_{2p}(n\zeta)\}_{q_0(n)}$.

(11) $\tilde{\theta}(\zeta, z) := C''_p |\zeta - z|^{-2p} \sum_{s=1}^{n} \sum_{q=0}^{2p-1} \{\tilde{w}_{2p}(1\zeta, 1z) \wedge ...$
\[ \wedge \hat{w}_2^{(s-1, s-1, z)} \wedge \hat{w}_2^{(\sigma, z)} \wedge \hat{w}_2^{(s+1, \zeta, s+1, z)} \wedge ... \wedge \hat{w}_2^{(n, n, z)} \}_{q_0(n)}; \]

(12)  \[ \hat{\theta}(\zeta, z) := C'_p \vert \zeta - z \vert^{-2p-1} \sum_{s=1}^{n} \sum_{q=0}^{2p-1-1} \{ \hat{w}_2^{(1, 1, z)} \wedge ... \]

\[ \wedge \hat{w}_2^{(s-1, s-1, z)} \wedge \hat{w}_2^{(\sigma, s, z)} \wedge \hat{w}_2^{(s+1, \zeta, s+1, z)} \wedge ... \wedge \hat{w}_2^{(n, n, z)} \}_{q_0(n)}, \]

where \( C'_p := (2^n n!)^2/2^{p-1} p! ; \) \( \vert \zeta - z \vert^2 \) is considered in the \((\zeta - z, \zeta - \bar{z})\)-representation:

\[ \vert s \zeta - \bar{s}z \vert^2 = (s \zeta - s \bar{z})(s \bar{z} - s \bar{z}), \]

\( \vert \zeta - z \vert^2 = \sum_{s=1}^{n} \vert s \zeta - s \bar{z} \vert^2, \) and \( z \in A^n_p. \) If \( U \) is an open subset in \( A^n_p \) and \( f \) is a bounded \( A_p \)-differential form on \( U \), then by the definition:

(13)  \[ (B_U(f))(z) := \int_{\zeta \in U} f(\zeta) \wedge \hat{\theta}(\zeta, z) \]

for each \( z \in A^n_p. \) If in addition \( U \) is with a continuous piecewise \( C^1 \)-boundary (by the corresponding real variables) and \( f \) is a bounded differential form on \( \partial U \), then by the definition:

(14)  \[ (B_{\partial U}(f))(z) := \int_{\zeta \in \partial U} f(\zeta) \wedge \hat{\theta}(\zeta, z) \]

for each \( z \in A^n_p. \)

3.2. Theorem. Let \( U \) be an open subset in \( A^n_p, \) \( 2 \leq p \in \mathbb{N}, \) with piecewise \( C^1 \)-boundary \( \partial U. \) Suppose that \( f \) is a continuous function on \( \text{cl}(U) \) and \( \partial f \) is continuous on \( U \) in the sense of distributions and has a continuous extension on \( \text{cl}(U) \).

Then

(1)  \[ f = B_{\partial U} f - B_U \hat{\partial} f \text{ on } U, \]

where \( B_U \) and \( B_{\partial U} \) are the \( A_p \)-integral operators given by Equations 3.1.(13, 14).

Proof. Write the variable \( z \) in the form \( z = \sum_{l=0}^{p-1} i_2 l \alpha_l, \) where \( \alpha_l \in C_l := \mathbb{R} \oplus i_2 i_2 \mathbb{R}, \) \( i_2 \alpha_l = i_2 x_l + i_2 y_l, \) where \( x_l, y_l \in \mathbb{R}. \) Then

(1) \[ \alpha_0 i_2 k = i_2 \alpha_0 \] for each \( k \neq 0, \)

(2) \[ i_2 (d_2 z_2 k) = (\sum_{l \neq k} i_2 d_2 \alpha_l) - i_2 d_2 \alpha_k - d_2 \alpha_k, \]

(3) \[ (i_2 d_2 \alpha_l) \wedge d_2 \alpha_l = -d_2 \alpha_l \wedge (i_2 d_2 \alpha_l) \] for each \( l > 0, \)

(4) \[ (i_2 d_2 \alpha_l) \wedge (i_2 d_2 \alpha_q) = (i_2 d_2 \alpha_q) \wedge (i_2 d_2 \alpha_l) \] for each \( l \neq q \) with \( l > 0 \) and \( q > 0, \)

(5) \[ (i_2 d_2 \alpha_l) \wedge (i_2 d_2 \alpha_k) = 0 \] for each \( l > 0, \)

(6) \[ d_2 \alpha_0 \wedge d_2 \alpha_0 = -d_2 \alpha_0 \wedge d_2 \alpha_0 = -i_2 i_2 d_2 x_0 \wedge d_2 y_0, \]

(7) \[ i_2 d_2 \alpha_l \wedge (i_2 d_2 \alpha_k) = 2 i_2 \alpha_l i_2 \alpha_k d_2 x_1 \wedge d_2 y_1, \]

for each \( l > 0. \)

From Equations (1 - 7) and \( d \bar{z} = d \bar{\alpha}_0 - \sum_{l>0} i_2 d_2 \alpha_l \) it follows, that

(8) \[ \phi_{p,0}(z) = (d_2 \alpha_0 - d_2 \alpha_0) \wedge (\sum_{q>0} i_2 d_2 \alpha_q) + \sum_{l>0} \sum_{q>0} \sum_{l \neq k} i_2 d_2 \alpha_l \wedge (i_2 d_2 \alpha_k), \]

(9) \[ \phi_{p,k}(z) = (d_2 \alpha_0 \wedge d_2 \alpha_0) - (d_2 \alpha_k \wedge d_2 \alpha_k) + (2 i_2 d_2 \alpha_k \wedge (\sum_{l \neq k} i_2 d_2 \alpha_l)) - \sum_{l>0, l \neq k} \sum_{q>0, q \neq k} (i_2 d_2 \alpha_l) \wedge (i_2 d_2 \alpha_q) \]

for each \( k > 0. \) The differential form \( w_2 \) is of degree \( 2^p \) in real coordinates \( x_0, y_0, ..., x_{2p-1}, y_{2p-1}, \) hence it may contain only the multiplier \( d_2 x_0 \wedge d_2 y_0 \) or may contain only \( d_2 x_0 \wedge d_2 y_0, \) hence all terms in \( w_2 \) arising from the term \( (d_2 \alpha_0 - d_2 \alpha_0) \wedge (\sum_{q>0} i_2 d_2 \alpha_q) \) in \( \phi_{p,0}(z) \) cancel, since \( \phi_{p,k}(z) \) contains \( d_2 \alpha_0 \wedge d_2 \alpha_0 \) for each \( k > 0. \) Then from (3 - 5) it follows, that all terms arising from the term \((2 i_2 d_2 \alpha_k \wedge (\sum_{l \neq k} i_2 d_2 \alpha_l))\) in \( \phi_{p,k}(z) \) for \( k > 0 \) cancel in \( w_2. \) Thus for a choice of the multiplier \( d_2 \alpha_0 \wedge d_2 \alpha_0 \) in \( w_2 \) there are \((2^{p-1} - 1) \) possibilities among \( \phi_{p,q}(z) \) with \( q = 1, ..., 2^{p-1} - 1 \) in the graded external product. After a choice of \( d_2 \alpha_0 \wedge d_2 \alpha_0 \) for some \( q > 0 \) it remains \((2^p - 2)(2^{p-3})/2 \) variants for a choice of the multiplier \( d_2 \alpha_1 \wedge d_2 \alpha_1 = (i_2 d_2 \alpha_1) \wedge (i_2 d_2 \alpha_1). \) Then by induction after choices of the multipliers \((i_2 d_2 \alpha_v) \wedge (i_2 d_2 \alpha_v) = d_2 \alpha_v \wedge d_2 \alpha_v \) for \( v = 0, 1, ..., q - 1 \) with \( q > 2 \) it remains
\((2^p - 2q)(2^p - 2q - 1)/2\) variants for choices of the multiplier \((i_2q d\alpha_q) \wedge (i_2q d\alpha_q)\). Thus
\[(10) \quad w_{2^p} = (-1)^{2^{p-1}-2} C_p[(2^p - 2)!(2^p - 1)2^{-(2^p-1)-1}\{(d\alpha_0 \wedge d\bar{\alpha}_0) \wedge ((i_2d\alpha_1) \wedge (i_2d\alpha_1)) \wedge ... \wedge ((i_2d\alpha_2d\alpha_{2p-1}) \wedge (i_2d\alpha_2d\alpha_{2p-1}))\}]_{q_0(2^{p-1})}
= (C_p[(2^p - 2)!(2^p - 1)]d\alpha_0 \wedge d\bar{\alpha}_0 \wedge dx_1 \wedge dy_1 \wedge ... \wedge dx_{2p-1} \wedge dy_{2p-1},
\]
since \((i_0i_1)(i_2i_3) = i_1^2 = -1\), \{\((i_0i_1)(i_2i_3)\ldots(i_{2p-1}i_{2p-1})\}\}_{q_0(2^{p-1})} = -1. Hence \(w_{2^p}\) is the volume element on \(A_p\) equal to the Lebesgue measure \(\mu\) on the underlying Euclidean space \(\mathbb{R}^{2^p}\) such that \(\mu([0, 1]^{2^p}) = 1\), since \(C_p = ([(2^p - 2)!2(2^p - 1)-(1)])^{-1}\).

The differential form \(\tilde{\theta}(\zeta, z)\) has the decomposition

\[(11) \quad \tilde{\theta}(\zeta, z) = \sum_{q=0}^{2^p - 1} \gamma_q(\zeta, z),\]

where \(\gamma_q(\zeta, z)\) is the \(A_p\)-differential form with all terms of degree \(2^p n - q - 1\) by \(\zeta\) and \(\bar{\zeta}\) and their multiples on \(A_p\) constants and of degree \(q\) by \(z\) and \(\bar{z}\) and their multiples on \(A_p\) constants. The differential form \(f(\zeta)\) has the decomposition

\[(12) \quad f(\zeta) = \sum_{r=0}^{m} f_r(\zeta),\]

where \(m = \deg(f)\), \(f_r(\zeta)\) is with all terms of degree \(r\) by \(\zeta\) and \(\bar{\zeta}\) and their multiples on \(A_p\) constants. Then \(f_r \wedge \gamma_q = 0\), when \(r > q + 1\). By the definition of integration \(\int_{\zeta \in U} f_r(\zeta) \wedge \gamma_q(\zeta, z) = 0\) for \(r < q + 1\). If \(f\) is a function, then \(\int_{\zeta \in \partial U} f(\zeta) \gamma_q(\zeta, z) = 0\) for each \(q > 0\), since \(\partial U\) has the dimension \(2^p n - 1\), hence

\[(13) \quad (B_{0U}f)(z) = \int_{\zeta \in \partial U} f(\zeta) \theta_z(\zeta),\]

since \(\gamma_0(\zeta, z) = \theta_z(\zeta)\). If \(f\) is a 1-form, then \(\int_{\zeta \in U} f(\zeta) \wedge \gamma_q(\zeta, z) = 0\) for each \(q > 0\), since \(U\) has the dimension \(2^p n\), consequently,

\[(14) \quad (B_{U}f)(z) = \int_{\zeta \in U} f(\zeta) \wedge \theta_z(\zeta).\]

In particular, there are identities in \(H\): \(d\xi \wedge jd\xi = d\xi j \wedge d\zeta\) and \((d\xi d\zeta)^\gamma = [d\xi]d\zeta\) for each \(\xi, \zeta \in \tilde{H}\). Then
\[(i) \quad d\xi \wedge jd\xi \wedge d\bar{\zeta} = d\bar{\zeta} j \wedge d\xi = 0,\]
\[(ii) \quad d\xi \wedge jd\xi \wedge jd\bar{\zeta} = d\bar{\zeta} j \wedge d\xi = 0,\]
\[(iii) \quad d\xi \wedge d\bar{\zeta} \wedge d\xi j \wedge d\bar{\zeta} = 0,\]
\[(iv) \quad d\xi \wedge d\bar{\zeta} = d\xi j \wedge d\bar{\zeta} = 0,\]
\[(v) \quad d\xi \wedge jd\xi \wedge jd\bar{\zeta} = d\bar{\zeta} j \wedge d\xi = 0,\]
\[(vi) \quad d\xi \wedge jd\xi \wedge jd\bar{\zeta} j \wedge d\xi j = 0.\]

Write \(\xi \in A_p\) in the form \(\xi = \alpha + \beta l\), then \(\bar{\xi} = \bar{\alpha} - \beta l\), where \(\alpha \in A_{p-1}\) and \(\beta \in A_{p-1}\), \(l\) is the generator of the doubling procedure of \(A_p\) from \(A_{p-1}\) \([1]\), since there is the identity \(\beta l = l\beta\). The decomposition \(\xi = \alpha + \beta l\) is unique for each \(\xi \in A_p\), where \(\alpha = \alpha(\xi)\) and \(\beta = \beta(\xi)\) depend on \(\xi\) in general. Put
\[\kappa_{p,0}(z) := dz \wedge d\bar{z}\]
and \(\kappa_{p,q}(z) := (i_{2q}(dz i_{2q})) \wedge (i_{2q}(dz i_{2q}))\) for each \(1 \leq q \leq 2^{p-1} - 1\). From Formulas \((1 - 9)\) or from Formulas \((1 - 9)\) and induction by \(p\) with the help of doubling procedures it follows, that
\[(15) \quad \{\phi_{p,0}(z) \land \ldots \land \phi_{p,v-1}(z) \land \kappa_{p,v}(z) \land \phi_{p,v+1}(z) \land \ldots \land \phi_{p,2v-1}(z)\}_{q_0(2v-1)} = 0 \]

for each \(v = 0, 1, \ldots, 2^{p-1} - 1\).

In the \((\zeta - z, \zeta - \bar{z})\)-representation
\[|\zeta-z|^2 = \sum_{n=1}^{\infty} (s_\zeta - s_z)^2 (s_\bar{\zeta} - s_{\bar{z}})^2, \]

hence:
\[(16) \quad d\zeta|\zeta-z|^{2n} = (2^{p-1}n)|\zeta-z|^{2n-2} \sum_{s=1}^{n} \{(d s_\zeta)(s_\zeta - s_z) + (s_\bar{\zeta} - s_{\bar{z}}) d s_\zeta\}.
\]

From Formulas (15, 16) it follows, that
\[(17) \quad d\zeta(|\zeta-z|^{2n}\bar{\zeta}_s(\zeta)) = C'_{p,2^{p-1}n}\{w_{2p}(1) \land \ldots \land w_{2p}(n)\}_{q(n)}, \]

since \(d\zeta = \partial\zeta + d\zeta\). Now calculate \(d\zeta\bar{\zeta}(\zeta)\) in \(U \setminus \{z\}\) using Formulas (15 - 17):
\[(18) \quad d\zeta\bar{\zeta}(\zeta) = 0.
\]

There exists \(\epsilon_0 > 0\) such that for each \(0 < \epsilon < \epsilon_0\) the ball \(B(A^p_n, z, \epsilon) := \{\zeta \in A^p_n : |\zeta - z| \leq \epsilon\}\) and hence the sphere \(S(A^p_n, z, \epsilon) := \{\zeta \in A^p_n : |\zeta - z| = \epsilon\} = \partial B(A^p_n, z, \epsilon)\) are contained in \(U\). Apply the Stokes’ formula for vector-valued functions and differential forms componentwise, using the Euclidean space \(\mathbb{R}^{2pn}\) underlying \(A^p_n\), then
\[(19) \quad \int_{S(A^p_n, z, \epsilon)} f(\zeta)\theta(z) = \int_{\partial U} f(\zeta)\theta(z) - \int_{\partial U} (df(\zeta) \land \theta(z)), \quad U_\epsilon := U \setminus B(A^p_n, z, \epsilon), \]

Since \(0 < \epsilon < \epsilon_0\). Therefore, from (15, 18) it follows, that
\[(20) \quad B_U df = B_U \tilde{df}, \quad \text{since} \quad df = \partial f + \tilde{df}, \quad \partial f(\zeta) = (\partial f(\zeta)/\partial \zeta) d\zeta, \quad \tilde{df}(\zeta) = (\partial f(\zeta)/\partial \zeta) d\zeta, \quad f(\zeta) = f(\zeta, \bar{\zeta}) \quad \text{is the abbreviated notation.}
\]

In view of Formula (18) and the Stokes’ formula:
\[(21) \quad \int_{S(A^p_n, z, \epsilon)} \theta(z) = [(2\pi)^{2p-1-n}/(2n)!][!e^{-4n}] \int_{B(A^p_n, z, \epsilon)} (d\zeta e = e, \quad \text{where} \quad d\zeta \quad \text{is the standard volume element of the Euclidean space} \quad \mathbb{R}^{2pn}.
\]

In the even dimensional Euclidean space \(\mathbb{R}^{2k}\) the volume \(V_{2k}\) of the ball of radius 1 relative to the standard Lebesgue measure \(\lambda\) with \(\lambda([0, 1]^{2k}) = 1\) is \(V_{2k} = (2\pi)^k/(2k)!!\) (see §XI.4.2, Example 3, in [27]). Then Formula (21) implies, that
\[\lim_{\epsilon \to 0} \int_{S(A^p_n, z, \epsilon)} f(\zeta)\theta(z) = f(z), \quad \text{since} \quad \int_{S(A^p_n, z, \epsilon)} (f(\zeta) - f(z))\theta(z) = e^{-2pn+1} \int_{S(A^p_n, z, \epsilon)} (f(\zeta) - f(z))|\zeta - z|^{2n-1}\theta(z)(\zeta), \quad \text{The form} \quad |\zeta - z|^{2n-1}\theta(z)(\zeta) \quad \text{is bounded on} \quad U, \quad \text{consequently,} \quad |\zeta - z|^{2n-1}\theta(z)(\zeta) \leq C_1 \max |(f(\zeta) - f(z))| \quad \zeta \in B(A^p_n, z, \epsilon), \quad \text{where} \quad C_1 \quad \text{is a positive constant independent of} \quad f \quad \text{and} \quad \epsilon \quad \text{for each} \quad 0 < \epsilon < \epsilon_0.
\]

Therefore, Formula (1) follows from Formula (19) by taking the limit when \(\epsilon > 0\) tends to zero and using Identity (20).

3.3. **Corollary.** Let \(U\) be an open subset in \(A^p_n, 2 \leq p \in \mathbb{N}\), and \(f\) be a continuous function on \(\text{cl}(U)\) and \(A^p_n\)-holomorphic on \(U\). Then
\[(1) \quad f = B_U f \quad \text{on} \quad U,
\]

where \(B_U\) and \(\partial B_U\) are the integral operators given by Equations 3.1. (13, 14).

**Proof.** From \(\tilde{\partial} f = 0\), since \(\partial f(\zeta)/\partial \zeta = 0\), and Formula 3.2.1 implies Formula 3.3.1.

3.4. **Definitions and Notations.** Suppose that \(U\) is a bounded open subset in \(A^p_n\) and \(\psi(\zeta, z)\) be an \(A^p_n\)-valued \(C^1\)-function (by the corresponding real variables) defined on \(V \times U\), where \(V\) is a neighbourhood of \(\partial U\) in \(A^p_n\), such that
\[(1) \quad \psi(\zeta, z) \neq 0 \quad \text{for each} \quad (\zeta, z) \in \partial U \times U. \quad \text{Then} \quad \psi\text{ is called an} \quad A^p_n\text{-boundary distinguishing map. Consider the function:}
\]
\[(2) \quad \eta(\zeta, z, \lambda) := \lambda(\zeta - z) < \zeta - z; \zeta - z >^{-1}
\]
\[(+1 - \lambda)\psi(\zeta, z) < \zeta - z; \psi(\zeta, z) >^{-1},
\]

(see Formula 3.1. (viii)) and the differential forms:
\[(3) \quad \phi_{p,0}(\zeta, \eta(\zeta, z, \lambda), s(\zeta)) := [(\partial \ast \phi_{p,0}(\zeta, \eta(\zeta, z, \lambda), s(\zeta))\land d s(\zeta)],
\]
\[(4) \quad \phi_{p,0}(\zeta, \eta(\zeta, z, \lambda), s(\zeta)) := (i_{2u})([(\partial \ast \phi_{p,0}(\zeta, \eta(\zeta, z, \lambda), s(\zeta)\land d s(\zeta))\land (i_{2u}(d s(\zeta)i_{2u})),
\]
\[(5) \quad \phi_{p,0}(\zeta, \eta(\zeta, z, \lambda), s(\zeta)) := (i_{2u}(\ast \phi_{p,0}(\zeta, \eta(\zeta, z, \lambda), s(\zeta))\land d s(\zeta)),
\]
\[ \tilde{\phi}_{p,u}(s\tilde{\psi}(\zeta, z), 0, s\zeta) := (i_{2u}\{[\tilde{\phi}_{p,u}(s\tilde{\psi}(\zeta, z), 0)]i_{2u}\}) \land (i_{2u}(d^s\iota_{2u})) \text{ for each } u > 0, \]
\[ (6) \quad \tilde{w}_{p,0}(s\tilde{\psi}(\zeta, z), s\zeta) := C_p(\tilde{\phi}_{p,0}(s\tilde{\psi}(\zeta, z), s\zeta) \land \tilde{\phi}_{p,1}(s\tilde{\psi}(\zeta, z), s\zeta) \land \ldots \land \tilde{\phi}_{p,2p-1}(s\tilde{\psi}(\zeta, z), s\zeta)) \big|_{\tilde{R}_{2p-1}(s\zeta, z)} \]
where \( C_p = \{(2^p - 2)2(2^{p-1} - 1)\} \).
\[ (7) \quad \tilde{w}_{2p,u}(s\tilde{\psi}(\zeta, z), s\zeta) := \{(\tilde{\phi}_{p,0}(s\tilde{\psi}(\zeta, z), s\zeta) \land \ldots \land \tilde{\phi}_{p,u-1}(s\tilde{\psi}(\zeta, z), s\zeta) \land \tilde{\phi}_{p,u}^f(s\tilde{\psi}(\zeta, z), s\zeta) \land \tilde{\phi}_{p,u+1}(s\tilde{\psi}(\zeta, z), s\zeta) \land \ldots \land \tilde{\phi}_{p,2p-1}(s\tilde{\psi}(\zeta, z), s\zeta)) \big|_{\tilde{R}_{2p-1}(s\zeta, z)} \]

proof. Then analogously to (3 - 7) there are defined \( \tilde{\phi}_{p,u}(s\tilde{\psi}(\zeta, z)), \tilde{\phi}_{p,u}^f(s\tilde{\psi}(\zeta, z)), \tilde{w}_{2p}(s\tilde{\psi}(\zeta, z), s\zeta), \tilde{w}_{2p,u}(s\tilde{\psi}(\zeta, z), s\zeta) \) for each \( u \geq 0 \) with \( s\tilde{\psi}(\zeta, z) \) instead of \( s\tilde{\psi}(\zeta, z) \);
\[ (8) \quad \tilde{\phi}_{p,z} := \tilde{\phi}_{p,z}(\psi(\zeta, z); \zeta) := C'_p < \psi(\zeta, z); -\zeta > -2^{p-1}n \]
\[ \begin{aligned} \tilde{w}_{2p,u}(s\tilde{\psi}(\zeta, z), s\zeta) \land \tilde{w}_{2p}(s^{1+}\tilde{\psi}(\zeta, z), s^{1+}z) \land \ldots \land \tilde{w}_{2p}(s^{n}\tilde{\psi}(\zeta, z), n\zeta) \big|_{\tilde{R}_{2p}(n\zeta)} \end{aligned} \]
\[ (9) \quad \tilde{\phi}_{p,z} := \tilde{\phi}_{p,z}(\psi(\zeta, z); \zeta) := C'_p \sum_{s=1}^{2p-1-1} \sum_{u=0}^{2p-1-1} \{\tilde{w}_{2p}(1\tilde{\psi}(\zeta, z), 1z) \land \ldots \land \tilde{w}_{2p}(s^{1-}\tilde{\psi}(\zeta, z), s^{1-}z) \land \tilde{w}_{2p}(s^{n}\tilde{\psi}(\zeta, z), n\zeta) \big|_{\tilde{R}_{2p}(n\zeta)} \]
If \( f \) is a bounded differential form on \( U \), then define the integral operators:
\[ (10) \quad (L_{\tilde{\phi}_{p,u}} f)(z) := \int_{\tilde{\phi}_{p,u}(\psi(\zeta, z); \zeta)} f(\zeta) \land \tilde{\phi}_{p,z}(\psi(\zeta, z); \zeta), \]
\[ (11) \quad (R_{\tilde{\phi}_{p,u}} f)(z) := \int_{\tilde{\phi}_{p,u}(\psi(\zeta, z); \zeta)} f(\zeta) \land \tilde{\phi}_{p,z}(\psi(\zeta, z); \zeta). \]
3.5. Theorem. Let \( U \) be an open subset in \( A_{p}^\circ \), \( 2 \leq p \in \mathbb{N} \), with a piecewise \( C^1 \)-boundary and let \( \psi \) be an \( A_{p} \)-boundary distinguishing map for \( U \). Suppose that \( f \) is a continuous mapping \( f : \text{cl}(U) \rightarrow A_{p} \) such that \( \tilde{\phi} f \) is also continuous on \( U \) in the sense of distributions and has a continuous extension on \( \text{cl}(U) \). Then
\[ (1) \quad f = (L_{\tilde{\phi}_{p,u}} f) - (R_{\tilde{\phi}_{p,u}} f) - (B_{\tilde{\phi}_{p,u}} f) \] on \( U \),
where the \( A_{p} \) integral operators \( B_{\tilde{\phi}_{p,u}}, L_{\tilde{\phi}_{p,u}}, \) and \( R_{\tilde{\phi}_{p,u}} \) are given by Equations 3.1.13, 3.4.10, 11.
proof. There is the decomposition:
\[ (2) \quad \tilde{\phi}_{p,z} := \sum_{q=0}^{2p-1-n-1} \tilde{T}_q^z(\psi(\zeta, z), \zeta), \]
where \( \tilde{T}_q^z(\psi(\zeta, z), \zeta) \) is a differential form with all terms of degree \( q \) by \( z \) and \( \tilde{z} \) and their multiples on \( A_{p} \) constants and of degree \( 2p-1-q-1 \) by \( (\zeta, \lambda) \) (including \( \tilde{\zeta} \) and \( \zeta \) of \( A_{p} \) constants). A differential form \( f \) has Decomposition 3.2.12. If \( \psi(z) \) is an \( A_{p} \) \( z \)-superdifferential nonzero function on an open set \( V \) in \( A_{p} \), then differentiating the equality \( (\psi(z))(\psi(z))^{-1} = -e \) gives \( (\psi(z))\{d_z(\psi(z))^{-1}\}h = -(d_z(\psi(z)).h)(\psi(z))^{-1} \) for each \( z \in V \) and each \( h \in A_{p} \). Then
\[ \int_{\zeta < \psi(\zeta, z), \zeta, \lambda} f_r(z) \land \tilde{T}_q^z(\psi(\zeta, z), \zeta, \lambda) = 0 \text{ for each } r \neq q + 1, \]
since \( \dim(\partial U) = 2p-1, d\zeta \land d\lambda = 0 \) and \( d\lambda \) commutes with each \( b \in A_{p} \). Therefore,
\[ (3) \quad R_{\tilde{\phi}_{p,u}} f_r = \int_{\zeta < \psi(\zeta, z), \zeta, \lambda} f_r(z) \land \tilde{T}_q^z(\psi(\zeta, z), \zeta) \land \tilde{T}_r^{-1}(\psi(\zeta, z), \zeta) \land \tilde{T}_r^{-1}(\psi(\zeta, z), \zeta) = 0 \text{ for each } 1 \leq r \leq 2p-1, \]
and \( R_{\tilde{\phi}_{p,u}} f_r = 0 \) for \( r = 0 \) or \( r > 2p-1 \). In particular, if \( f = f_1 \), then
\[ (4) \quad R_{\tilde{\phi}_{p,u}} f_1 = \int_{\zeta < \psi(\zeta, z), \zeta, \lambda} f_1(z) \land \tilde{\phi}_{p,z}(\psi(\zeta, z), \zeta) \land \tilde{\phi}_{p,z}(\psi(\zeta, z), \zeta) \]
where \( \tilde{\phi}_{p,z}(\psi(\zeta, z), \zeta) \) is obtained from \( \tilde{\phi}_{p,z}(\psi(\zeta, z), \zeta) \) by substituting all \( \tilde{\theta}, \psi, \zeta, \zeta \) in Formulas
of Theorem 2. On the other hand, with the help of Formulas 3.2(1–9, 15) each $A_p$ external derivative $\partial s \zeta$ can be replaced on $d s \zeta$ in $\partial_{\zeta, \lambda}(\psi, z; \zeta)$ in Formula (4). For $\phi_{\zeta, z}$ there is the decomposition:

(5) $\phi_{\zeta, z} = \sum_{q=0}^{2^n-1} \psi_q(\zeta, z)$, where $\psi_q(\zeta, z)$ is a differential form with all terms of degree $q$ by $z$ and $\bar{z}$ and their multiples on $A_p$ constants and of degree $2^n - q - 1$ by $\zeta$ and $\bar{\zeta}$ and their multiples on $A_p$ constants. Therefore,

(6) $L^\psi_{\partial U} f_r = \int_{\zeta \in \partial U} f_r \wedge \psi_r(\zeta, z)$ for each $0 \leq r \leq 2^n - 1$

and $L^\psi_{\partial U} f = 0$ for $r \geq 2^n - 1$. In particular, for $f = f_0$:

(7) $L^\psi_{\partial U} f_0 = \int_{\zeta \in \partial U} f_0(\zeta) \phi_{\zeta}(\psi, z; \zeta)$,

where $\phi_{\zeta}(\psi(\zeta, z))$, is obtained from $\phi_{\zeta, z}(\psi(\zeta, z); \zeta)$ by substituting all $\partial_{\zeta, z}$ in Formulas 3.4.(3–10) on $\partial_{\zeta}$. In view of Formula 3.2(1) it remains to prove, that $R^\psi_{\partial U} \partial f = L^\psi_{\partial U} f - B_{\partial U} f$ on $U$. For each $\zeta$ in a neighborhood of $\partial U$ there is the identity:

(8) $<\eta^\psi(\zeta, z; \lambda); \zeta - z >= 1$ for each $0 \leq \lambda \leq 1$, hence $d_{\zeta, \lambda} < \eta^\psi(\zeta, z; \lambda); \zeta - z >= 0$. By Formulas 3.2(15–18):

(9) $d_{\zeta, \lambda} \phi_{\zeta, z, \lambda} = 0$. From Identities 3.2(15–18) it follows, that

(10) $\partial_{\zeta} f \wedge \bar{\zeta}_{\lambda} = 0$. Therefore, from (4), (9), (10) it follows, that

(11) $d_{\zeta, \lambda}[f(\zeta) \phi_{\zeta, \lambda}] = [\bar{\zeta}_{\lambda} f(\zeta)] \wedge \bar{\zeta}_{\lambda, \lambda}$, since $\partial_{\zeta, \lambda} f(\zeta) = \sum_{s=1}^{\lambda} (\partial f(\zeta, \zeta) / \partial s \zeta). d s \zeta$. Due to Formulas 3.2(15–17) and 3.4(1–9):

(12) $\phi_{\zeta, \lambda}|_{\lambda=0} = \phi_{\zeta}$, $\phi_{\zeta, \lambda}|_{\lambda=1} = \theta_{\zeta}(\zeta)$. If $\zeta, z, \lambda$ is a differential form over $A_p$, then $\zeta, z, \lambda = \sum_{s=0}^{2^n} \psi_s(\zeta_0, ..., \zeta_{2^n-1}, z_0, ..., z_{2^n-1}, \lambda) \iota_s$, where $\zeta = \zeta_0, ..., \zeta_{2^n-1}, z_0, ..., z_{2^n-1}, \lambda \in R$, $\{i_0, ..., i_{2^n-1}\}$ denotes the set of standard generators of $A_p$, $\Psi$ is with values in $R$ for each $s = 0, ..., 2^n - 1$. From the Stoke’s formula for vector-valued differential forms, in particular, for $[f(\zeta) \phi_{\zeta, \lambda}(\psi, z; \zeta)]$ on $\partial U \times [0, 1]$ and Formulas (4), (7), (11), (12) above it follows the statement of this theorem.

3.6. Corollary. Let conditions of Theorem 3.5 be satisfied and let $f$ be an $A_p$ holomorphic function on $U$, then $f = L^\psi_{\partial U} f$ on $U$.

3.7. Remark. For $n = 1$ Formula 3.2.(1) produces another analog of the Cauchy-Green formula (see Theorem 2.1 and Remark 2.1.1) without using the $A_p$ line integrals. This is caused by the fact that the dimension of $A_p$ over $R$ is greater, than 2: $dim_{R} A_p = 2^n$, that produces new integral relations. Theorem 3.2 can be used instead of Theorem 2.1 to prove theorems 2.3 and 2.11 with differential forms of Theorem 3.2 instead of differential forms of Theorem 2.1).

If $\psi(\zeta, z) = \zeta - z$, then $L^\psi_{\partial U} = B_{\partial U}$ and $R^\psi_{\partial U} = 0$, hence Formula 3.5.(1) reduces to Formula 3.2.(1). For a function $f$ or a 1-form $f$ Formulas 3.2.(13, 14) respectively are valid as well for $\partial f(\zeta, z)$ instead of $\theta_{\zeta}(\zeta)$, where $d_{\zeta, \lambda} \partial_{\zeta}(\zeta, z) = 0$ for each $\zeta \neq z$. A choice of $\phi_{\zeta, s}$ and $w_{2p}$ is not unique, for example, $d \zeta \wedge d \zeta \wedge d \zeta \wedge d \zeta$ may be taken in $H$, since it gives up to a multiplier $C e$, where $C$ is a real constant, the canonical volume element in $H$ and $d \zeta \wedge d \zeta \wedge d \zeta \wedge d \zeta = 0$.

Formulas 3.2.(1) and 3.5.(1) for functions of $A_p$ variables are the $A_p$ analogs of the Martinelli-Bochner and the Leray formulas for functions of complex variables respectively, where $\psi(\zeta, z)$ is the $A_p$ analog of the Leray complex map (see §3.4). In the $A_p$ case the algebra of differential forms bears the additional gradation structure and have another properties, than in the complex case (see also §§2.8 and 3.7 [19]). Lemma 3.9 below shows, that the $A_p$ boundary distinguishing maps exist.

3.8. Definitions and Notations. Let a subset $U$ in $A_p^\rho$, $2 \leq p \in N$ or $p = \Lambda$, be given
by the equation:

(1) \( U := \{ z \in A^n_p : \rho(z) < 0 \} \), where \( \rho \) is a real-valued \( C^2 \)-function such that there exists a constant \( \epsilon_0 > 0 \) for which:

(2) \( \sum_{m=1}^{2p,n} (\partial^2 \rho(z)/\partial x_i \partial x_m) l_i t_m \geq \epsilon_0 |t|^2 \) for each \( t \in \mathbb{R}^{2p,n} \) for finite \( p \) with \( l = \sum_{m=1}^{2p,n} x_{m+1} m_1 m_{m+1} S_m, S_m := i_{m+1} \) for each \( m, x_i \in \mathbb{R} \); or

(2)' \( \sum_{m=1}^{2p,n} (\partial^2 \rho(z)/\partial l^i z \partial m^j) (l, m^j) \geq \epsilon_0 |h|^2 \) for each \( h \in \mathbb{A}^n_p \) for infinite \( p = \Lambda \), where \( z = (1^i z, \ldots, n^i z) \), \( l \in \mathbb{A}_p \). Then \( U \) is called strictly convex open subset (with \( C^2 \)-boundary). Let

(3) \( w_\rho(z) := (\partial \rho(z)/\partial l^i z, \ldots, \partial \rho(z)/\partial n^j z) \).

Put for finite \( 2 \leq p \in \mathbb{N} \)

\( v_\rho(z) := \sum_{m=1}^{2p,n} (w_\rho(z) S_m) S_m \), where as usually \( w_\rho S_m = (d_z \rho(z)) S_m \) is the differential of the function \( \rho \).

For infinite \( p = \Lambda \) take a collar neighborhood \( V \) for \( \partial U \) such that for each \( \zeta \in V \) there exists a unique point \( \xi \in \partial U \), for which \( \zeta \) belongs to the segment of the straight line intersecting \( \partial U \) at the point \( \xi \) along an outside normal (perpendicular) vector \( n_\xi \in \partial U \) at the point \( \xi \in \partial U \), \( \xi = \zeta(\zeta) \). Put

\( < v_\rho(\zeta); h > := \sum_{m=1}^{2p,n} \langle (\partial \rho(\zeta)/\partial \zeta) S_m \rangle S_m, h >, \)

where \( h \in \mathbb{A}^n_p \), that defines \( v_\rho \), since \( \| h \| < \infty \) for each \( h \in \mathbb{A}^n_p \) and \( (\partial \rho(\zeta)/\partial \zeta) \in C^1 \) is a bounded operator for each \( \zeta \).

3.9. Lemma. Let the function \( v_\rho \) be as in \( \S 3.8 \). Then \( v_\rho \) is the \( \mathbb{A}_p \)-boundary distinguishing map for \( U \).

Proof. Since \( S_m S_l = (-1)^{\kappa(S_m)\kappa(S_l)} S_l S_m \) for each \( m \neq l \), where \( \kappa(S_1) = 0, \kappa(S_m) = 1 \) for each \( m > 1 \), then

\( < v_\rho(\zeta); \zeta \neq z > + < \zeta - z; v_\rho(\zeta) > = 2 \sum_{l=1}^{2p,n} (\partial \rho(\xi)/\partial x_l) x_l (\xi - z), \)

when \( p \) is finite, where \( x_i = x_i(\zeta) \) and \( x_i(\zeta - z) \) are real coordinates corresponding to \( \zeta \) and \( \zeta - z \). For infinite \( p = \Lambda \) there is the equality:

\( < v_\rho(\zeta); \zeta - z > + < \zeta - z; v_\rho(\zeta) > = 2 \Re [\sum_{l=1}^{2p,n} (\partial \rho(\xi)/\partial x_l) (l(\xi - l z))]. \)

By the Taylor’s theorem:\n
\( \rho(z) = \rho(\zeta) - < v_\rho(\zeta); \zeta - z > + < < \zeta - z; v_\rho(\zeta) > > /2 - < \zeta - z; v_\rho(\zeta) > /2 + \sum_{l=1}^{2p,n} (\partial^2 \rho(\xi)/\partial x_l^2) m^l_1 m^2_2 ((\zeta - l z), (m^l_2 z - m^2_2 z))/(2 + o(|\zeta - z|^2)). \)

Therefore, there exists a neighborhood \( V \) of \( \partial U \) and \( \epsilon_0 > 0 \) such that

(1) \( < v_\rho(\zeta); \zeta - z > + < \zeta - z; v_\rho(\zeta) > /2 \geq \rho(\zeta) - \rho(z) + \epsilon_0 |\zeta - z|^2/4 \) for each \( \zeta \in V \) and \( |\zeta - z| \leq \epsilon_1 \), where \( a = \sum_{m} a_m S_m \) for all \( a \in \mathbb{A}_p, a_m \) are reals. If \( z \in U, \zeta \in \partial U, |\zeta - z| \leq \epsilon_1 \), then by (1):\n
\( < v_\rho(\zeta); \zeta - z > + < \zeta - z; v_\rho(\zeta) > > - \rho(z) > 0. \)

If \( |\zeta - z| > \epsilon_1 \), put \( z_1 := (1 - \epsilon_1 |\zeta - z| - 1) \zeta + \epsilon_1 \zeta - z - 1 \zeta, \) then \( \zeta - z_1 = \epsilon_1 |\zeta - z| - 1 \zeta, \) consequently,

\( < v_\rho(\zeta); \zeta - z > + < \zeta - z; v_\rho(\zeta) > > \epsilon_1 |\zeta - z| - 1 \zeta - z, \)

Evidently, \( U \) is convex and \( z_1 \in U \).

3.10. Theorem. Let \( U \) be a strictly convex open subset in \( \mathbb{A}^n_p \), \( 2 \leq p \in \mathbb{N} \) or \( p = \Lambda \), (see \( \S 3.8(1) \)) and let \( f \) be a continuous function on \( U \) with continuous \( \partial f \) on \( U \) in the sense of distributions having a continuous extension on \( cl(U) \) such that \( 2.11(ii) \) is satisfied. Then there exists a function \( u \) on \( U \) which is a solution of the \( \partial \)-equation \( 2.11(ii) \).

Proof. Reduce the proof to the finite case as in \( \S 2.3. \) In proofs of Theorems 2.3 and 2.11 take in Formula 3.5(1) \( \chi f \) instead of \( f \), which is possible due to Lemma 3.9, choosing \( \psi = v_\rho \) and \( \text{supp}(\chi) \) as a proper subset of \( U \). Then \( L_{\partial U} \chi f = 0 \) and \( R_{\partial U} \chi f = 0 \), hence \( \chi f = -B_{\partial U} \partial f \).

For each fixed \( z \in U \) a subset \( U_z := \{ \xi \in \mathbb{A}_p : \rho(1^i z, \ldots, l^i z, \xi, \ldots, n^i z) < 0 \} \) is strictly convex in \( \mathbb{A}_p \) due to \( 3.8(1,2) \), where \( \eta := (1^i z, \ldots, l^i z, l^{1+1} z, \ldots, n^i z) \). Apply 3.5(1) by a variable \( \xi \) in \( U_z, \) in particular, for \( l = 1, \) for which \( v_\rho \) by the variable \( \xi \) is the \( \mathbb{A}_p \)-boundary distinguishing map for \( U_z \). Therefore, \( u(z) := -B_{\partial U} \chi f(\xi, \eta) . d\xi \) with \( z = (\xi, \eta), \xi \in U_z \) solves the problem.
4 Manifolds over Cayley-Dickson algebras

4.1. Definitions and Notations. Suppose that $M$ is an $\mathcal{A}_p$ manifold and let $RL(N,\mathcal{A}_p)$ be the family of all right $\mathcal{A}_p$-superlinear operators $A : \mathcal{A}_p^N \rightarrow \mathcal{A}_p^N$, where $2 \leq p \in \mathbb{N}$ or $p = \Lambda$. Then an $\mathcal{A}_p$ holomorphic vector bundle $Q$ of $\mathcal{A}_p$ dimension $N$ over $M$ is a $C^\infty$-vector bundle $Q$ over $M$ with the characteristic fibre $\mathcal{A}_p^N$ together with an $\mathcal{A}_p$ holomorphic atlas of local trivializations: $g_{a,b} : U_a \cap U_b \rightarrow RL(N,\mathcal{A}_p)$, where $U_a \cap U_b \neq \emptyset$, $\{ (U_a, h_a) : a \in \mathcal{Y} \} = At(Q)$, $U_a U_a = M$, $U_a$ is open in $M$, $h_a : Q|_{U_a} \rightarrow U_a \times \mathcal{A}_p^N$ is the bundle isomorphism, $(z, g_{a,b}(z)v) = h_a \circ h_b^{-1}(z, v)$, $z \in U_a \cap U_b$, $v \in \mathcal{A}_p^N$. If $Y_N$ is the underlying to $\mathcal{A}_p^N$ real vector space, then suppose, that each $g_{a,b}$ induces a $\mathbb{R}$-linear isomorphism of $Y_N$ onto itself. Since $M$ has the real underlying manifold $M_{\mathbb{R}}$, then there exists the tangent bundle $TM$ such that $T_{\mathbb{R}}M$ is isomorphic with $\mathcal{A}_p^N$ for each $x \in M$, since $TU_a = U_a \times \mathcal{A}_p^n$ for each $a$, where $dim_{\mathcal{A}_p} M = n$ is the $\mathcal{A}_p$ dimension of $M$.

If $X$ is a Banach space over $\mathcal{A}_p$ (with left and right distributivity laws relative to multiplications of vectors in $X$ on scalars from $\mathcal{A}_p$), then denote by $X^*_q$ the space of all additive $\mathbb{R}$-homogeneous functionals on $X$ with values in $\mathcal{A}_p$. Clearly $X^*_q$ is the Banach space over $\mathcal{A}_p$. Then $T^*M$ with fibres $((\mathcal{A}_p^n)^*)^*$ denotes the $\mathcal{A}_p$ cotangent bundle of $M$ and $\Lambda^*T^*M$ denotes the vector bundle whose sections are $\mathcal{A}_p$ $r$-forms on $M$, where $S_0^2x_b \wedge S_0^adx_a = (-1)^{(S_a)e(S_b)} S_a^ax_a \wedge S_b^bx_b$ for each $S_a \neq S_b \in \{ i_0, ..., i_{2p-1} \}$, $dz = \sum_{m=1} z^m d^1 m S_m$, $z \in \mathcal{A}_p$, $x_b \in \mathbb{R}$.

The $\mathcal{A}_p$ holomorphic Cousin data in $Q$ is a family $\{ f_{a,b} : a, b \in \mathcal{Y} \}$ of $\mathcal{A}_p$ holomorphic sections $f_{a,b} : U_a \cap U_b \rightarrow Q$ such that $f_{a,b} + f_{b,l} = f_{a,l}$ in $U_a \cap U_b \cap U_l$ for each $a, b, l \in \mathcal{Y}$. A finding of a family $\{ f_a : a \in \mathcal{Y} \}$ of $\mathcal{A}_p$ holomorphic sections $f_a : U_a \rightarrow Q$ such that $f_{a,b} = f_a - f_b$ in $U_a \cap U_b$ for each $a, b \in \mathcal{Y}$ will be called the $\mathcal{A}_p$ Cousin problem.

4.2. Theorem. Let $M$ be an $\mathcal{A}_p$ manifold and $Q$ be an $\mathcal{A}_p$ holomorphic vector bundle on $M$, where $2 \leq p \in \mathbb{N}$ or $p = \Lambda$. Then Conditions (i, ii) are equivalent:

(i) each $\mathcal{A}_p$ holomorphic Cousin problem in $M$ has a solution;

(ii) for each $\mathcal{A}_p$ holomorphic section $f$ of $Q$ such that $\partial f = 0$ on $M$, there exists a $C^\infty$-section $U$ of $Q$ such that $(\partial u/\partial \bar{z}) = \hat{f}$ on $M$.

Proof. (i) $\Rightarrow$ (ii). In view of Theorems 2.11 and 3.10 there exists an (open) covering $\{ U_a : a \}$ of $M$ and $C^\infty$-sections $u_b : U_b \rightarrow Q$ such that $(\partial u_b/\partial \bar{z}) = \hat{f}$ in $U_b$. Then $(u_b - u_l)$ is $\mathcal{A}_p$ holomorphic in $U_l \cap U_b$ and their family forms the $\mathcal{A}_p$ holomorphic Cousin data in $Q$.

Put $u := u_b - h_b$ on $U_b$, where $u_b - u_l = h_b - h_l$, $h_b : U_b \rightarrow Q$ is an $\mathcal{A}_p$ holomorphic section given by (i).

(ii) $\Rightarrow$ (i). Take a $C^\infty$-partition of unity $\{ \chi_b : b \}$ subordinated to $\{ U_b : b \}$ and $c_b := -\sum_a \chi_a f_{a,b}$ on $U_b$, then $f_{t,b} = \sum_a \chi_a (f_{t,a} + c_{a,b}) = c_l - c_b$ in $U_l \cap U_b$, hence $(\partial c_l/\partial \bar{z}) = (\partial c_b/\partial \bar{z})$ in $U_l \cap U_b$. By (ii) there exists a $C^\infty$-section $u : M \rightarrow Q$ with $(\partial u/\partial \bar{z}) = (\partial c_b/\partial \bar{z})$ on $U_b$ and $h_b := c_b - u$ on $U_b$ gives the solution.

4.3. Definitions. Suppose $U$ is an open subset in $\mathcal{A}_p$, then a $C^2$-function $\rho : U \rightarrow \mathbb{R}$ is called subharmonic (strictly subharmonic) in $U$ if $\sum_{m=1}^{2p} \partial^2 \rho/\partial x_m^2 \geq 0$ ($\sum_{m=1}^{2p} \partial^2 \rho/\partial x_m^2 > 0$ correspondingly) for finite $p \geq 2$; or

$$(\partial^2 \rho(z)/\partial z \partial \bar{z} )(\xi, \bar{\xi}) \geq 0 \text{ (or } > 0) \text{ for each } z \in U \text{ and each } 0 \neq \xi \in \mathcal{A}_p \text{ for } p = \Lambda, \text{ where } z = \sum_{m=1}^{2p} x_m S_m U, \text{ where } x_m \in \mathbb{R} \text{ for each } m.$$

If $U$ is an open subset in $\mathcal{A}_p$, then a $C^2$-function $\rho : U \rightarrow \mathbb{R}$ such that the function $\zeta \mapsto \rho(v + \zeta w)$ is subharmonic (strictly subharmonic) on its domain for each $v, w \in \mathcal{A}_p^n$ is called plurisubharmonic (strictly plurisubharmonic correspondingly) function, where $\zeta \in \mathcal{A}_p$. A $C^\infty$-function $\rho$ on an $\mathcal{A}_p$ manifold $M$ is called a strictly plurisubharmonic exhausting $C^\infty$-function for $M$, $2 \leq v \in \mathbb{N}$, if $\rho$ is a strictly plurisubharmonic $C^\infty$-function on $M$ and for each $\alpha \in \mathbb{R}$ the set $\{ z \in M : \rho(z) < \alpha \}$ is bounded in $M$. 

20
4.4. Theorem. Let $M$ be an $A_p$ manifold with strictly plurisubharmonic exhausting function $\rho$ such that $\rho$ is a $C^\omega_{\overline{z};\overline{z}}$-function and let $Q$ be an $A_p$ holomorphic vector bundle on $M$, $U_\alpha := \{ z \in M : \rho(z) < \alpha \}$ for $\alpha \in \mathbb{R}$, where $2 \leq p \in \mathbb{N}$ or $p = \Lambda$.

(i). Suppose that $d\rho(z) \neq 0$ for each $z \in \partial U_\alpha$, for a marked $\alpha \in \mathbb{R}$. Then every continuous section $f : \text{cl}(U_\alpha) \to Q$ which is $A_p$ holomorphic on $U_\alpha$ can be approximated (uniformly for finite $p$) on $\text{cl}(U_\alpha)$ by $A_p$ holomorphic sections of $Q$ on $M$.

(ii). For each continuous mapping $f : M \to Q$ such that $\partial f = 0$ on $M$ there exists a continuous mapping $u : M \to Q$ such that $\partial u / \partial \overline{z} = \hat{f}$ on $M$.

Proof. For a $C^\omega_{\overline{z};\overline{z}}$-function $\rho : U \to \mathbb{R}$ (that is, $\rho$ is locally analytic in variables $(z, \overline{z})$, $\mathbb{R} = \text{Re} \to A_p$) there is the identity:

$$
\sum_{l,m,a,b}(\partial^2 \rho / \partial^2 \overline{z} \partial \overline{z} \partial^m \overline{x}_a \partial^l \overline{x}_b) t_{2^p(l-1)+a} t_{2^p(l-1)+b} = \\
\sum_{l,m,a}(\partial^2 \rho (z) / \partial^l \overline{z} \partial^m \overline{z} \partial^a \overline{x}_a) ((\partial^l \overline{z} / \partial \overline{z} \partial^a \overline{x}_a) t_{2^p(l-1)+a}, (\partial^m \overline{z} / \partial \overline{z} \partial^a \overline{x}_a) t_{2^p(l-1)+b}),
$$

for each $\xi \in \mathbb{N}$ and each $\xi = (\xi_1, ..., \xi_n)$ (see also §2 [19, 20]). Consider a proper bounded closed subset $A$ in $M$ such that $d\rho(z) \neq 0$ for each $z \in A$. Then for each $\epsilon > 0$ there exists a strictly plurisubharmonic function $\rho_\epsilon : M \to \mathbb{R}$ such that $\rho_\epsilon$ is a $C^\omega_{\overline{z};\overline{z}}$-function on $M$ and (i – iii) are fulfilled:

(i) $\rho - \rho_\epsilon$ together with its first and second derivatives is not greater than $\epsilon$ on $M$;

(ii) the set $\text{Crit}(\rho_\epsilon) := \{ z \in M : d\rho_\epsilon(z) = 0 \}$ is discrete in $M$;

(iii) $\rho_\epsilon = \rho$ on $A$ (see also 2.1.2.2 [7] in the complex case).

The space $C^\omega_{\overline{z};\overline{z}}(U, A_p)$ is dense in $C^0(U, A_p^n)$ for each open $U$ in $A_p^n$ (see §2.7 and Theorem 3.28 in [19, 20]). Suppose $\beta \in \mathbb{R}$ and $d\rho(z) \neq 0$ for $z \in \partial U_\beta$ and $f : \text{cl}(U_\beta) \to Q$ is a continuous section $A_p$ holomorphic on $U_\beta$. Therefore, for each $\beta \leq \alpha < \infty$ if $d\rho(z) \neq 0$ for each $z \in \partial U_\alpha$, then $f$ can be approximated (uniformly for finite $p$) on $\text{cl}(U_\beta)$ by continuous sections on $\text{cl}(U_\alpha)$ that are holomorphic on $U_\alpha$. There exists a sequence $\beta < \alpha_1 < \alpha_2 < ...$ such that $\lim \alpha_i = \infty$ and $d\rho(z) \neq 0$ for each $z \in \partial U_\alpha$, since $\text{Crit}(\rho)$ is discrete. For each $\epsilon > 0$ and each natural number $s$ satisfying $2 \leq s \leq p$ there exists a continuous section $f_i : \text{cl}(U_{\alpha_i}) \to Q$ such that $f_i$ is $A_p$ holomorphic on $U_{\alpha_i}$ and $\| f_{l+1} - f_l \|_{C^0(U_{\alpha_l}, s)} < \epsilon^2 - l^{-1}$ for each $l \in \mathbb{N}$, where $f_0 := f$, $M_s$ denotes the $(2^s$-dimensional over $\mathbb{R}$) closed submanifold in $M$ induced by the embedding of $A_s$ into $A_p$, when $p$ is infinite, or put $M_s = M$ for finite $p$ taking $s = p$, $U_{\alpha_l,s} := U_{\alpha_l} \cap M_s$. Therefore, the sequence $\{ f_l : l \in \mathbb{N} \}$ converges to the $A_s$ holomorphic section $g : M_s \to Q$ uniformly on each compact subset $P$ in $M_s$ and $\| f - g \|_{C^0(U_{\beta,l}, s)} < \epsilon$.

The second statement (ii) follows from (i) and Theorems 2.11, 3.10, since $\text{Crit}(\rho)$ is discrete in $M$ and there exists a sequence of continuous $Q$-valued functions on $\text{cl}(U_{\alpha_l})$ such that $d\rho_\eta / \partial \overline{z} = \hat{f}$ in the sense of distributions on $U_{\alpha_l}, \cup_l U_{\alpha_l} = M$ (see also the complex case in §2.13.3 [7] mentioning, that Lemma 2.12.4 there can be reformulated and proved for an $A_p$ manifold $M$ on $A_p^n$ instead of a complex manifold on $\mathbb{C}^n$).

4.5. Definitions. Let $M$ be an $A_p$ manifold (see §2.10), where $2 \leq p \in \mathbb{N}$ or $p = \Lambda$. For a closed bounded subset $G$ in $M$ put: $G_H^M := \{ z \in M : |\rho(z)| \leq \sup_{z \in \partial G} |\hat{f}(z)| \forall f \in \mathbb{H}(M) \}$. Such $G_H^M$ is called the $\mathbb{H}(M)$-hull of $G$. If $G = G_H^M$, then $G$ is called $\mathbb{H}(M)$-convex. An $A_p$ manifold $M$ is called $A_p$ holomorphically convex if for each closed bounded subset $G$ in $M$ the set $G_H^M$ is closed and bounded.

An $A_p$ manifold $M$ with a countable atlas $\mathcal{A}(M)$ having dimension $n$ over $A_p$ and satisfying (i, ii):

(i) $M$ is $A_p$ holomorphically convex;
(ii) for each \( z \in M \) there are \( 1f; \ldots, n f \in \mathcal{H}(M) \) and there exists a neighbourhood \( U \) of \( z \) such that the map \( U \ni \zeta \mapsto (1f(\zeta), \ldots, n f(\zeta)) \) is \( A_p \) biholomorphic (see §2.6), then \( M \) is called an \( A_p \) Stein manifold.

4.6. Remark. If \( M_1 \) and \( M_2 \) are two \( A_p \) Stein manifolds, then \( M_1 \times M_2 \) is an \( A_p \) Stein manifold. If \( N \) is a closed \( A_p \) submanifold of a \( A_p \) Stein manifold \( M \), then \( N \) is also an \( A_p \) Stein manifold.

4.7. Theorem. Let \( M \) be an \( A_p \) Stein manifold, where \( 2 \leq p \in \mathbb{N} \) or \( p = \Lambda \). Then for each \( \mathcal{H}(M) \)-convex closed bounded subset \( P \) in \( M, P \neq M \) and each neighborhood \( V_P \) of \( P \) there exists a strictly plurisubharmonic exhausting \( C^\omega_{z,\bar{z}} \)-function \( \rho \) on \( M \) such that \( \rho < 0 \) on \( P \) and \( \rho > 0 \) on \( M \setminus V_P \).

The proof of this theorem is analogous to that of Theorem 2.3.14 [7] in the complex case taking \( \rho(z) := -1 + \sum_{n=1}^{\infty} 1 \sum_{k=1}^{N(\alpha)} f^k(z)(f^k(z))^2 \) for each \( z \in M, f^k \in C^\omega_{z,\bar{z}}, M = \bigcup_l P_l, P_l \subset \text{Int}(P_{l+1}) \) for each \( l \in \mathbb{N}, \) each \( P_l \) is \( \mathcal{H}(M) \)-convex, \( \sum_{k=1}^{N(\alpha)} |f^k(z)|^2 < 2^{-l} \) for each \( z \in P_l, \sum_{k=1}^{N(\alpha)} |f^k(z)|^2 \geq 1 \) for each \( z \in P_{l+1} \setminus U_l, \) \( U_l := \text{Int}(P_{l+1}), \) with the rank \( \text{rank}[(\partial f^k/\partial z)^{m}z^{n}]_{m=1, \ldots, n} = 2^n \) over \( \mathbb{R} \) for each \( z \in P_l \) for finite \( p \) or \( (f^1, \ldots, f^{N(\alpha)}) \) is regular for infinite \( p \) (see Definitions 2.6 and 4.3).

4.8. Theorem. An \( A_p \) manifold \( M \) is an \( A_p \) Stein manifold if and only if there exists a strictly plurisubharmonic exhausting \( C^\omega_{z,\bar{z}} \)-function \( \rho \) on \( M \), then \( \{z \in M : \rho(z) \leq \alpha \} \) is \( \mathcal{H}(M) \)-convex for each \( \alpha \in \mathbb{R} \), where \( 2 \leq p \in \mathbb{N} \) or \( p = \Lambda \).

Proof. The necessity follows from Theorem 4.7. To prove sufficiency suppose \( \eta = (1\eta, \ldots, n \eta) \) are \( A_p \) holomorphic coordinates in a neighbourhood \( V_\xi \) of \( \xi \in M \). Consider

\[
(1) \quad u(z) := 2 - \sum_{l=1}^{N(\alpha)} v_p(\xi) \eta(z) - \eta(\xi) + \sum_{l,m=1}^{N(\alpha)} (\partial^2 \rho(\xi)/\partial \eta^m \eta^l)(1\eta(z) - \eta(\xi), m \eta(z) - \eta(\xi)) \chi,
\]

where \( v_p(\xi) \) is given by (3.8). (Then \( u \) is holomorphic in \( V_\xi \) and \( u(\xi) = 0 \). By Lemma 3.9:

\[
(2) \quad (u(z) + u(\bar{z}))/2 = \rho(z) - \rho(\xi) - \sum_{l,m=1}^{N(\alpha)} (\partial^2 \rho(\xi)/\partial \eta^m \eta^l)(1\eta(z) - \eta(\xi), m \eta(z) - \eta(\xi)) (\partial \eta(z)/\partial \eta^l) + o(\eta(z) - \eta(\xi))^2.
\]

From the strict plurisubharmonicity of \( \rho \) it follows, that there exists \( \beta > 0 \) and \( V_\xi \) such that

\[
(3) \quad (u(z) + u(\bar{z}))/2 < \rho(z) - \rho(\xi) - \beta(\eta(z) - \eta(\xi))^2 \text{ for each } z \in V_\xi. \text{ Then } \exp(u(\xi)) = 1 \text{ and } |\exp(u(z))| < 1 \text{ for each } \xi \neq z \in cl(U_\alpha) \cap V_\xi \text{ (see Corollary 3.3 [19], Corollary 3.3 and Note 3.6.3 [20]).}
\]

If \( g : \mathbb{R} \to A_p \) is a \( C^\alpha \)-function with bounded (closed) support, then \( g(z \bar{z}) =: \chi(z) \) is a \( C^\alpha \)-function on \( A_p \) with bounded closed support such that \( \chi \) is \( A_p \) \( (z, \bar{z}) \)-superdifferentiable. Therefore, there exists a neighbourhood \( W_\xi \subset V_\xi \) of \( \xi \) and an infinitely \( (z, \bar{z}) \)-superdifferentiable function \( \chi \) such that \( \chi|W_\xi = 1 \), \( \text{supp}(\chi) \) is a proper subset of \( V_\xi \), consequently,

\[
\lim_{m \to \infty} \|\exp(mu(z))(\partial \chi(\bar{z})/\partial \bar{z})\|_{C^0(U_\alpha)} = 0,
\]

where \( (\partial \chi(z)/\partial \bar{z}) = (\partial \chi(z)/\partial \bar{z}, \ldots, \partial \chi(z)/\partial \bar{z}) \). In view of Theorem 3.10 there exist continuous functions \( v_m \) on \( cl(U_\alpha) \) such that

\[
(\partial \chi(z)/\partial \bar{z}) = \exp(mu(z))(\partial \chi(z)/\partial \bar{z}) \text{ in } U_\alpha \text{ and } \lim_{m \to \infty} \|v_m\|_{C^0(U_\alpha)} = 0.
\]

Put \( g_m(z) := \exp(mu(z))\chi(z) - v_m(z) + v_m(\xi) \), hence \( g_m \) is continuous on \( cl(U_\alpha) \) and \( A_p \) holomorphic on \( U_\alpha \). Since \( \text{supp}(\chi) \) is the proper subset in \( V_\xi \), then \( g_m(\xi) = 1 \) for each \( m \in \mathbb{N}, supm\|g_m\|_{C^0(U_\alpha)} < \infty \) and for each bounded closed subset \( P \) in \( cl(U_\alpha) \setminus \{\xi\} \) there exists \( \lim_{m \to \infty} \|g_m\|_{C^0(U_\alpha)} = 0. \)

In view of Theorem 4.4.(ii) there exists a sequence of functions \( f_m \in \mathcal{H}(M) \) and \( C = \text{const} < \infty \) such that \( (a) \ f_m(\xi) = 1 \) for each \( m \in \mathbb{N}; (b) \ |f_m|_{C^0(U_\alpha)} \leq C \) for each \( m \in \mathbb{N}; (c) \lim_{m \to \infty} \|g_m\|_{C^0(U_\alpha)} = 0 \) for each closed bounded subset \( P \subset cl(U_\alpha) \setminus \{\xi\} \).

Consider an \( A_p \) holomorphic function \( f \) on a neighborhood of \( \xi \) such that \( f(\xi) = 0 \). Put \( \phi_m := f(\xi) (\partial \chi(z)/\partial \bar{z}) \) then \( \text{supp}(\phi_m) \) is the proper subset in \( V_\xi \setminus W_\xi \). In view of Inequality (3) there exists \( \delta > 0 \) such that \( \lim_{m \to \infty} \|\phi_m\|_{C^0(U_{\alpha + 4})} = 0. \) As in §4.4 it is possible to assume, that \( \text{Crit}(\rho) \) is discrete in \( M \). Take \( 0 < \epsilon < \delta \) such that \( d\rho \neq 0 \) on \( \partial U_{\alpha + \epsilon}. \)

22
In view of Theorem 4.4.(ii) there exists a continuous function \( v_m \) on \( cl(U_{a+\delta}) \) such that \( \partial v_m/\partial \bar{z} = \hat{\phi}_m \) on \( U_{a+\epsilon} \) and \( \lim_m \| v_m \|_{C^0(U_{a+\epsilon})} = 0 \). Each \( v_m \) is \( A_p \)-holomorphic on \( W_\xi \), since \( \phi_m = 0 \) on \( W_\xi \), hence \( \lim_m \partial v_m(\xi) = 0 \). Since \( f(\xi) = u(\xi) = 0 \) and \( \chi = 1 \) on \( W_\xi \), then \( \partial g_k(\xi)/\partial \xi = \partial f(\xi)/\partial \xi - \partial v_k(\xi)/\partial \xi \), where \( g_k := f(\chi \exp(\nu_k)) - v_k \). In view of Theorem 4.4.(i) there exists \( f_m \in \mathcal{H}(M) \) such that \( \| f_m - g_m \|_{C^0(U_{a+\epsilon})} < m^{-1} \) and inevitably \( \lim_m \| \partial f_m(\xi)/\partial \xi \| < 0 \).

Let \( V_\xi \) and \( W_\xi \) be as above, then there exists \( \delta > 0 \) such that \((u(z) + \bar{u}(z))/2 < -\delta \) for each \( z \in U_{a+\delta} \cap (V_\xi \setminus W_\xi) \). Therefore, there exists a branch of the \( A_p \) logarithm \( L_n(u) \in \mathcal{H}(U_{a+\delta} \setminus (W_\xi \setminus cl(W_\xi)) \) (see §§3.7, 3.8 [19, 20]). From Theorems 4.2, 4.4 it follows that each \( A_p \) holomorphic Cousin problem on \( U_{a+\delta} \) has a solution. Hence \( L_n(u) = w_1 - w_2 \) for suitable \( w_1 \in \mathcal{H}(V_\xi \cup U_{a+\delta}) \) and \( w_2 \in \mathcal{H}(U_{a+\delta} \setminus cl(W_\xi)) \). Put \( f := u \exp(-w_1) \) in \( U_{a+\delta} \cap V_\xi \) and \( f := \exp(-w_2) \) in \( U_{a+\delta} \cap cl(W_\xi) \). Then \( f \in \mathcal{H}(U_{a+\delta}) \) and \( f(\xi) = 0 \). In view of Inequality (3) \( f(z) \neq 0 \) for each \( \xi \neq z \in cl(U_a) \). Verify now that \( cl(U_a) \) is \( \mathcal{H}(M) \)-convex. Consider \( \xi \in M \setminus cl(U_a) \). Due to §4.4 there exists a strictly plurisubharmonic exhausting \( C^\omega \)-function \( \psi \) for \( M \) such that \( Crit(\psi) \) is discrete and \( U_\alpha \subset G(\psi) \), where \( G(\beta) := \{ z \in M : \psi(z) < \beta \} \) for \( \beta \in \mathbb{R} \). Considering shifts \( \psi \mapsto \psi + const \) assume \( d\psi(z) \neq 0 \) for each \( z \in \partial G(\psi) \). From the proof above it follows, that there exists \( f \in \mathcal{H}(M) \) such that \( f(\xi) = 1 \) and \( |f(z)| < 1 \) for each \( z \in cl(U_a) \).

4.8.1. Remark. With the help of Theorem 4.8 it is possible to spread certain modifications of Theorems 3.2 and 3.5 on \( A_p \) Stein manifolds.

4.9. Theorem. Let \( N \) be an \( A_\Lambda \) manifold with \( 1 \leq s \leq \infty \) (where \( A_1 := C \)), then for each \( p \) with \( s < p \) or \( s \subset N \subset p = \Lambda, s \neq p \), there exists an \( A_\Lambda \) manifold \( M \) and an \( A_s \) holomorphic embedding \( \theta : N \rightrightarrows M \).

Proof. Suppose \( At(N) = \{(V_\alpha, \psi_\alpha) : \alpha \in \Upsilon \} \) is any \( A_\Lambda \) holomorphic atlas of \( N \), where \( V_\alpha \) is open in \( N \), \( U_\alpha V_\alpha \cap V_\beta \subset cl(V_\alpha) \) is a homeomorphism for each \( a, n = dim(A_\Lambda M) \in \mathbb{N}, \{V_\alpha : \alpha \in \Upsilon \} \) is a locally finite covering of \( N, \psi_b \circ \psi_a^{-1} \) is a holomorphic function on \( \psi_a(V_\alpha \cap V_\beta) \) for each \( a, b \in \Lambda \) such that \( V_\alpha \cap V_\beta \neq \emptyset \). Since \( A_p^n \) is normed, then it is paracompact together with \( M \) by Theorem 5.1.3 [6]. For each \( A_s \) holomorphic function \( f \) on an open subset \( V \subset A_p^n \) there exists an \( A_p \) holomorphic function \( F \) on an open subset \( U \subset A_p^n \) such that \( \pi(U) = V \) and \( F|_V = f|_V \), where \( \pi : A_p^n \rightrightarrows A_s^n \) is the natural projection (see Proposition 3.13 [19] and analogously in the general case using local analyticity and a locally finite covering of \( V \)).

Therefore, for each two charts \( (V_a, \psi_a) \) and \( (V_b, \psi_b) \) with \( V_a \cup V_b \neq \emptyset \) there exists \( U_{a,b} \subset A_p^n \) and an \( A_p \) holomorphic function \( \Psi_{a,b} \) such that \( \Psi_{a,b}|_{\psi_a(V_{a,b})} = \psi_b \circ \psi_a^{-1} \), where \( \psi_{b,a} := \psi_b \circ \psi_a^{-1}, \pi(U_{a,b}) = \psi_a(V_{a,b}) \). Consider \( Q := \bigoplus Q_a \), where \( Q_a \) is open in \( A_p^n, \pi(Q_a) = \psi_a(V_a) \) for each \( a \in \Upsilon \). The equivalence relation \( C \) in the topological space \( \bigoplus \psi_a(V_a) \) generated by functions \( \psi_a \) has an extension to the equivalence relation \( \mathcal{H} \) in \( Q \). Then \( M := Q/\mathcal{H} \) is the desired \( A_p \) manifold with \( At(M) = \{(\Psi_a, U_a) \in Q \} \) such that \( \Psi_{a,b} \circ \psi_a^{-1} = \psi_{b,a} \) for each \( U_a \cap U_b \neq \emptyset \). The family of embeddings \( \eta_a : \psi_a(V_a) \rightrightarrows U_a \) induces the \( A_s \) holomorphic embedding \( \theta : N \rightrightarrows M \).

4.10. Definition. Let \( M \) be an \( A_p \) manifold, \( 2 \leq p \in \mathbb{N} \) or \( p = \Lambda \). Suppose that for each chart \((U_a, \phi_a) \) of \( At(M) \) there exists an \( A_p \) superdifferentiable mapping \( \Gamma : u \in \phi_a(U_a) \rightrightarrows \Gamma(u) \in L_q(X, X', \mathbb{A}_p) = L_q(X, X, X') \), where \( L_q(X^n, (X_q^n)^m, Y) \) denotes the space of all quasi-linear mappings from \( X^n \times (X_q^n)^m \) into \( Y \) that is, additive and \( R \)-homogeneous by each argument \( x \) in \( X \) or in \( X_q^n \), where \( X \) and \( Y \) are Banach spaces over \( A_p \). The space of all additive \( R \)-homogeneous functionals on \( X \) with values in \( A_p \) (see §4.1),
If $U_a \cap U_b \neq \emptyset$, let

$$X^*_q = L_q(X; A_p).$$

Then for each $q \in X$ there exists a point $z \in U_b$ such that $f(z) = \phi_b^{-1}(q)$.

**4.11. Remark.** For certain an $A_p$ manifold there exists a neighbourhood $V$ of $M$ in $TM$ such that $f \circ \phi^{-1}_b \in A_p$ is holomorphic (see the real case in [9]).

**4.12. Theorem.** Let $f$ be an $A_p$ holomorphic function such that $f$ is $A_p$ (right) superlinear on a compact $A_p$ manifold $M$, where $2 \leq p \in N$. Then $f$ is constant on $M$.

**Proof.** By the supposition of this theorem $f \circ \phi_b^{-1}$ is $A_p$ (right) superlinear for each chart $(U_b, \phi_b)$ of $M$. Since $M$ is compact and $|f(z)|$ is continuous, then there exists a point $q \in M$ at which $|f(z)|$ attains its maximum. Let $q \in U_b$, then $f \circ \phi_b^{-1}$ is the $A_p$ holomorphic function on $V_b := \phi_b(U_b) \subset A_p^n$, where $\dim A_p M = n$. Consider a polydisk $V$ in $A_p^n$ with the centre $y = \phi_b(q)$ such that $V \subset V_b$. Put $g(w) = f \circ \phi_b^{-1}(y + (z - y)w)$, where $w$ is the $A_p$ variable. Then for each $z \in V$ there exists $\epsilon_z > 0$ such that the function $g(w)$ is $A_p$ holomorphic on the set $W_z := \{ w : w \in A_p, |w| < 1 + \epsilon_z \}$ and $|g(w)|$ attains its maximum at $w = 0$. In view of Theorem 3.15 and Remark 3.16 [19, 20] $g$ is constant on $W_z$, hence $f$ is constant on $U_b$. By the $A_p$ holomorphic continuation $f$ is constant on $M$.
