**Abstract:** Cs$_2$SnI$_6$ is a stable and environmentally friendly halide perovskite material with great potential for photovoltaic and optoelectronic applications. While the surface properties are of paramount importance for device fabrications, there have been no such theoretical studies on this material. Using density functional theory calculations with the SCAN+V10 functional, we studied the (001), (011) and (111) surfaces of Cs$_2$SnI$_6$ to reveal their thermodynamic stability. We constructed seven models for these surfaces, including two along the (001) orientation (CsI$^{-}$ and SnI$_6$- terminated surfaces), two along the (011) orientation (I$_2$- and Cs$_2$SnI$_5$-terminated surfaces) and three along the (111) orientation (non-stoichiometric CsI$_3$-, Sn$^-$- and stoichiometric CsI$_7$-terminated surfaces). Because most of the surfaces are non-stoichiometric, their relative stability depends on the experimental preparation condition, which is reflected by the chemical potentials of the constituent elements in the calculation. By determining the allowed chemical potential region, we analyzed the thermodynamic stability of these Cs$_2$SnI$_6$ surfaces. Our results show that the surface energies of the (001) and (011) surfaces are affected by the chemical potentials, while the stoichiometric CsI$_7$-terminated (111) surface is unaffected by the chemical potentials and is energetically the most stable surface of Cs$_2$SnI$_6$. Thus, the observed exposure of (111) surface of Cs$_2$SnI$_6$ crystals in several recent experiments is determined to be driven by thermodynamics.

**Key words:** perovskites; surface energy; Cs$_2$SnI$_6$; photovoltaics; luminescent materials

Organic-inorganic hybrid lead halide perovskites, such as CH$_3$NH$_3$PbI$_3$\cite{1-3} have attracted enormous research interests for applications in efficient photovoltaic\cite{4}, light-emitting\cite{5} and photodetection devices\cite{6}. As their lead-free counterparts, Sn-based halide perovskites, such as CH$_3$NH$_3$SnI$_3$\cite{7-9} and CsSnI$_3$\cite{10-12}, have been proposed for such applications because of their nontoxicity. However, because 2+ state is not the most stable valence state of Sn, the Sn-based perovskites are prone to further oxidation, rendering them even less stable than the Pb-based perovskites, which are already well known to have the stability issue\cite{13}. It is highly desirable to develop air-stable alternatives. For this purpose, Cs$_2$SnI$_6$ is a promising material, in which Sn is already in 4+ valence state and resistant to further oxidation\cite{14-16}. Meanwhile, it has a suitable band gap and strong optical absorption for photovoltaic applications\cite{17-19}.

The halide perovskite materials are usually reported to exhibit defect tolerance in the bulk\cite{20-21}. Therefore, the surfaces, interfaces and grain-boundaries are usually the main concerns for optimizing the device performance. The surface properties of Cs$_2$SnI$_6$, which are expected to play an important role in the devices, remain poorly understood. Recently, several groups have devoted to the study on the surfaces of Cs$_2$SnI$_6$. Kapil et al.\cite{22} suggested the existence of the surface state in Cs$_2$SnI$_6$. Shin et al.\cite{21} investigated the role of the surface states in the presence of a redox mediator\cite{23}. Xu et al.\cite{24} reported a general approach to synthesize layered nanoplatelets of Cs$_2$SnI$_6$. Zhu et al.\cite{25} revealed that Cs$_2$SnI$_6$ crystals have a preferential growth of (111) surface. Several experiments also found that Cs$_2$SnI$_6$ tends to grow along the <111> direction\cite{26-28}. However, it is not clear that this preference is thermodynamically driven or just a result of growth condition specific to individual experiments.

In this work, as motivated by the experimental works,

we study the surface properties of Cs₂SnI₆ using first-principles calculations. As an initiative work, we attempt to understand the preference to the (111) surface in different crystal growth experiments. We set up different surface models with different surface orientations and terminations to compare their thermodynamic stability. As some terminations are non-stoichiometric, to evaluate their relative stability it is necessary to calculate the chemical potentials to consider the crystal growth conditions. By analyzing the surface stability, it is expected to provide useful information for future experimental synthesis and device fabrication.

1 Computational method

Our first-principles calculations were based on density functional theory and performed using the Vienna Ab initio Simulation Package (VASP) [29]. Projector augmented wave (PAW) potentials were used to describe the interaction between ion cores and valence electrons [30]. The strongly constrained and appropriately normed (SCAN) functional in combination with the rVV10 van der Waals (vdW) functional was used for the exchange-correlation functional [31]. The cutoff energy of planewave basis set was taken to be 340 eV and the Γ-centered 3×3×3 k-point mesh was used for optimizing the 9-atom primitive cell of Cs₂SnI₆. A cutoff energy of 272 eV and a Γ-centered 3×3×1 k-point mesh were used for the surface calculations.

2 Results and discussion

Experimentally, it is reported that bulk Cs₂SnI₆ exhibits a cubic structure with Fm-3m space group symmetry, as shown in Fig. 1(a), and the lattice parameter \(a₀\) is 1.165 nm [20]. Our calculated \(a₀\) using the SCAN+rVV10 functional is 1.156 nm, 0.8% smaller than the experimental value. The SCAN functional without considering the vdW effect yields \(a₀ = 1.178\) nm, 1.1% larger than the experimental value, suggesting that the vdW effect is significant for Cs₂SnI₆. As a comparison, we also considered the commonly used PBE and HSE functional, which yield \(a₀ = 1.203\) and 1.197 nm, respectively. The reason for this large vdW effect is that the material is rather soft. The calculated bulk modulus using the SCAN+rVV10 method is only 13.1 GPa. Using the other functionals mentioned above would yield even smaller bulk modulus.

![Fig. 1 (a) Atomic structure and (b) band structure and projected density of states (pDOS) of Cs₂SnI₆](image)

The band structure and projected density of states (pDOS) of Cs₂SnI₆ were calculated, as shown in Fig. 1(b). The direct gap at the Γ point is 0.19 eV, significantly smaller than the experimental band gap of ~1.3 eV, suggesting that the meta-generalized gradient approximation is not sufficient for studying band-gap-sensitive properties of this material, for which the HSE functional including spin-orbit coupling will be necessary [20]. According to the pDOS plot, the top valence bands are mainly contributed by I 5p orbitals, while the bottom conduction bands are contributed by both I 5p orbitals and Sn 5s orbitals. The Sn 5s orbitals form a separate band, above which is another band gap and the Sn 5p bands.
We next study the surface properties. We adopt the symmetric slab models for the surfaces, which possess a mirror symmetry through the middle of the slabs. Such models also avoid spurious interaction between periodic slabs due to dipole-dipole interactions. For all calculations, sufficient vacuum region (more than 1-nm-thick) was used to ensure negligible interaction between the slabs. Seven different terminations of Cs$_2$SnI$_6$ surface models were considered, as shown in Fig. 2. The non-stoichiometric (001) surfaces were modeled with CsI$_2$-terminated (or A-termination) and SnI$_4$-terminated (or B-termination) slabs, whose unit-cell formulae were Cs$_2$I$_2$SnI$_3$ and Cs$_3$SnI$_5$, respectively. Similarly, the non-stoichiometric (011) surfaces were modeled with I$_3$-terminated (A-termination) and Cs$_2$SnI$_2$-terminated (B-termination) slabs, whose unit-cell formulae were Cs$_2$I$_2$SnI$_4$ and Cs$_5$SnI$_7$, respectively. Along the [111] direction, the atomic stacking sequence is Sn–CsI$_3$–CsI$_3$–Sn–. Correspondingly, the non-stoichiometric Sn-terminated (A-termination), non-stoichiometric CsI$_3$-terminated (B-termination) and stoichiometric CsI$_3$-terminated surfaces were modeled, whose unit-cell formulae were Cs$_5$SnI$_7$, Cs$_2$I$_2$SnI$_4$ and Cs$_5$SnI$_7$, respectively.

We first evaluate the cleavage energy, which is the energy required to split a crystal into two complementary non-stoichiometric terminations. It is noted that CsI$_2$- and SnI$_4$-terminations for Cs$_2$SnI$_6$ (001) surfaces are mutually complementary, and so are I$_3$- and Cs$_2$SnI$_2$-terminated slabs for (011) surfaces, as well as Sn- and CsI$_3$-terminated slabs for (111) surfaces. As the two complementary surfaces (also referred to as A- and B-termination above) are created simultaneously when a crystal is cleaved, the total cleavage energy of two complementary surfaces can be obtained by

$$E_{\text{cl}}(A + B) = \frac{1}{2S} \left[ E(A)_{\text{unrel}} + E(B)_{\text{unrel}} - nE_{\text{bulk}} \right]$$

(1)

where $E(A)_{\text{unrel}}$ and $E(B)_{\text{unrel}}$ are the energies of unrelaxed A- and B-terminated slabs, respectively. $E_{\text{bulk}}$ is the energy per unit cell, $S$ represents the surface area and $n$ is the total number of bulk unit cells in the two slabs. Next, the relaxation energy of A-terminated surfaces with both sides relaxed is calculated according to

$$E_{\text{rel}}(A) = \frac{1}{2S} \left[ E(A)_{\text{rel}} - E(A)_{\text{unrel}} \right]$$

(2)

where $E(A)_{\text{rel}}$ is the energy of A-terminated slab after relaxation. $E_{\text{rel}}(B)$ is calculated similarly. Finally, the total surface energy of the two complementary surfaces can be obtained as the sum of the cleavage and relaxation energies:

$$E_{\text{surf}}(A + B) = E_{\text{cl}}(A + B) + E_{\text{rel}}(A) + E_{\text{rel}}(B)$$

(3)

The calculated results of total cleavage energy, total relaxation energy and total surface energy of the two complementary non-stoichiometric terminations with different surface orientations are shown in Fig. 3. For
comparison, the cleavage, relaxation and surface energies of the stoichiometric CsI-terminated (111) surface are also shown. It can be seen that the total surface energies of the two complementary non-stoichiometric terminations are relatively high compared with that of stoichiometric CsI-terminated (111) surface whose surface energy is only 0.11 J/m², regardless of the surface orientations. However, the contributions to the cleavage energy from the A- and B-terminations are not equal. Further study is needed to determine whether A- or B-termination could individually have surface energy lower than 0.11 J/m². In order to evaluate the relative stability of each surface terminations under various experimentally preparation conditions, the consideration of chemical potential $\mu_{\text{Cs}}, \mu_{\text{Sn}}$ and $\mu_{\text{I}}$ is necessary[21,32].

Through varying the chemical potentials, different experimental conditions can be simulated. The relative values of the chemical potentials of Cs, Sn and I are introduced with respect to their most stable phases, $\Delta \mu_{\text{Cs}} = \mu_{\text{Cs}} - \mu_{\text{Cs}}^{\text{bulk}}, \Delta \mu_{\text{Sn}} = \mu_{\text{Sn}} - \mu_{\text{Sn}}^{\text{bulk}}$ and $\Delta \mu_{\text{I}} = \mu_{\text{I}} - \frac{1}{2} \mu_{\text{I}}^{\text{bulk}}$. The chemical potentials of Cs, Sn and I are constrained by the calculated enthalpy of formation of the primary phase Cs₂SnI₆[33-34]

$$2 \Delta \mu_{\text{Cs}} + \Delta \mu_{\text{Sn}} + 6 \Delta \mu_{\text{I}} = \Delta E_f (\text{Cs}_2\text{SnI}_6)$$ (4)

where $\Delta E_f (\text{Cs}_2\text{SnI}_6)$ is calculated to be $-9.16$ eV. The chemical potentials are further subject to specific bounds that are set by the existence of secondary phases: $\Delta \mu_{\text{Cs}} + 3 \Delta \mu_{\text{Sn}} + 3 \Delta \mu_{\text{I}} \leq \Delta E_f (\text{CsSnI}) = -5.0$ eV (5) $\Delta \mu_{\text{Sn}} + 4 \Delta \mu_{\text{I}} \leq \Delta E_f (\text{SnI}) = -1.70$ eV (6) $\Delta \mu_{\text{Sn}} + 2 \Delta \mu_{\text{I}} \leq \Delta E_f (\text{SnI}) = -1.37$ eV (7)

$$\Delta \mu_{\text{Cs}} + 3 \Delta \mu_{\text{I}} \leq \Delta E_f (\text{CsI}) = -3.76 \text{ eV}$$ (8)

$$\Delta \mu_{\text{Cs}} + \Delta \mu_{\text{I}} \leq \Delta E_f (\text{CsI}) = -3.51 \text{ eV}$$ (9)

The enthalpies of formation above were all obtained by SCAN+rVV10 calculations. By considering these constraints, the final allowed region for $\mu_{\text{Sn}}$ and $\mu_{\text{I}}$ is demarcated by the points A, B, C, D and E, where equilibrium growth of bulk Cs₂SnI₆ is possible, as shown in Fig. 4.

Using the determined chemical potential region, the surface energy for each individual termination can be obtained using[35-36]

$$E_{\text{surf}}(A) = \frac{1}{2S} \left[ E_{\text{slab}}(A) - N_{\text{Cs}} \mu_{\text{Cs}} - N_{\text{Sn}} \mu_{\text{Sn}} - N_{\text{I}} \mu_{\text{I}} \right]$$ (10)

where $E_{\text{slab}}$ is the total energy of relaxed A-termination, $N_{\text{Cs}}, N_{\text{Sn}}$ and $N_{\text{I}}$ are the number of Cs, Sn and I atoms in the slab, respectively. Considering the variation of chemical potential with reference phase as mentioned above, the surface energy can be finally rewritten as

$$E_{\text{surf}}(A) = \phi(A) + \frac{1}{2S} \left[ \frac{N_{\text{Cs}}}{2} - N_{\text{Sn}} \right] \Delta \mu_{\text{Sn}} + \frac{1}{2S} \left( 3N_{\text{Cs}} - N_{\text{I}} \right) \Delta \mu_{\text{I}}$$ (11)

with $\phi(A) = \frac{1}{2S} \left[ E_{\text{slab}}(A) - N_{\text{Cs}} \mu_{\text{Cs}} + \frac{N_{\text{Cs}}}{2} E_{\text{bulk}} + \frac{1}{2} \left( 3N_{\text{Cs}} - N_{\text{I}} \right) E_{\text{bulk}} \right]$ (12)

Here, $\phi(A)$ is a constant term, independent of the chemical potentials. Considering that surfaces will spontaneously form and the crystal will be destroyed if surface energy is negative, it is necessary to satisfy $E_{\text{surf}}(A) > 0$. 

![Fig. 3 Calculated total cleavage, relaxation and surface energies of two complementary non-stoichiometric terminations in (001), (011) and (111) orientations, which are compared with the cleavage, relaxation and surface energies of the stoichiometric CsI-terminated (111) surface](image-url)

![Fig. 4 Illustration of the accessible chemical potential region for Cs₂SnI₆](image-url)
Fig. 5 Stability of low-index surfaces of Cs$_2$SnI$_6$ as a function of chemical potentials

(a) Analysis of stability of the two terminations of Cs$_2$SnI$_6$ (001) surface with respect to the allowed region for maintaining equilibrium with the primary phase Cs$_2$SnI$_6$. The orange and blue regions indicate the stable region for CsI$_2$- and SnI$_4$-terminations, respectively. (b) Similar to (a) for the Cs$_2$SnI$_6$ (011) surface. The orange and blue regions are for the I$_4$- and Cs$_2$SnI$_2$-terminations, respectively. (c) Similar to (a) for the Cs$_2$SnI$_6$ (111) surface. The orange and blue regions are for the SnI$_4$- and stoichiometric CsI$_3$-terminations, respectively. (d) Surface energies of the seven surface models of Cs$_2$SnI$_6$ as a function of the chemical potentials.

The stability diagram of the Cs$_2$SnI$_6$ (001) surface is shown in Fig. 5(a). The blue and orange regions represent the regions where CsI$_2$- and SnI$_4$-terminations are stable, respectively. The upper part of the green region is located in the blue region, indicating that the CsI$_2$-termination is favored under the I-poor condition. There is still a small part of the green region located in the orange region, e.g., at chemical potential points C and D, indicating that the SnI$_4$-termination is more stable than the CsI$_2$-termination under I-rich condition.

Similarly, the stability diagram of the Cs$_2$SnI$_6$ (011) surface is shown in Fig. 5(b). The blue region represents that the Cs$_2$SnI$_2$-termination is thermodynamically more stable, while the orange part refers to the region where the I$_4$-termination is more stable. It can be seen that the green region is also located in both blue and orange regions, indicating that different terminations are favored when varying the experimental environments. Under I-rich condition (e.g., at chemical potential point A) the Cs$_2$SnI$_2$-termination is favored, while under I-poor condition (e.g., the chemical point D) the I$_4$-termination is favored.

In Fig. 5(c), we show the stability diagram of Cs$_2$SnI$_6$ (111) surface. Different from the stability diagrams of the (001) and (011) surfaces discussed above, the whole
green region is located in the orange region for the (111) surface, indicating that the stoichiometric CsI$_3$-terminated (111) surface is the most energetically favored among the three terminations regardless of the chemical potentials.

Finally, the surface energies of the seven terminations of Cs$_2$SnI$_6$ low-index surfaces are compared in Fig. 5(d) as a function of the chemical potentials. It can be seen that the stoichiometric CsI$_3$-terminated (111) surface consistently has the lowest surface energy, indicating that it is the most thermodynamically favored surface among the seven terminations, in agreement with the recent experimental reports.$^{[25-26]}$

3 Conclusion

Based on density-functional theory calculations with the SCAN+rVV10 functional, seven models for the low-index Cs$_2$SnI$_6$ surfaces were studied with different surface orientations and terminations to compare their thermodynamic stability. Overall, based on the calculated surface energies, we identified that the stoichiometric CsI$_3$-termination for (111) surface is consistently the most stable, regardless of the chemical potentials, which is in agreement with the experimental observation that the (111) surface is often the most exposed surface. For the (100) and (110) surfaces, two different terminations were considered for each of them. Their relative stability depends on the chemical potentials. From an experimental point of view, when preparing these two surfaces, one can obtain different terminations by varying the growth condition, e.g., by controlling the I-poor or I-rich conditions.

**摘要**：Cs₃SnI₆是一种稳定且环保的卤化物钙钛矿材料，在光伏和光电应用方面具有巨大潜力。虽然表面性质对于光电器件的制备至关重要，但目前尚没有对该材料开展相关的理论研究。使用密度泛函理论计算结合SCAN+rVV10泛函，我们研究了Cs₃SnI₆的(001)、(011)和(111)表面以揭示其热力学稳定性。针对每个表面，我们考虑了具有不同截断的模型，包括两个沿(001)方向（分别为 CsI₆和Sn终止的表面）, 两个沿(011)方向（分别为L₈终止的表面）和三个沿(111)方向（分别为准化学计量比的CsI₆，Sn和准化学计量比的CsI₆终止的表面）。由于大多数表面模型的化学计量比的，它们的相对稳定性取决于实验制备条件，因此需要考虑组成元素的化学势。通过确定允许的化学势区域，我们分析了这些表面的热力学稳定性。结果表明，(001)和(011)面的表面能会受到化学势的影响，而满足化学计量比的CsI₆终止的(111)面不受化学势影响，是Cs₃SnI₆最稳定的表面。该结果说明这类实验普遍观察到的暴露(111)面的晶体是受热力学稳定性驱动所致。
